All points considered, I fancy it would be difficult to find a more showy and useful genus of flowering shrubs than the *Berberis*. The species and varieties are all easily grown, and when once they become established produce a fine display of blossom each year. Seasons seem to affect them but little, for their flowers come and go with unfailing regularity. *Darwini* is a species which should be grown in every garden where there is room for one *Berberis*, as it forms a densely branched handsome shrub, which is most attractive at all times. The flowers are of a bright orange colour, and are produced in wonderful profusion on gracefully arching branches. Plant it if possible on a bank in a sunny position; it will then thrive well, and display its charms to the best advantage.

B. buxifolia, better known as *dulcis*, is an exceedingly elegant kind, which produces long slender shoots, and leaves of a fresh green colour; the latter associate well with the soft yellow colour of the flowers. The plants should be given a good position, as they are not so well able to take care of themselves as are those of *Darwini*. *Nana* is a pretty form of *dulcis*, which seldom grows more than 2 feet high. *Stenophylla* is a fine variety for planting upon a rockery—on a bank, where it can be kept clear of stronger-growing shrubs. It never attains a great height, but sends out long graceful shoots, which in time droop almost to the ground. It may be correctly termed a pendulous variety. Of the well-known *aquifolium* there are several forms, the principal difference between them being in the size and style of their leaves. All are excellent for planting as a fringe to shrubberies, for covering banks, or unsightly places under the shade of trees.

By pruning the plants annually, just before growth begins, they quickly form a dense mass, and may if required be kept to a foot in height, or if necessary they will reach a height of 5, and yet present a dense leafy surface. *B. japonica* and *B. nepalensis* are both handsome varieties, of upright habit of growth, which produce very large leaves. They should be planted in deep rich soil, in a somewhat shady position.

Buddlea globosa is unfortunately not often met with, doubtless because it is somewhat tender but if given the protection of a wall and a south aspect, only our most severe winters injure it fatally. Its flowers are so unique in appearance that they are worth taking some trouble to secure. *Choisya ternata* is another neglected shrub, which bears a profusion of strongly scented white flowers, much resembling Orange blossom. I consider it to be perfectly hardy, as we have a large plant growing on a wall that sweeps round to the east, at a point where the wind sometimes catches it with tremendous force, yet this plant was not materially injured during the severe winters of 1893 and 1894. Cuttings root quite easily, so there is really no valid reason why this scented shrub should not be universally grown.

Cistus ladaniferus (Gum Cistus) with its cup shaped, delicate white flowers should be grown wherever a small space of wall, having a sunny aspect, can be spared. *C. l. maculatus*, *C. creticus*, and *C. florentinus* are also good varieties.

Good specimens of *Desfontainea spinosa* are sometimes met with in the south-western counties, and, although I am not sure if it is quite hardy in the Midlands, it is certainly worthy of being given a trial on account of its great beauty when in flower.

Daphne Laureola (Spurge Laurel) is a well-known low-growing shrub, useful for growing under the shade of trees, as the shoots branch freely, and are very pliable by pegging-down; a single plant will in time cover a large space and be kept quite dwarf. *Pontica* is highly prized on account of the delicious fragrance the flowers

emit, especially in the evening; for this reason it should be freely planted in various positions.

Fully expanded flowers or opening buds may usually be seen on the *Laurustinus* at Christmas, unless the weather is exceptionally severe. After very sharp winters many of the older branches are killed to the ground line; it should therefore, if possible, be planted in a rather sheltered position. *Frobeli* is a very compact form, bearing pure white flowers, and judging by the behaviour of the few plants we have of it, it is hardier than the common form.

Among the *Ligustrums* (*Privets*) *lucidum* and *l. coriaceum* are two of the most showy; the former flowers in early autumn and the latter in June or July. Each bears large panicles of white or greenish white flowers.

Like many other indigenous plants the several varieties of *Ulex* are extremely showy, and well adapted for planting in gardens. Good dwarf bushes are always telling when in flower if situated in the foreground of shrubberies, but to my mind their great value lies in their capacity for clothing dry banks where the soil is poor, and perhaps interlaced with tree roots. In almost every garden places of this description exist, where many things have been planted with but poor results. To all who have a difficulty of this kind to overcome my advice is insert at once seeds of *Ulex europæa nana*; do not be sparing of seed, and when the young plants appear keep them free from weeds. By doing this you will in the course of a few years be able to convert an unsightly spot into one presentable in appearance at all times, and which in the early spring months will be a vision of golden beauty.

Many of the *Veronicas* are pretty dwarf shrubs, unfortunately not quite hardy. What a gem *Andersoni variegata* would be were it perfectly hardy! In sheltered positions I have known plants thrive well for a few years, but they have always succumbed to severe winters at last. *Traversi* is, therefore, the only one I recommend for planting, except in especially favoured districts.

In drawing these notes to a close I am tempted to express the hope that they may be the means of directing attention to the desirability of planting more extensively the good things sent us from foreign lands, so that this fair island may be made fairer still. We all, I think, must sometimes read with envy the graphic descriptions given by travellers of the floral beauties to be met with in more sunny climes; but methinks that England may be made as bright and beautiful as any, seeing from how many countries we obtain shrubs which will blossom in full glory here.

Botanical collectors have done their part towards the achievement of this result by expending their energy and risking their lives to send us the best the world can give. To complete the work the mutual efforts of gardeners and their employers are required, for if the latter contribute some of their wealth towards the project, and the former select, plant, and cultivate intelligently, time and a bountiful Creator will do the rest.—H. DUNKIN, *Castle Gardens, Warwick*.

THE MISSION OF FLOWERS.

FOR surely flowers have a mission, if it be but to assure, to comfort, and to cheer. It is not only nectar for bee and butterfly, and seed for birds, but variety, beauty, and fragrance for the wayside embellishment, so that he who runs may read. The more we take delight in the study of Nature the more we appreciate and enjoy it. Sir Thomas Browne speaks wisely on this subject. "The wisdom of God," says he, "receives small honour from those vulgar heads that rudely stare about and with a gross rusticity admire His works, those highly magnifying Him whose judicious inquiry into His acts, and deliberate research into His creatures, return the duty of a devout and learned devotion." Most of us enjoy beauty of form and colour and sweet odours. What can one have more beautiful than even our common wild flowers—the chaste elegance of the peerless Lily of the Valley and the wreaths of the fragrant Wild Rose? Were the humble wildings that carpet our woodlands, and garland our hedges, and put a bordering of *Myosotis* and *Meadow Sweet* along our riversides less abundant, we should perhaps admire and esteem them more. But, alas! our children are too much occupied at school in the wretched routine of the so-called education given that there is no time to "consider the Lilies."

I cannot help thinking at times of that Carpenter's Son who, with his faithful followers, "downhearted," as country folk say, passed through the fields of Galilee, rubbing now and again the ears of corn in their hands, as they were allowed to do by their code of laws. "Knowing their thoughts," he pauses by the way to utter those few poignant words, "Consider the Lilies, how they grow!" And surely the humblest florist must be convinced of the absolute truth that "even Solomon in all his glory was not arrayed like one of these." Glance into the corona of the wild *Narcissus*,

bespangled with crystals of gold, or the sculptured snow of the Lily of the Valley, or the ultramarine in the throat of the Gentian, was it only for bee and butterfly that these were thus "clothed?" What a boon for the London poor is the presence of Covent Garden in their midst! Not merely for the employment it provides, but the comfort and cheer of the crowded streets. Those masses of many golden tones that decorate our streets, the Daffodil—what a treat it is to rest the eye on them, and pause for a moment to inhale the refreshing fragrance! Morning after morning fair Flora's fountain overflows, and even the grimmest thoroughfare is enlivened and sweetened by the breath of flowers. To the poor labourer, forced through lack of employment on the soil to seek the means of sustenance in crowded London, what happy reminiscences do the flowers bring of his village home with his little cottage garden—the Violets, Stocks, and Gillivers, the Roses, Pinks, and Sweet Peas, the Lad's Love, Rosemary, and Lavender! How seldom is it that a bunch of flowers or a plant is to be seen in our great London Board schools! and yet what a treat it must be for weary teachers and the serried ranks of wearier children to rest the eyes for a few moments on a flower!—the one link between the dismal, noisy streets and the beautiful world beyond them.

The vast improvement in our London parks and gardens is another boon to the poor, another message from the flowers, and how greatly the delight would be enhanced by some knowledge of the flowers admired. There are at least three farm lads who were lovers of flowers, and wrote of them in unforgotten verse. Imagine Robert Burns stopping his plough in mid-furrow to apostrophise the "wee crimson tipped flower," that "bonnie gem!" Bloomfield and Clare, too. What a fund of unalloyed delight this love of flowers and Nature must have been to them. "I thank God," said an old friend, "for giving me this love of Nature. From the time I was a chubby 'four-year-old,' when I used to prowl round my father's cottage garden and into the adjoining meadows to gather wild flowers, or peer into the nest of the thrush and blackbird until now. It is a pleasure that ne'er grows old. The picture may tone with age, but it never loses its freshness and charm."

I remember giving a wee lassie a few Roses to take to her father in the hospital, and begged the Secretary's permission to glance through his window into the ward, where the poor fellow lay. It was a comfort and delight to him—a flower, a Rose. But on the opposite side of the room a poor pale-faced lad was watching with longing eyes. At last he must speak perforce. "Do give me one bud, little lass! Our folks know how fond I am of flowers, and yet they never send me one. They won't come to-day!" The father culls an opening bud from the little bunch, and gives it to his daughter. "Tek it to him, Sue." Then Sue, with a deeper blush on her already rosy cheek than that of the Rose, hurries across and gives him the flower. "Thank you, my dear," said he, looking across at his co-patient—the father. How the poor lad gazed into its deep recesses, and drank of the fragrance in eager draughts until gentle sleep fell on his weary eyelids, after giving one grateful glance at the child and her father.

It was a bud half open of the dear old Provence, the Cabbage Rose of cottage gardens, the most fragrant of all the tribe. One doesn't hear so much of the so-called "flower missions" as years ago. I fear it is because the recipients are so much lectured and pestered with good advice that the gift is less welcome. The flower can tell its own tale perhaps; a flower worth the giving, a kindly look, a gentle pressure of hand, and then a word in answer to the "Do come again, friend." "Yes, certainly, and I'll bring you another Rose." I have known such—there are more of them than some good folk believe.

John Burroughs, the delightful American writer, twice at least paid us a visit, once to see our wild flowers at home and again to hear our nightingale. He urges the beauty of American wild flowers, but is compelled to admit the splendour and vast profusion of our common wildings; acres of Primroses carpeting our woodlands with their green and gold, and acres, too, of wild Hyacinth stretching away down through the vistas of the woodland, bluer than Italian skies; miles of stately Foxglove, which seemed to delight him even more; long lines of foamy Meadow Sweet, huge rafts of Lilies, and the infinite variety and tones of the spring verdure.

Now in London there is not, perhaps, one room in a hundred in which even a green leaf may be seen, much less a flower. And what is worse, there seems to be no desire for it. And yet there is not a window sill in the gloomiest of London courts that might not bear its burden of a box or pot of flowers, in spring and summer at least. Now this love of flowers might be begotten and cherished in the schoolroom. But pause a moment. What would the stingy folk say whose only object in securing a seat on the School Board or management is to consider the ratepayers? What would such folk say were someone to suggest window-boxes for schools?

One may almost imagine the indignant scorn of those who begrudged a piano to accompany the singing. Music and drawing and flowers! What are we coming to?

There is no more delightful and instructive recreation than the cultivation of flowers, and the greater the difficulties encountered and overcome, the greater the satisfaction and delight. One thinks of the naked dingy walls of our London Board school playgrounds, and the few pence in a hundred pounds properly expended that would invest them with interest and significance. Why should not these be utilised as wall gardens? Ivy, Virginian Creeper, and Euonymus would grow on walls with any aspect, and, for at least four months of the year those pretty annuals *Nasturtium*, Canary Creeper, and *Convolvulus*, would serve to cheer and lighten the grimy and repulsive surroundings.

Another circumstance suggests itself. There are thousands of country houses unoccupied for a portion of the year—the London season—when acres of flower beds are left to waste their sweetness on the "summer air." There is a society in London—or was—whose function it was to embellish the school-room walls with works of art, to put before the eyes of children "things of beauty" in the way of pictures. Now, what picture could be compared for a moment to a healthy plant in a pot, or a vase of flowers? Such a society might be the means of suggesting to the owners of country houses the delight they could provide at a mere trifle of expense to poor town children.

And then, when the woodlands, and fields, and hedgerows are spattered over with wild flowers in April, May, and June—acres of Primroses and Hyacinths, and miles of fragrant Hawthorn to be had for the gathering, what a pleasure it would be to the teachers to distribute these, and thus help forward the mission of the flowers! Some day it is to be hoped every school in town as well as country will have its garden, if it be but a strip of the playground, where something green may live and grow; then, at least, something more may be hoped from the mission of flowers.

—HERGA.

ROYAL HORTICULTURAL SOCIETY'S COMMITTEES' AWARDS.

REALLY I cannot for one moment admit the correctness of the deductions of "F. R. H. S." in relation to my comparisons of the liberal awards made by the Council at York and Chester, and those of the Committees at home. He places for comparison the awards at the Temple Show of last May (sixty), as against those of the Council at York and Chester (seventy-two) at two shows. But then, how diverse the conditions at the Temple Show; not a single money prize is given, and the awards (sixty) include almost everything exhibited. To have made the comparison even, "F. R. H. S." should have included the prizes awarded at the two provincial shows.

That is enough on that point. As to the proposition that every member should be compelled to vote on a proposed award one way or another, I see no objection, but I do not think the present too free making of awards would be restricted in the least. On the Orchid and Fruit Committees members are supposed to be such because they have some knowledge of all the subjects which come before them. On the Floral Committee, where many members are specialists only, the case is different, and might lead to difficulties. It is no fault of mine that awards are so freely made. I still hold that the Council in complaining should have gone farther and told the Committees how to avoid this liberality.—A. D.

[That is what "F. R. H. S." seems to think, and we are disposed to agree on the point. It is not the first time the Council has complained ineffectually without suggesting a practical remedy. "A. D." omits reference to the two-thirds majority proposition, perhaps accidentally.]

GOLDEN FOLIAGED PINES.

IT is the exception rather than the rule to find species or varieties of the genus *Pinus* with foliage of any other colour than green; a few, however, exist, and it is my wish to draw attention to two of the better of these as ornamental garden plants. The better known of the two is the golden form of our British Pine, *Pinus sylvestris aurea*. In exceptional instances plants of this variety are found growing freely, and having every appearance of making small trees; more often, however, the plants are stunted in growth, and make bushes a few feet high.

A plant of recent introduction, and one which appears to be of a more free growing disposition than the former, is the golden variety of the Japanese *Pinus Thunbergi*. The leaves of this are from 4 to 5 inches in length, quite 2 inches longer than those of *P. sylvestris*, and altogether the plant has a more elegant appearance than the first mentioned. Whether grown singly or in masses these golden Pines have a most striking appearance, and are well worth growing.

A variety of *Pinus Thunbergi* called *variegata* has recently been introduced, which has the leaves alternately banded with half-inch bands of green and yellow; it is not likely to become popular, however, as the yellow portions have a tendency to revert to green. Either of these varieties may be increased in spring by grafting on stocks of their respective species.—W. D.

GILIA BRANDEGEI.

THE annual Gilias are better known and more extensively grown than the biennial and perennial forms, though some of both of the latter are worthy of a place in every garden. *G. Brandegei*, the perennial species represented in the engraving (fig. 47) forms tufts of small 'peculiar and pretty leaves, alternate on the leafstalk; the flower stems are erect, from 6 to 8 inches in height, giving a succession of bright primrose-yellow flowers all through the summer and autumn. It is perfectly hardy, and seems to flourish best in a damp shady situation; if on rockery the natural drainage will be found sufficient. Planted out in a position where it can be treated liberally it attains a large size for a *Gilia*, forming in one year a clump from 1 to 2 feet in diameter. The young growths or side shoots may be struck readily under a hand-glass in August and September. It is a native of the Rocky Mountains of South Colorado.—GROWER.

MARCH PROPAGATING.

CHRYSANTHEMUMS.

MARCH is a very suitable time to propagate by cuttings all sections of *Chrysanthemums* when plants are wanted simply for decoration. There is even time to root plants for show purposes, especially those which are to furnish dwarf plants for grouping, or to reduce in height by cutting down low in May or June. Early rooted plants intended for the latter purpose cannot be cut down quite so low because the stems at the base are so much harder, and it is well known that woody leafless portions of stems do not break readily into growth. Hence we find the utility of spring rooting when plants are required to break as low as possible. By inserting strong cuttings of many of the exhibition varieties good plants, which will produce excellent flowers, may still be rooted, due regard being paid afterwards to the details of cultivation throughout the summer.

The late varieties form a valuable section because of their importance for December and January cutting, when flowers are naturally limited in quantity. Some excellent varieties have been mentioned for this purpose in previous numbers of the *Journal of Horticulture*. There can be little doubt that if more attention were paid to cultivating good stocks of the varieties recommended by the practical correspondents who have described the merits of the most suitable, a liberal display of bloom might be had at the period mentioned. This is a good time, then, to commence carrying out the ideas, thus enlarging the season and interest in *Chrysanthemums*. If cuttings are not easily obtainable, small rooted plants may be had in the course of the next few weeks from the trade growers. These are sure to do well when cuttings might fail, but the latter is a remote contingency at such a favourable period of the year for propagating.

Early *Chrysanthemums*, too, are much appreciated, and ordinary growers cannot do better than cultivate a quantity both in pots and borders.

Varieties that afford strong cuttings may be rooted in small pots singly. Small and weak cuttings are always best round the edges of larger pots. Quantities of one kind may receive accommodation in large pots and shallow boxes. Use sandy, light soil, and give simple treatment in a slightly moist heated temperature until roots have formed.

ZONAL PELARGONIUMS.

Insert strong cuttings singly in the centre of small pots, using sandy or gritty soil. Place in full sunshine on a warm shelf in an intermediate stove or warm greenhouse. One good watering will suffice for a time, as it is not desirable to maintain the soil too moist. When a little on the dry side the cuttings callus more freely and root sooner. Occasional light skiffs with the syringe afford sufficient refreshment. As soon as rooting does commence a more constant state of moisture in the soil is necessary.

As they advance in growth give cooler treatment. Nip out the tops when growing freely, so that bushy plants may be produced. Plants in quantity for bedding may be rooted round the edges of pots and transferred singly to 3-inch pots when well rooted. Spring propagation is chiefly resorted to for increasing stock of any particular variety, and to furnish plants for autumn and winter flowering in pots.

LOBELIAS.

Lobelias, blue and white, readily increase by cuttings at this season, when a stock of plants is at hand to commence with. Old plants potted in autumn and kept in a healthy condition furnish abundance of growths, which are constantly emitting roots while still remaining attached to the parent plants. These taken off and inserted will quickly become established plants. Little preparation of the cuttings is needed, but a few large bottom leaves may be removed. Insert as soon as possible, placing them thickly together in shallow pans, pots, or boxes filled with leaf soil, a little loam, and sand. Water in the cuttings with tepid water.

The receptacles should be placed in a moist bottom heat of 65°, maintaining a humid atmosphere about them. This is best secured by a moist base of cocoa-nut fibre, through which, if kept moist, the heat can rise. Frequently dew over the cuttings with the syringe. When well rooted and growing apace the tops can be taken off and rooted similarly, or constantly pinched to keep the growths compact and bushy.

FUCHSIAS.

Now that old plants of *Fuchsias* are commencing to make growth freely, numbers of stout, short-jointed cuttings may be secured. It is quite as well to root them thickly round the edges of small pots, and afterwards divide them into single plants, placing each in a small pot in good open soil. They also root freely in boxes, from which they may be transferred as readily as from pots. Soft young growths with a heel attached form very suitable cuttings, obtaining them when about 1½ to 2 inches long. Remove the bottom leaves, two pairs being sufficient for each cutting to carry. Insert in the soil to the bottom pair. The compost must be a light sandy mixture of loam and leaf soil. Surface with a layer of sand, and after insertion gently water the

FIG. 47.—GILIA BRANDEGEI.

cuttings. Place in a moist, warm temperature, shading from strong sunshine.

In a house that is regularly humid and warm, the cuttings can be maintained fresh without confining them closely in frames or under hand-glasses; but in a dry though warm structure this may be necessary and beneficial by assisting the maintenance of a regularly moist condition of the soil. It prevents rapid evaporation, which if excessive soon causes the foliage to droop. This destroys their chance of rooting, or at least retards them from doing so.

COLEUSES.

March is the best month to commence rooting a fresh stock of *Coleuses*. Old stock plants, or younger examples rooted in autumn for preserving through the winter, furnish the necessary growths. They should be, of course, the strongest obtainable. There is not, however, much difficulty with young wood which is freely growing, whether strong or weak; but the strongest make the best plants the soonest. *Coleuses* like plenty of heat and moisture, and without these essentials rooting cannot be insured. A fair amount of light must also be given from the first—in fact, unless the cuttings flag in sunshine, give no shade during the process of rooting. Almost any sort of sandy soil is suitable for

Coleuses when rooting. Afterwards give them something a little richer. Loam two parts, leaf soil one part, with sand and a little decayed manure, the latter when finally potting. Insert stout cuttings singly in 2½ or 3-inch pots, and weak ones round the edges. Coleus Verschaffelti, the variety used for bedding, may be rooted in quantity in boxes stood on hot-water pipes, frequently syringing to maintain them fresh.

PETUNIAS.

Vigorous young plants of Petunias may soon be obtained by inserting sturdy cuttings obtained from the base of old plants retained for this purpose through the winter. A number may be placed together in pots of convenient size, standing on a moist base in a propagating pit. Extra vigorous cuttings might each have a separate pot from which they can be transferred to larger without damaging the roots. Double varieties are the most useful for pots under glass. Single varieties are more floriferous for outdoor culture.

Other useful plants for bedding and pots include Heliotropes and Carnations, cuttings of which may be inserted now in a brisk bottom heat. All the tender bedding plants, such as Alternantheras, Iresines, Mesembryanthemums, Gazanias, and Marguerites can be rooted thickly in shallow boxes where they could stand on a row of hot-water pipes or be accommodated in a propagating pit or a gentle hotbed. It is an easy matter to give them more room when rooted in other boxes, in which they can remain until required for outdoor planting.—E. D. S.

WATER LILIES.

KEEPING Water Lilies through the winter is considered by many more difficult than growing them and producing first-rate flowers, but, as with many other plants, the more experience one has with the different varieties and their peculiarities the more simple their cultivation becomes. Of tropical or tender Nymphaeas, medium to small tubers are the best to carry over winter, but it sometimes happens that it is desirable to retain a certain plant or variety that has made extra large growth during the summer.

I had several such last season, and by way of experiment I tried what was to me a new method of wintering. After the frost had cut off the foliage I awaited a mild spell, and then with a spade dug around the plant; I gave it a root-pruning, taking care to keep outside of the tubers, so as not to cut them, then with a spade on each side lifted the stool intact. This was again planted in the soil, which is sandy, under the bench in the greenhouse, and thoroughly soaked with water. After a few days the roots were much decayed, and another soaking of water was given to settle the soil around the old crown and attached tubers. In this condition they were left, and on examination at this date (February 2nd) the tubers were in excellent condition, and will remain so for a long time. Even the hardy varieties treated in this way are keeping better than I had expected.

This treatment is not so well adapted to large plants of the stellata type, as they do not form side shoots and tubers. The best method for carrying these over winter is to keep them growing. These, though very large, were severely root-pruned, the largest leaves taken off, and potted into as small a pot as would hold them, which was 10 inches. The plants have kept growing slowly, and are now fine and healthy with flower buds. The water has been at a temperature of from 60° to 65°, which is the temperature of the house.

Such winter-flowering aquatics as Nymphaea stellata, N. zanzibarensis and N. pulcherrima have been in bloom all the winter. The latter variety is the best of any of the blue forms. The flowers open quite early in the morning, and remain open until late in the afternoon, whereas those of N. zanzibarensis seldom, if ever, open until noon or shortly before. Little can be expected in the line of Water Lily flowers during December and January, but N. delicatissima and a seedling much like N. Smithiana have not failed to produce flowers of good size and substance. N. O'Marana has proved a disappointment. It was hardly recognisable as the plant which I saw in such good form, condition, and colour out of doors last summer. N. devoniensis and N. rubra are better.

Aponogeton distachyon proves a first-rate winter-flowering plant. It enjoys a temperature of 50° to 60°, and blooms freely all through the dull sunless days. The flowers are sweet-scented, resembling Hawthorn, and are good for cutting.

We have decided to raise some Water Lilies from seed, and as it takes between three and four months to grow a flowering plant from seed, the sowing must be done at once, of both hardy and tender varieties; 4 or 5-inch pots should be used for the purpose, and sandy loam. If the latter has lain some time and had manure composted with it so much the better, and fresh manure should not be used. The seed should be covered lightly after it is sown, and the pots stood in water until the seed is thoroughly soaked. The pots should be submerged so that the tops are 2 inches below the water. Attention to this particular is necessary, or the seed will not germinate. The temperature of the water should be from 75° to 80°. Victoria regia seed may be sown now, but the temperature of the water must be 85° to 90°, and from twenty to thirty days is required for germination. The young seedlings should be transplanted at an early stage, and kept steadily growing. They must be repotted singly before they are weakened by overcrowding and starving conditions.—W. TRICKER (in "Garden and Forest.")

A. K. WILLIAMS.

IN my article on page 188, that beautiful variety A. K. Williams is by mistake described as "the least faultless in form of the Hybrid Perpetuals." I regret this error, for it is, in my opinion, the most perfect of them all.—DAVID R. WILLIAMSON.

MRS. R. G. SHARMAN CRAWFORD.

ALLOW me to fully endorse the favourable opinion passed upon this Rose by Mr. Williamson on page 188. Having grown it since the first year of introduction, I know of no Rose that has given me greater delight. For freedom of bloom, form of petal, and charm of colour it is a Rose that one can never tire of, and one that should be in every collection throughout the kingdom. Though coming into bloom somewhat early with us, it is again one of our best autumn-flowering varieties, and last year we cut handsome blooms in November. There can be no two opinions as to its being a worthy companion to Mrs. J. Laing.—R. P. R.

HYBRID TEA ROSES.

THE following is an extract from a letter addressed to the Editor of the Journal from one of Her Majesty's Judges at Alexandria:—"Neither I nor any of my neighbours know the difference between a Hybrid Tea and a Hybrid Perpetual, or again between a Tea and a Hybrid Tea, except that the Perpetual flowers more often than the others. We look up the names in a nurseryman's catalogue, and then, of course, we hope we are right; but there must, I suppose, be some classification of the different Roses, and there must be something in the thorns, the growth, and the stems of the flowers that makes an expert know under what category they ought to come."

Now this letter is "nuts" to me, because it is an indication of the confusion that I was sure would arise when the attempt was made to form a new section of the autumn-flowering Roses—namely, that of Hybrid Teas. I think there is no definition which would be explanatory. Were there one I should remember the cautions given to me by a master of logic in my early days (Archbishop Whateley)—"Avoid definitions."

The first of this class which appeared in our catalogues was Cheshunt Hybrid, raised by Messrs. Paul & Son of Cheshunt, believed to be a cross between Madame de Tartus and Prince Camille de Rohan; for years it stood alone, and then we were very much astonished to find that that beautiful Rose La France, which had been sent out by Guillot in 1867, and had always been classed with and exhibited amongst Hybrid Perpetuals, was suddenly shifted over into the Hybrid Tea class.

Hybrid Perpetuals is a misleading name; the French name for them, Hybrides remontants, is much more correct, as distinguishing them from the early summer-flowering Roses, which make their wood after flowering without any buds, whereas the so-called Hybrid Perpetuals give a second bloom from the young wood of the year. There is no doubt that the blood of various classes of Roses have entered into their constitution, but at the same time it would be very difficult to give any definition of them, and the special name by which they are known has only reference to the one point of second blooming. The word certainly gives nothing by which their position can be defined, as in some cases the wood is perfectly smooth and in others very thorny.

Teas have all a peculiar foliage, which, though it may not be easy to describe, is yet easily recognised, and they are perhaps the most truly "remontante" of any sections. If then, as I have said, one can give no definition of what a Hybrid Perpetual is except in the reference to one point, I think it is equally impossible to define what a Hybrid Tea is; and in fact there is a difference of opinion as to the position of some of them. Thus the late Mr. George Prince maintained that Kaiserin Augusta Victoria was in all points a true Tea. It will thus appear that your correspondent is not likely to get the accurate and definite explanation that he wishes. However, the N.R.S. has published in its catalogue a list of flowers which it has recognised under this title, and I shall have much pleasure in forwarding him a copy, which may perhaps serve his purpose.

With regard to that list I may add a few words. That the catalogue comprises ten exhibition varieties and ten garden Roses, while in the supplement there are five exhibition and four garden varieties. Thus the exhibitor who wishes to contend in the special class for Hybrid Teas has only fifteen to choose from, and it is curious to see how these are made up. I have already said that La France for a number of years was counted as a Hybrid Perpetual; now it, Gustave Guinoisseau, Danmark, and Duchess of Albany, three sports from it, are included in the ten exhibition varieties in the Hybrid Tea class. Then, again, Captain Christy, ever since its introduction, until the last year or two has been regarded as a H.P., but is now found in this class.

In the same way Lady Mary Fitzwilliam and Viscountess Folkestone have been taken out of the Hybrid Perpetual class and placed here, while Caroline Testont has been regarded by some as another sport of La France. The same may be said of Mrs. W. J. Grant, which was first exhibited as a Hybrid Perpetual, and I confess that I can see no trace

of the Tea in it. We were told a little while ago that this was the coming class, and yet since 1891 there have only been three added to it.

Perhaps those who are very anxious to extend it will see if they cannot plunder the Hybrid Perpetual class of some more Roses. I do not wish to be mistaken. Many of these Roses are very beautiful. My objection is not to the Roses themselves, but to the position they are made to occupy. I have been led into somewhat of a digression from your correspondent's questions; but the subject was a tempting one to me, for I am considered somewhat of a heretic in the matter, and although your correspondent may perhaps be disappointed I have done the best I could for him.—D., Deal.

FUCHSIA JOTTINGS.

FLOWERS, like books, captivate in varying degrees, some causing quite a craze and taking the world, as it were, by storm; others attracting little or no attention, and others still creating and preserving a reputation that wavers not amid the ups and downs of fashions and fancies. In the latter section the ever-popular Fuchsia is a prominent figure. Before the present race of horticulturists sprang into existence the plant found favour in the eyes of all sorts and conditions of gardeners, and if I mistake not it will hold its sway when this generation is numbered amongst the past. Turn to the early volumes of the old *Cottage Gardener*, and you will find its praises sung by able gardeners who were also able writers, and although the then brief list of varieties has been largely augmented at the hands of the hybridising florist, the principles of culture are the same, and withal so well known that to attempt to teach would only be going over the track now so well trodden, therefore I will be content with a few reminders.

One of the most pleasing features about the Fuchsia is that it does not, like many other plants, only bring pleasure to the favoured few, but adapts itself to varying conditions of cultivation. It is a window plant in the true sense of the word, and behind the casements of the meanest and most obscure cottages are annually grown plants that would do themselves credit in any conservatory. In village home life too the Fuchsia plays its part, and well do I recollect the merits of a certain Lucy Finnis that had been begged as a "slippin'" by a rural postman, and grew and prospered till the plant became a byword amongst the cottage gardeners in the country round. Favoured admirers in turn were provided with cuttings from the famous "Lucy," and in course of time the majority of windows in the village were ablaze with flowers that owed their origin to the postman's "slippin'." I will not attempt to illustrate the excitement at the village show when the plants were pitted against each other in competition for the coveted first prize card.

All honour then to a plant, old though it be, that brings pleasure to the lowly and obscure, and at the same time is indispensable in the gardens of the affluent. Indispensable it is, if such may be said of any plant, for there would be something distinctly wanting in the greenhouse and conservatory were the time-honoured Fuchsia absent. Under whatever condition it is equally accommodating, and one of the most pleasant natural features of the Isle of Man is the hedges of wild Fuchsias, though it is a difficult matter to convince the average Lancashire "tripper" that they are really of the same family of plants which figure so conspicuously in his little greenhouse at home. As climbers for pillars and rafters we have Avalanche and others of similar type, and for the herbaceous border there are Fuchsias coccinea, virgata, gracilis, and many another that give beauty during the summer months, and require no further protection in the winter than a covering of litter to exclude severe frost.

It is, however, amongst the florists' varieties that we have the Fuchsia in its most pleasing aspects, and at the present time plants that have been resting through the winter are pushing their young growths and propagating is going forward. For the adornment of corridors and large conservatories old plants are extremely useful, and as growth is now commencing potting should be proceeded with. Branches should be thinned and trimmed, the idea being to train the plants in pyramidal form, and later if a succession is needed a portion of the plants may be removed to a somewhat shaded position outdoors and brought in as required, by which means a fine display of specimen plants may be kept up throughout the season. Light and air are conducive to sturdy growth, and when the pots are full of roots applications of liquid or chemical manure may be given with advantage. Soot is a capital fertiliser, as it gives sturdiness to the foliage.

Plants for all purposes may be now raised from sturdy cuttings taken from the old stock. Small well-flowered examples in 5-inch pots are well suited for table decorations, and larger specimens may be grown for the conservatory or exhibition purposes. The routine of propagation is so simple and well known that there is no necessity to go over the old ground again. Abundance of light to keep the young plants short jointed is the chief requisite, and not allowing them to become too pot-bound before shifting to larger receptacles. The principal training required is to place a stake to the main stem, not stopping the leading shoot, but pinching back the side growths, in order to insure a compact habited plant. If late flowering plants are required it is advisable to remove a portion to the shelter of a cold frame. Fuchsias are not commonly subject to attacks from insect pests, red spider being the worst, and this may be kept in check by frequent syringing.

Since the revolution in the old stereotyped system of bedding, and graceful effect has taken the place of stiffness and formality, the Fuchsia

plays no small part in the adornment of the flower garden in summer. To see them in perfection one should pay a visit to one of the public parks, where they are largely used. There the graceful habit is shown to great advantage, and one is rather surprised that they are not more largely grown for this purpose in private gardens. If planted in beds with a groundwork of Violas or other dwarf-growing plants nothing could be more effective, the chief care being to pinch off the seed pods as the flowers fade in order to insure continual blooming. Then, again, as single specimens for planting here and there in the turf they are admirable, and for this purpose they are often allowed to remain in the pots, the latter being sunk into the ground and the turf replaced round the stems.

Such are the uses of the old-fashioned Fuchsia, and where have we another plant so generally accommodating? Varieties are numerous, and one has only to run the eye down the lists given in florists' catalogues to notice sorts that have been in cultivation for years, and also others of more recent introduction. Another doubt arises as to whether as much care is taken over the cultivation of the plants as was once the case. In the days of trained Azaleas, Heaths, and other specimen plants pyramid Fuchsias were a feature at many of the leading shows. Granted that utility has to a great extent taken the place of formality, is this sufficient reason that the growing and exhibiting of specimen Fuchsias should be given up, for not are they only monuments of horticultural skill, but in every respect graceful and artistic? At the great summer exhibition at York there are always to be seen fine plants, and with this exception I do not remember having seen anything out of the ordinary during recent years.

Perhaps the Fuchsia has become to be looked upon by the gardener as only an amateur's plant, and not worthy of the superior skill of the former. If so, the sooner such an idea is banished the better, for long service has proved its worth, and no occupant of the greenhouse gives better returns for care on part of the cultivator. But I have said enough; I only intended to remind, and in the rush for the new let us fully realise the usefulness, beauty, and utility of the old.—H. H.

BRIEF NOTES ON ALPINE FLOWERS.

HEPATICAS.

WE have had references to these old-fashioned flowers both in an interesting article by "R. P. B." and in "Hardy Flower Notes." A catalogue which has just come to hand contains a wonderfully varied list of these flowers, which may interest others in addition to the correspondents who have written of them. *Acutiloba*, *angulosa*, and *angulosa* major are offered. Then there are the deep purple blue H. Barlowi, the common single blue and red, and the European form of the single white. Of double forms there are two blue ones, marked "No. 1" and "No. 2," and the double red. There are also the North American single white, one named *alba cœrulea*, described as white, delicately tinged with blue; *alba major*, large single white; *alba rosea*, white, tinged with pale rose, lovely.

Then we have one named *triloba* "Beauty," which from the description one would think would answer to "R. P. B.'s" "argentrive" or ash-coloured one. It is said to have silvery grey flowers and marbled leaves. This is followed by *triloba cœrulea*, which we are told is quite distinct from the single blue European form with its variety *pallida* "pale cœrulean blue." This, again, has a major form with larger flowers. We are also offered *cœrulea purpurea*, pale blue tinged with red. Lilacs are also included as we see from *triloba lilacina* with "lilac" flowers, and *lilacina pallida*, pale lilac. *Rosea delicata*, very pale blush shading to white; *rosea pallida*, pale rose; and *rosea splendens*, bright rosy crimson, conclude a long list which must include flowers tempting to fanciers of these old-fashioned and bright plants. Possibly enough there may be very little difference between some of the shades. The plants are offered by a reputable nursery which, to my knowledge, has an almost unique stock of alpine flowers. It is not my duty, however, to name the place. The advertising columns of the Journal are the proper medium for the owner, but a recital of the varieties to be obtained in commerce may be of value to some.

SAXIFRAGA BURSERIANA.

The ordinary form of *Saxifraga Burseriana* is now in flower, and very pretty it is with its spiny tufts of grey foliage surmounted by the crimson buds or white flowers visible at this season. It is unfortunate that it is not easily grown into large masses on account of its liability to die off on becoming a plant only a few inches across. It may be kept a little longer, and may be grown into a larger plant by mixing a little peaty soil and sand together and working them carefully among the rosettes of the plant immediately after it has flowered. It is well, though, to propagate fresh plants occasionally. This may be done by taking off small pieces and planting them by themselves on the rockery, or by placing them in pots of sandy peat surfaced with sand, which can be put in a frame or cold greenhouse. The varieties of this pretty little *Saxifraga* tend to increase, as besides the ordinary form there are two varieties passing under the name of *S. Burseriana* major, and seed is now offered as *S. B. biflora*. I have seen nothing of the last, so cannot say anything about its merits.

SOLDANELLAS.

Some of the *Soldanellas* do not flower well unless covered with glass from about October to February, or March; but now that the flower

stems are showing well above the plants the glass may be removed. These little plants like a rather moist position in peaty soil. They are not very often seen in gardens, but usually please everyone with their pretty bell-like fringed flowers. The *Soldanellas* are quite hardy and will flower among the snow, but the glass seems to be needed to induce them to flower. Our comparatively sunless winters appear to be unfavourable to their flowering.

CROCUS BIFLORUS ARGENTEUS.

Are there many who know this variety of the "Scotch" Crocus? I question if there are. It is described as "snow white," and nothing can be nearer in the way of telling in words the peculiar white of the flower. There seems just a sufficient addition of a tincture of blue to give the blooms the glittering coldness of look given by snow. Not that one is affected the same way as if we looked on a cold-giving material, but it is almost marvellous how nearly the effect of snow is produced without the actual sensation. Then the effect is heightened by the bright orange colour of the anthers and stigmata, and it is possibly the warm colour of these which deprives the flowers of the coldness of their snow-like petals. The ordinary *C. biflorus* looks almost ivory-white when placed beside *C. biflorus argenteus*.

HARDY CYCLAMENS.

Judging from the columns of the gardening press, the hardy Sowbreads are likely to be a little better appreciated than hitherto. In "Brief Notes" one cannot enter into much detail about them, but a few lines may with advantage be devoted to mentioning the few really hardy species. The earliest of these is *C. Coum*, a long known little species with round leaves and small crimson or white flowers. The next is *C. Atkinsi*, which, for anything definitely known about it, may either be descended from *C. Coum*, or be a hybrid of that species and *C. ibericum*. It may be had in various shades of red or white. Both of these flower very early. Coming in July, or at times later, is *C. europæum*, another little round-leaved species, varying from pink to carmine. This does not usually do so well in British gardens, and probably wants a little more shade than it generally receives.

Then comes *C. neapolitanum*, whose flowers come before the leaves, and are also of various shades. The leaves of this are very prettily marbled, and are very ornamental all through winter. It is quite hardy, but, like the others, prefers some shade. Young plants, or plants in pots, are the best to purchase, and the crown of the tuber ought to be put an inch or, better still, 2 or 3 inches below the surface. A rather free soil is better than a stiff one, and some plant with success in grass under deciduous trees.—ALPINUS.

THE DAISY PEA.

THE provision of a constant supply of Peas of the best quality throughout the summer months is an item of work with which every gardener has to reckon. It sounds a comparatively easy thing to do with the dozens of excellent varieties now in commerce, and from which the grower has to make a selection. As a matter of fact, there are far too many Peas, some of them introduced as distinct fixed novelties, which are only selections from old ones, that after a season revert to the parental type. It would be advantageous if the list were curtailed, and no matter how hard it had to be compressed Daisy would of necessity remain.

It is beyond a doubt one of the finest dwarf early Marrowfat Peas in cultivation, and it is one that ought to be grown in every garden whose owner appreciates Peas. Sturdy and branching habit, requiring no stakes, coming early and remaining late in profitable productiveness, giving green peas of considerable size and of best quality, it is one of the very front rank. Like many other splendid Peas, it was put on the market by Messrs. J. Carter & Co. of High Holborn, to whom we are indebted for the photographic illustration given in fig. 48.

WINTER FLOWERS AT DE WALDEN HOUSE.

AT this the princely Eastbourne residence of Lady Howard de Walden gardening is carried out in a spirited manner, as this much-respected lady takes great interest in the garden. She is well supported by Mr. J. Simmons, her head gardener, whose ambition seems to be the provision of agreeable surprises in the way of floral displays at all seasons of the year.

Many houses have been recently erected, and a fine spectacle presents itself in the show houses—Primulas, Cyclamens, Cinerarias, Pelargoniums, Azaleas mollis and indica. Lilacs are grown in numbers for this work, and are arranged in groups of about fifty of a kind, intermixed with foliage plants, and is a pleasing and novel display. Good but neglected plants, such as *Strobilanthes* (Goldfussia) *anisophylla*, *Manettia bicolor*, and *Centropogon Lucianus* are well grown. The former, with its lilac flowers, is very pretty. *Manettias* are grown on pyramid-trained frames about a foot high, and are a mass of attractive scarlet and orange flowers—a grand plant for decoration work as seen here. *Centropogon*, with bright rosy scarlet sprays six and seven to the plant, are most graceful and attractive also.

The stove plant houses contain a not over-large, but a clean collection of useful flowering and foliage plants. Conspicuous amongst the former *Anthurium Scherzerianum* is flowering freely, while Palms and well coloured *Dracenas* and *Crotons* are evidences of high-class culture in the

foliage sections. There is also a good collection of hardwooded *Ericas* of all the leading kinds, seldom now grown, but great favourites of her ladyship. Some of them are 3 feet through, and represent all the leading and popular kinds. Azaleas look well, and promise a brilliant show later on.

The various fruit houses show signs of activity. Peaches well in bloom, Vines breaking well. Forced Strawberries are a special feature, and fine crops of forced Beans are noticeable. A plant not often seen is *Sonchus laciniatus*, of a slender *Aralia*-like habit. Several are grown

FIG. 48.—PEA, CARTER'S DAISY.

here, standing upon pots, and are beautiful objects, the lacinated leaves hang gracefully even over the pots. Some of the specimens are fully 2 feet high. The grounds are well kept. Every corner and nook seems to be utilised, and planted with something of interest suitable for the various positions. The same may be said of the walls and fences, the object being to turn everything possible into use for either foliage or flowering plants. The place inside and out is a model of cleanliness, while practical skill is evident in every department, the credit of which is due to Mr. Simmons, who has had the entire charge since the formation of this interesting garden.—URBANUS.

STOCK FOR TREE PÆONY.

THE stock used for Tree Pæony (if stock it can be termed) is generally the root of the common red Pæony (*P. officinalis*). It is usually done in the following way:—A plant is taken up bodily, and all the strong roots are selected, or as many as are required. All the small fibrous roots are preserved. Scions of the tree variety are selected, which should be those which bore no flowers the preceding season if possible, although this is not absolutely necessary. These scions are cut wedge shape. The root is also split, and the scion is thrust in exactly in the same way as an Apple or other trees are grafted.

The root is now placed in a pot sufficiently large to accommodate it comfortably, and plunged in a bottom heat of about 70°. It should be plunged over the union; cocoa-nut fibre refuse is the best material. There are two seasons at which this can be done—viz., August and January. If left till January care should be taken that it is done before the scions start into growth. Of course Mr. Bardney is aware that these plants start very early in the new year. I should, however, recommend August for this work.

A second and a much better way in every respect is layering, but one must have large plants before this can be done, and as these plants are of slow growth one must be prepared to wait for some years before any of the tree varieties can be increased in this way.

I have plants both grafted in the way described and from layers. Those on their own roots are the best in every way. These Tree Pæonies are great favourites in many other gardens, and we are planting many of them of the best kinds; but we must have patience to see them at their best—viz., from 5 to 6 feet high. I saw a plant of a good variety of about this height and as much through in full flower two or three years ago, and it was gorgeous.

The reason the old officinalis is commonly used is owing to its vigour. I trust this will meet Mr. Bardney's desire; he will, however, find the raising of these plants rather tedious work.—T. A.

YOUNG GARDENERS' EXAMINATIONS.

ON page 144 of the *Journal of Horticulture* a letter appears signed "Novice," in which reference is made to our laboratories, and an anxiety expressed for information bearing upon the character of the practical work done in our Essex County School of Horticulture. I have much pleasure in giving your correspondent the following brief particulars.

The school is held in the Biological Laboratory of the Essex County Council, and at present consists of four terms in the year—three being devoted to duplicate elementary courses and one to an advanced course. The elementary courses run three weeks each, while the advanced course is extended to a month. Attached to the laboratory is a greenhouse for demonstration purposes, and a small botanic garden. About ten minutes' walk from the laboratory is a 3-acre garden, for demonstration and individual practice. The students are all scholarship pupils, ranging in age from fourteen to twenty-five, and in almost every case are drawn direct from gardens, this latter condition being the very essence of our system.

The pupils attend a botanical lecture every morning from nine to ten, after which they verify the facts of the lecture from ten to twelve by actual laboratory work with microscopes under the direction and assistance of the lecturer on biology and his demonstrator. From twelve to one is the dinner hour. From one to four the pupils are in greenhouse, potting shed, or garden under the charge of the staff horticulturist, who demonstrates approved methods of culture and superintends the individual work of the pupils. From four to six is tea and recreation. From six to seven the students attend a lecture dealing with the horticultural processes of the afternoon or next day, while from seven to half-past eight is reading and private study under supervision and assistance. The whole course of instruction is intended to impart sound elementary instruction in the best methods of cultural treatment based upon a knowledge of the structure and physiology of plants.

With respect to the "wonder" expressed by "Novice" I certainly think that our students could easily compete with any other young fellows of their own age in actual garden work such as is mentioned by your correspondent. Perhaps "Novice" would like to visit our school and see us at work. We have an elementary course running from March 22nd to April 10th, and should he care to accept this invitation I will be delighted to meet him. I enclose a prospectus and time table of the ensuing spring course.—DAVID HOUSTON, *Staff Biologist, Essex County Council*.

THE YOUNG GARDENERS' DOMAIN.

STREPTOCARPUS.

THIS is one of our most useful greenhouse plants. Some of the new hybrid varieties are exceedingly attractive, also varied in colour, and the plants are of easy culture. They thrive well in a rich compost of loam, leaf soil, and decayed manure, with a little sharp sand added, and like plenty of drainage, as they are not deep-rooting plants.

They should be potted in the early spring and placed in a warm greenhouse, where they soon commence growing and flowering freely, and will continue through the summer months without a break. As the spring advances they require shading, as they are unable to stand hot sun. The free use of the syringe between the pots is also helpful, as they enjoy a damp cool atmosphere. As the summer advances a little feeding is very beneficial, and after the flowering season is over water

should be reduced and the plants kept a little dryer during the winter months.

They can be raised from seeds and increased by division. Seed sown early in February in shallow pans of light soil in a brisk bottom heat will soon germinate. When the seedlings are large enough place them singly in thumb pots filled with light soil, keeping the plants in brisk heat till they become well established, and they will flower by mid-summer.

Their worst enemy is mealy bug, and the leaves being so pubescent it is difficult to get rid of. The best remedy is careful washing with a stiff brush and the application of some approved insecticide, care being taken that the wash is not allowed to run down to the roots. Green fly is also troublesome, but can be got rid of with a little fumigation.—A. C. W., *Balcarres*.

THE CULTURE OF ARUMS.

THESE stately favourites for conservatory decoration or cutting may be treated in various ways, but after several experiments I have found the following method answer best. Potting should be done about the end of August to allow the plants to get established before being housed. I have found 10-inch pots suitable and convenient; these should have one crock for drainage, covered with rough leaves or litter to the extent of about 2 inches. This is quite sufficient, as the plants need a considerable amount of water when established.

Our compost consists of three parts heavy loam with one part horse droppings prepared as for a Mushroom bed, the whole passed through an inch riddle. To this may be added a 5-inch potful of Thomson's Vine manure or Clay's fertiliser to every barrowload of soil. Four crowns are sufficient to fill a 10-inch pot. Any smaller crowns may be placed in 5 or 6-inch pots, and grown to increase the stock should this be required, or to replace any that go wrong by accident or otherwise. They require potting firmly.

Towards the beginning of October place the plants under glass in a night temperature of not less than 45°, or more than 50°, increasing this to an extra 5° in November. This temperature will bring them on to follow Chrysanthemums, and afford spathes to cut for Christmas. The leaves require sponging occasionally to keep down fly, but the plants should not be syringed, as this is apt to discolour the flowers.

Constant feeding must be resorted to as soon as the plants are housed, and liquids are preferable, as they act much quicker than solids. Liquid manure from stables and soot water, with an occasional application of sulphate of ammonia, I have found to give the best results; the sulphate to be used to the extent of about 1 oz. to every 2 gallons of water. Under this treatment a constant supply of splendid spathes can be maintained until the end of April without detriment to the plants. A rest of about six weeks after Christmas gives extra vigour to the plants for Easter flowering.

The early part of May is the best time for turning them out of doors again, planting in a trench with a fair dressing of manure and mulching with rough straw. Keep the roots well watered all the summer, and you will build up strong plants to commence with another autumn. Under this treatment we have at present flowers fully 9 inches across with foliage of a dark green colour. The plants are continually throwing up flowers of the purest white.—GAECON.

THE STRAWBERRY.

(Continued from page 145.)

As the plants are required for forcing choose the earliest varieties and those having the most prominent crowns. Examine the drainage, making it clear if required. Remove all dead leaves, and wash the pots before housing. Some growers advise plunging the plants in a hotbed made of leaves and short litter. This is advisable where practicable, as it causes quicker root action, and the plants are better able to stand hard forcing. Where there is no space at command for plunging them, nor house especially adapted for their culture, shelves in vineries or Peach houses near the glass are suitable. The plants may be taken there as the houses are started, the gradual rise of the temperature for the Vines or trees suiting them very well.

Where a house is set apart especially for Strawberries start with a temperature of 45° to 50° by night and 55° by day. Little water will be required at first; but each pot should be examined every morning, and those requiring water should receive a sufficient supply to pass to the drainage. When the flower spikes show an occasional application of liquid manure aids the plants to develop strong, bold spikes. As the flowers commence opening raise the temperature to 55° by night and 60° by day, ventilating freely, yet judiciously, avoiding draughts. Distribute the pollen either by shaking the flowers or by a camel-hair brush. When fruits have set freely and are swelling, thin to a reasonable number on each plant. Increase the temperature to 60° by night and 65° to 70° by day, admitting air on all favourable occasions, closing the house early. Syringe freely, and afford liquid manure until the fruits colour.

Should mildew appear dust the leaves with sulphur. Green fly or thrips may be eradicated by fumigation. When the fruit commences colouring cease the liquid manure and gradually decrease the supply of water. At the same time admit more air, as if grown close the fruit would be flavourless. Those colouring in vineries or Peach houses which are being forced should be taken to a more airy place for the same reason. When nearly ripe abundance of air should be given, and very little water will be required. Do not allow them to lose colour before gathering. Good results may be obtained from the following varieties:—La Grosse Sucrée, John Ruskin, Royal Sovereign, President, Auguste Nicaise, Lucas, and Waterloo.—SEMPER.

ADIANTUM CUNEATUM.

ONE of the most useful foliage plants is, I think, the Maidenhair Fern (*Adiantum cuneatum*). Whether they are used in combination with other plants, or in a house devoted entirely to them, they afford a pleasing effect. Their delicate fronds in their developing or mature state demands our admiration. Valuable as they are for the above purposes, they are equally useful for vase and buttonhole work, an advantage beyond many others. What flower is not enhanced in beauty by the addition of one of their fronds? The plants are very useful for placing round the base of large Palms for house decoration; a large number being grown exclusively for this purpose, varying in size according to size of Palm. They also add to the beauty of deciduous Orchids, such as *Calanthes*, when intermixed with them.

The culture of the *Adiantum cuneatum* is comparatively easy, provided we have healthy plants to start with. The most important item I have noticed with them is that they object to being overpotted, and, considering they benefit by an occasional watering with liquid manure; overpotting should be guarded against. They prefer clean to dirty pots, effectively drained with potsherds and charcoal. It is a good plan to place a piece of perforated zinc over the hole before placing in the crocks, as this prevents woodlice and slugs—two of the worst enemies of this Fern—from hiding among the drainage till a favourable opportunity offers for them to feed on the tender fronds.

The compost we find the most suitable is a mixture of good fibry loam and well-decayed leaf mould in equal parts, with a moderate addition of sand. The soil should be made firm, as this tends to make the fronds more hardy, thus causing them to last longer, especially after being picked. The pots should not be filled too full, judgment determining this according to size of pot, as they require copious supplies of water while growing.

In the case of increasing stock we find it best to employ sporelings, as by cutting through old stools the roots are often very much injured, and sometimes they are entirely destroyed on the cut side. This often causes the plant to grow and increase on one side only, which looks very unsightly.—ASPIRANT.

HARDY FRUIT GARDEN.

Strawberries.—*Young Plantations.*—Quarters of young plants established early or late in the previous autumn will now be benefited by stirring the soil between the rows of plants. In soil of a stiff retentive character, or any that has become more or less consolidated owing to the wet, the loosening will be best done with a fork. Where a Dutch hoe will pass readily through the soil this is the best implement, because the soil does not necessarily require moving deeply, especially near the plants. The object of hoeing is to destroy and keep down weeds. Further than this, a loose, shallow, open surface is very beneficial to young plants as it accelerates their growth, inasmuch as the soil is warmed and the oxygen of the air admitted. The crumbly layer of dry soil thus formed also prevents rapid evaporation of moisture, a matter of importance in a dry spring and early summer. In a wet season, too, hoeing is of advantage during the dry periods which may follow the moist—that is, when the soil becomes caked on the surface. Any plants that have become loosened during the winter should be made firm.

Old Plantations.—If a manurial mulch were not applied to these in autumn a dressing now is really desirable for enriching the soil and strengthening the growth. A dressing of soot may first be given, scattering it round the plants, not actually over the crowns. A peck of soot to a rod will both be useful as a manure and as a destroyer of slugs, which invariably lurk about the crowns of the plants. In all cases strong weeds should be forked out. These include Dandelions, Docks, Couch Grass, Nettles, and Bindweed, all of which have perennial roots, and though the tops may be cut down further growth is soon made. Annual weeds, as groundsel and chickweed, are soon destroyed in dry weather after being cut down.

The manure applied must be rich and moist decomposed farmyard manure. Strawberries well manured in autumn with similar material do not require a mulching of the same character now, but one of fresh littery manure. The solid parts of this afford some nutriment, and the straw or litter becomes bleached or washed, by which a clean bed is secured for the fruit to rest upon when ripe.

Applying Artificial Manures.—It is only old or established beds in bearing that need assistance with chemical or artificial manures. With young plants stimulating manures are more likely to cause superabundant growth of foliage when the plants are not in bearing to check this disposition. A mixture of artificials, comprising important elements of plant food likely to be deficient in the soil, are the most advantageous. Nitrogen, phosphoric acid, and potash are usually required to be added oftener than other elements also essential, but generally present in all fertile soils. A fertiliser compounded of the following is good for Strawberries requiring additional help:—2 lbs. each nitrate of soda, sulphate of ammonia, and potash, with 4 lbs.

mineral phosphate. This would be sufficient for a rod of ground. Crush the salts quite fine, and mix the whole compound with some dry earth. This will insure the mixture being distributed evenly. Nitrate of soda alone is a useful manure in spring for Strawberries, because it affords direct and special food to plants at a time when they find difficulty in obtaining it from the soil owing to the conditions for supplying nitrogen in the form of nitrates not being sufficiently present in the soil at this season. Nitrate of soda, crushed very fine and mixed with soil, may be applied at the rate of 1½ to 2 lbs. per rod.

New Plantations.—Plants placed in nursery beds in autumn to form more roots and increase in size before finally planting may now be transferred to permanent quarters. The winter season has afforded an opportunity to prepare the soil thoroughly. Strawberries require rich, deep, firm soil. Before planting the essential conditions for encouraging free strong growth should be studied, adopting the best means for improving the soil in order that it may remain in fairly good heart for at least three years, the usual period Strawberries remain profitable. They succeed well if planted on freshly dug and manured ground, but it is advisable on light soils to firm the ground well before planting, selecting a dry period for the work of compression, which may be carried out by treading or rolling.

Plants from nursery beds ought to be carefully lifted with as much soil adhering to the roots as possible, and placed a little deeper in the ground than before. Avoid crushing the tips of fibrous roots into holes too small, but place so that they may be able to extend freely. More care, however, is required with plants having no adhering soil. The roots should be spread out on little mounds of soil, carefully covering with fine material spread over them from the crowns outwards. Press the soil firmly and equally about them when the roots are covered, levelling the remaining soil with the spade.

The distance between the rows of plants is governed by the habit of the variety planted. Strong growers, like Sir J. Paxton, James Veitch, and Noble, need the rows to be 30 inches apart, the plants 20 to 22 inches asunder in the rows. Two feet between the rows is the best distance for the majority of varieties of medium growth, the plants 18 inches asunder. Smaller growers of the type of Vicomtesse Hericart de Thury may be 15 inches from plant to plant in the rows, the latter 2 feet asunder, which is more convenient than narrower rows.

FRUIT FORCING.

Peaches and Nectarines.—*Earliest Forced House.*—Where Alexander or Waterloo, Early Beatrice and Early Louise Peaches, with Cardinal and Early Rivers Nectarines are grown, either in pots or planted out, the fruit will soon have completed the stoning, and will advance rapidly to ripening if duly supplied with nourishment and the trees are not overburdened with fruit. This swells and ripens under the same conditions as are required by the older second early and midseason varieties whilst stoning. The temperature then requires to be kept as equable as possible, too much heat at night being unfavourable to the fruit, and cold draughts in the daytime often giving a check that causes it to fall. This must be avoided by judicious early ventilation made up for by closing early in the afternoon; but cutting winds are so pernicious as to bring off the fruit wholesale, and drying the atmosphere by over-fumigation is equally disastrous. Continue the temperature at 60° to 65° at night and 70° to 75° through the day, syringing morning and afternoon to keep red spider in subjection, but promptly eradicate it by an insecticide if it gains a footing. Thin the fruit directly the stoning is effected to the number required for the crop. It is not wise to let the trees stone twice as many fruit as are required, and it often happens that leaving too many brings off the major portion. One fruit to a foot of trellis is ample for the large-fruited varieties; medium-sized fruited sorts and Nectarines may be left a little closer. Tie the shoots to the trellis as they advance, and stop any growing too long at 12 to 15 inches, pinching laterals to one leaf, and, above all things, avoid overcrowding. Shoots retained to attract the sap to the fruit should be closely pinched to one leaf unless the trees are weak and it is desirable to encourage root action by a little extension, yet do not allow more growth than there is room for.

Succession Houses.—Disbudding and tying-in must be attended to before the shoots become too long, disbudding gradually. If the blossoms have set thickly—more than a dozen on a length of 1 foot of shoot—thin them soon after the remainder of the blossoms are cast, removing the smallest fruits, those on the under side of the branches and the badly placed, leaving about three of the best. These in turn should be reduced to two or one when the size of marbles, or not later than as large as Walnuts. The temperature may be raised to 55° to 60° at night, and 60° to 65° by day from fire heat, ventilating from 65°, and insuring 75° from sun heat, closing moderately early in the afternoon, but avoid a close atmosphere.

Late Houses.—With the buds swelling a light syringing occasionally may be indulged in until the stamens appear, when the floors and borders may be damped instead in the morning and afternoon, leaving a little air on constantly, and employing fire heat only to exclude frost. After the flowers open maintain a night temperature of 40° to 45°, 50° by day in dull weather, 5° more when mild, with a free circulation of air, advancing to 65° with sun. Where the blossom is superabundant it will be advisable, especially in the case of weakly trees, to remove the flowers from the under side or back of the shoots, as the trees may be against front or back trellises. The borders must not lack moisture, affording thorough supplies where needed, repeating, if necessary, so as to bring them into a thoroughly moist state, but avoid making the soil sodden.

Vines.—Eyes.—When those inserted as advised are well rooted they should be potted singly, or, if inserted in small pots, shifted into 6-inch pots as soon as the roots reach the sides of the smaller, placing them on shelves over the hot-water pipes. Syringe well amongst them, and pinch laterals at the first leaf, unless they are intended to be planted out this season and not fruited the next, when the laterals may be left entire, but in that case the Vines must be planted before the roots become matted.

Cut-back.—For fruiting in pots next season these Vines will now be fit for shaking out and repotting, or if that has already been done, and the roots have reached the sides of the pots, they will need shifting into the fruiting, 12-inch, pots. If they have been given bottom heat they should be returned to it for a time, 75° to 80° being sufficient, otherwise bottom heat is not necessary, yet the pots are better stood on slates over hot-water pipes than on a cool bottom. Keep the house close and moderately moist until they become established. Train the canes near the glass, pinching the laterals to one leaf, and thus secure solidified and plump buds. Use clean pots and efficient drainage. Turfy loam with a fifth of old mortar rubbish answers well for potting, but a pint each of steamed bonemeal and soot, and double quantity of wood ashes may be mixed with every bushel of soil.

Earliest in Pots.—Canes started last November have the Grapes in the last stages of swelling, and must be adequately supported with liquid manure and rich dressing, while if the roots extend beyond the pots feed them there as well as in the pots. The very early varieties, such as White Frontignan, Foster's Seedling, Black Hamburgh, and Madresfield Court, are well advanced towards ripening, and will need clean tepid water after the colour is well pronounced. A circulation of warm moderately dry air conduces to the colour and flavour of the fruit, but the Vines must not lack the needful supplies of water to keep the foliage fresh, or the atmosphere be allowed to become so parched as to invite red spider, for the Grapes require some little time to mature after being apparently ripe, and a moderate amount of atmospheric moisture without stagnation is essential to their remaining plump and fresh until cut.

Early Houses.—Vines started early in December and previously forced will have the Grapes stoned, and should have copious supplies of liquid manure or a top-dressing of an approved fertiliser washed in. A light mulching of lumpy, partially decayed manure may be placed on the border, as the Grapes swell considerably in the later stages, even after commencing to colour, and allow a little lateral extension, as every leaf encourages root action, and that leaf duly exposed to light and air aids the Grapes in swelling and finishing. The Vines started later in the year, and of which the berries have been thinned, will need liquid manure applied to inside borders; but surface dressings are more potent in accelerating and keeping surface roots, and a good handful of almost any of the advertised fertilisers per square yard makes a wonderful difference in the colour of the foliage, which means ultimately good colour and high finish in the Grapes. Ventilation needs to be carefully attended to, as with sharp winds and bright gleams of sun the temperature is subject to sudden alternations, which must be avoided by admitting air in small quantities at a time, always in advance of rather than after a great rise of temperature, taking care to allow a good rise from sun heat after closing early in the afternoon at 80° to 85°, allowing the temperature to fall to 65° at night, or even 60° when very cold.

Vines started in January and not forced before have pushed slowly, and some that have started freely show a tendency in the bunches to twist and curl, whilst others are "blind." This may be a consequence of unripe wood and imperfectly formed embryonic bunches. Nothing can be done in such cases, but a slight increase of temperature and a reduced supply of moisture may be beneficial. Avoid the close-stopping system until every part of the trellis is well covered with foliage, then allow no more than there is room for. Vines started with the year will be in flower, and should have a rather drier atmosphere with a gentle circulation of air and a temperature of 65° to 70° at night and 70° to 75° in the daytime, with 10° to 15° rise from sun heat, maintaining moderate moisture by damping the house two or three times a day in bright weather. Muscats should have at least 5° higher temperature, and the flowers must be carefully fertilised.

Succession Houses.—Disbud and secure the growths as they advance, stopping them two joints beyond the bunches where the space is limited, but where there is room allow a greater extension of the shoots before stopping them. Remove the laterals from the joints below the show for fruit, except from the two base leaves, stopping those at the first leaf and to one afterwards as produced. The laterals above the fruit may be allowed to make such growth as can have full exposure to light without crowding, and then be stopped, keeping them pinched afterwards as in the case of those not having room for extension. Remove all superfluous and ill-formed bunches of the free-setting varieties as soon as those that are the most promising for the crop can be selected. Maintain the borders in a proper state of moisture, and secure a genial atmosphere by damping the house well at closing time as well as in the morning and evening. A temperature of 60° to 65° at night is suitable after the Vines come into leaf, allowing 65° to 70° on dull days and 75° to 80° with sun and ventilation, taking care to ventilate early, to avoid cold draughts, and to close early.

Late Houses.—Vines to afford ripe Grapes in August onwards must be started, and Muscats, with other varieties, should be encouraged to move, as the fruit keeps much better when ripened in August or early in September than when the season is more advanced at the ripening period. Vines which have only been recently pruned should be given a little rest before starting them, yet all thick-skinned varieties should

be started not later than early in April, for they take a long time to ripen properly for keeping, and should be assisted all along with fire heat, as upon their thorough ripening depends the Grapes keeping sound. Inside borders may be brought into a thorough state of moisture by the application of water, and if followed by an application of rather thick, but not too strong, liquid manure, it will excite root activity as well as nourish the Vines. Outside borders will only need a little partially decayed manure as a mulch to protect the roots from chill by frost or snow. The atmosphere must be kept genial, sprinkling the rods and every surface about the house two or three times a day, maintaining a temperature of 50° at night or 55° when mild, and 65° by day with sun. Late Hamburgh houses may be kept cool, not starting the Vines until next month—indeed, they may be allowed to push naturally. It will suffice if they have the fruit set by early in June, and the Grapes are ripe in September.

THE BEE-KEEPER.

SEASONABLE NOTES.

THE weather, which is an important factor in connection with the pastime of bee-keeping, has been very changeable since the commencement of the new year. During the early days of February there was a deluge of rain, followed by a few bright days, which allowed the bees to have a good cleansing flight. Then more snow and rain, accompanied by high winds, which have continued with more or less severity to the present time.

The temperature has not been extremely low, as on no occasion was there more than 10° of frost registered. The bees, however, derived great benefit from the few sunny days; but as the ground was covered with snow on two or three occasions many bees were lost owing to alighting on the snow and becoming chilled. The mischief arising from this cause has not been so serious as in some previous years. It is an advantage to shade the entrance of hives during spells of bright sunshine in early spring when the ground is covered with snow. The bees will then remain in their hives instead of being tempted out in their thousands, many of them never to return again.

The genial weather enabled the bee-keeper to make a partial overhaul of his stocks, and in doing so several instances were found of the penetrating power of snow. If there is a weak place in the roof or sides of hive which to all appearance is rain proof, if examined after a heavy snowstorm the interior of the hive and floor-board will be often found to be saturated; but if the snow is cleared off the hive before it thaws there will be less danger of its penetrating through the crevices.

In my own apiary several of the floor-boards were damp, these were replaced with dry boards, which shows the advantage of having loose floor boards, by the ready manner in which they may be removed without disturbing the bees, as at this season there is always an accumulation of dirt from the cappings which the bees are unable to remove during the winter months, and if allowed to remain in the hive will cause the floor to become damp and mouldy. The wax moth, too, which is so detrimental to combs, will breed in the *débris*.

QUEENLESSNESS.

At this season more than any other stocks are often found without a queen. This arises from a variety of causes, but the chief one is in having old worn out queens. During the past few days I have been consulted as to the loss of four colonies by as many bee-keepers, and in each case I am convinced the above was the cause. In two instances the bees were in straw skeps, and had been first swarms for two years in succession. Young queens had not been raised or introduced. The old queen having become decrepit and worn out from old age would in all probability be turned out of the hive by the workers when it was too late to raise a young queen. The bees remaining in the hive would rapidly dwindle away, and the first spell of severe weather would kill them.

The winter is then blamed for the mishap, whereas it was the management that was at fault. The other case that came under my notice was somewhat different, although the cause and result were the same. The bees in this instance were kept in frame hives, which had not swarmed for two years owing to extra space being provided for them in working sections. Had young queens been given to them after the removal of sections in the autumn they would now without doubt have been strong prosperous colonies, as they were well provided with stores. This is a fact that should be constantly kept in mind by bee-keepers—the necessity of raising young queens, as in a general way it is not wise to keep queens after they are two years old. The old queen may be removed and a young one introduced at any time except midwinter, as advocated.

in these pages. It being such a simple matter, and not nearly so difficult as many people imagine, it should not be neglected.

UNITING WEAK COLONIES.

Stocks that are queenless and the workers still alive should be united to other colonies without delay. If the two stocks are separated several yards apart remove them a few feet nearer each other every day the bees are on the wing. On the evening of the day in which the bees are brought into close proximity remove all empty frames from the hive containing the queen, separate the other combs, and sprinkle the bees with flour. Go through the same process with the queenless colony, and place the frames with the adhering bees alternately with those in the other hive, cover them up warm, and if short of stores a bottle of warm syrup may be given to them, and success will follow, as the colony will be strengthened by the added bees. The entrance should be reduced to half an inch; this will prevent robbers from gaining an entrance.

It is quite easy for one who is used to bees to tell if the stock is queenless by observing them when the sun is shining in the middle of the day at this season. In those hives that have an active fertile queen the bees will be seen darting in all directions in search of pollen, but those having no queen will remain about the entrance to their hive in a languid kind of manner. When this is observed steps should at once be taken to examine the stock, and if the queen cannot be found treat them as advised above. Robbers, too, will soon find out those stocks in which the bees are dead or so weak that they cannot protect themselves against intruders.—AN ENGLISH BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Cooper, Taber & Co., Ltd., 90, Southwark Street.—*Wholesale List of Farm Seeds*.
E. P. Dixon & Sons, Hull.—*Farm Seeds*.
Ellwanger & Barry, Mount Rose Nurseries, Rochester, N.Y.—*General Catalogue*.
Kent & Brydon, Darlington.—*Farm Seeds*.

* All correspondence relating to editorial matters should be directed to "THE EDITOR." Letters addressed personally to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post.

Mustard and Cress in Punnets (H. H. S.).—The Mustard and Cress as sold in punnets in London is not "produced" in them, but grown in houses and frames according to the season of the year, and packed in the punnets quickly and neatly as the produce is cut. No doubt it could be grown in punnets, but would not be likely to pay so well as by the ordinary routine.

Caterpillar Found in Garden (H. L.).—The "caterpillar" is the larva of a beetle belonging to the family Telephoridae, and evidently a "soldier" or red coloured species, probably *Telephorus lividus*, but the "soldiers" and "sailors"—the red and blue—are difficult to distinguish in the larval state. It is carnivorous in mode of life, and does little, if any, harm to vegetation.

Insect Eating Maidenhair Ferns (W. P.).—The insect is the grooved or black vine weevil (*Otiorynchus sulcatus*), and very fine specimens they were, and we soon passed them into oblivion. They are absolutely vegetable feeders, both in the grub and beetle stages, the former feeding on the roots of various plants, being very fond of the fleshy young roots of Vines and Peaches, and, above all things, like the fleshy corms of Cyclamen. Indeed, we do not know what form of root the grubs will not eat that are of a sound sustaining nature. The weevils are very partial to the rising fronds of Adiantums, Vine and Peach leaves, eating holes in the latter, and doing an immense amount of mischief. The best means of riddance is to capture the beetles, looking for them after dark with a lantern, proceeding cautiously, and not forgetting to examine the surface of the soil carefully. On Vines place sheets on the soil in the daytime beneath the Vines, enter the house very cautiously after dark with a shaded lantern, shake the Vines or trees sharply, turn on the light, and collect the skulking beetles into an old tin containing a little petroleum.

Senecio macroglossus (Juvenile).—The Ivy-leaved Senecio is one of the most useful of winter-blooming plants. Winter-flowering plants which will do well on the roofs of greenhouses are not so numerous that so useful a one as this should be neglected. The flowers resemble those of the beautiful and popular yellow Marguerite, *Chrysanthemum Etoile d'Or*, but are of a somewhat lighter yellow or creamy hue. They are produced very freely, and at a time of the year when greenhouse flowers are scarce; hence they are doubly valuable. The leaves, how-

FIG. 49.—SENECIO MACROGLOSSUS.

ever, are as attractive as the blossoms, bright and cheerful as the latter are. They closely resemble those of the small-leaved Ivies; in fact, are difficult to distinguish from them, and are highly ornamental. The plant does best when planted out and trained up the roof of a house; but may also be well grown in a pot. In either case good drainage should be provided, and a compost of light sandy loam with a little leaf soil will be suitable. *Senecio macroglossus* has been neglected too long. Flowers and leaves are represented by the engraving, fig. 49.

Planting Flower Beds (Kewhurst).—The Gladiolus and Asters would not make a good display till late in the season, so they may be put out of our calculations. But among the other plants you name there is plenty of material for making a very effective bed, if disposed in the following manner. Plant in the centre a Cactus Dahlia and two others on each side at a distance of 3 feet from it, so as to form a line running lengthwise with the bed. Next place a string line along the entire length of bed 18 inches from the edge, and opposite each opening between the Dahlias plant three strong clumps of perennial Lobelias in the form of a triangle, two clumps on the inner and one on the outer side of the line. Repeat the operation on the opposite side, then plant a row of Antirrhinums all round the bed, 9 inches from the edge, and fill in the whole of the remaining space with Brompton Stocks. In suggesting this arrangement I presume the Antirrhinums are the dwarf bedding kinds. Should they be the tall growing ones, reverse the position of Stocks and Antirrhinums. In each case an edging of *Pyrethrum laciniatum* will give the bed a finished appearance. It is not yet too late to sow seed to produce the necessary plants for this purpose.

Cinerarias Dying Off (H. B.).—There are many causes of the seedlings dying off when from six to eight weeks old from the seed, the chief being a form of mould, which attacks the plants at the collar, and can only be avoided by keeping them moderately thin, so that air can play freely about them, and being careful not to overwater or keep too close, using shading only to prevent flagging and scorching. The fungus is usually present in the leaf mould, being developed from a sclerotium, and is named *Botrytis cinerea sclerotiphila*, the black sclerotium being once called *Sclerotium durum*; but it is the conidial stage of *Sclerotinia sclerotiorum* (Mass.). It gets hold of the plants because they are potted too deeply, damp setting in and rendering its work easy. In what you mean to sterilise the soil does not appear. We suppose either by treating with boiling water or subjecting to heat. If the latter it is as well not to char it, especially if leaf soil, as that takes most of the nature out of it. The treatment of the loam is a "caution," as you have used the exact proportions bricklayers do in making mortar,

the lime being over 33 per cent. Ten per cent. is a maximum quantity to use, and even then the lime must be the best chalk lime, and the compost allowed to lie for about three months. Of course you can make the percentage what you like by adding loam and leaf mould when preparing the compost, but unless the added ingredients are sterilised what will be the good of the lime treatment? To the heap we should now add eight parts loam, and the leaf mould you intend to use, incorporating thoroughly and leaving till the time required for potting. This will give a good blending of the ingredients, and no doubt form a suitable compost.

Vine Leaves Scorched (*Ignoramus*).—There is no fungoid disease or micro-organism either on or in the tissues, but a slight form of scorching—at least, it appears as such—which is probably owing to the extremely thin texture of the leaves and their sudden exposure to a cold current of air. The growths are very weak, and certainly would have been better for a freer amount of air, especially in the early part of the day. Besides, they appear unfruitful. Could you not improve the condition of the Vines by a judicious use of fertilisers?

Propagating Ficus elastica (*J. J.*).—This extremely useful decorative plant is easily increased by cuttings or eyes having a leaf attached, inserting the cuttings or eyes singly in small pots in sandy loam with a little leaf soil added, letting the base of the cutting rest on a little silver sand and filling the hole with the same, eyes being placed about an inch in the soil. Place in a close frame in a propagating house or one with a stove heat, and keep close, moist, and, if need be, shaded until rooted, then gradually inure to the air of the house and grow on, shifting into larger pots as required; but this plant does not require a large amount of root space, or rather the smaller the pots the more useful the plants as a rule for decorative purposes, very fine plants being had in 6-inch pots or less.

Tomato Troubles (*S. J. A.*).—We have, in accordance with established practice, read your letter, addressed to Mr. Iggulden at this office. It shall be sent to him, and he can answer it privately if he likes (a stamped directed envelope is not enclosed)—not through our columns, as it was not addressed to the Editor; and both his and your attention may be drawn to our desire, published at the head of this column. We note that "a heavy dressing of quicklime" acted with decided benefit against black stripe in one house, and not in another; but where it failed, "it was found on digging in the autumn that it had not been mixed with the soil, but formed a solid layer where it had been dug-in." It is justly due to Mr. Abbey that he be made aware of the manner in which some of his advice is carried out. After inspecting hundreds of thousands of Tomato plants, we are more than ever satisfied that the sounder the principles of cultivation and the more carefully the necessary details in routine are carried out, the greater the immunity of the plants against destruction by their enemies, and we shall be a little surprised if Mr. Iggulden dissents very strongly from this view of the case. If he does it will not alter our opinion.

Ground Infested with Slugs and Snails (*Gardener*).—When land is thoroughly infested with these pests, "so bad indeed that such seedlings as Seakale, Scorzonera, and Onions never come through, as they are all eaten off in the ground," it is difficult to effect a clearance. The best procedure is to give the land a dressing of lime, $1\frac{1}{4}$ cwt. per rod ($30\frac{1}{4}$ square yards), placing the freshly burned best chalk or land lime in small heaps convenient for spreading, slaking, using only just sufficient water to cause it to fall to a fine apparently dry powder, and whilst hot spreading evenly on the surface, pointing in with a fork as soon afterwards as possible, and taking small spits so as to mix evenly. It is best done in a dry time, or when the ground is in good working order, with a prospect of fine weather. The ground need not be stirred deeper than 6 inches, as the lime will get down fast enough. This will permanently improve the land, especially of an old garden or of a heavy nature, and do much towards freeing it of the slugs. In addition to the lime dressing, or if not convenient to use it, which, however, we strongly advise, you may employ the following mixture:—Bone superphosphate, dry and crumbling, $3\frac{1}{2}$ lbs.; kainit, best quality, $3\frac{1}{2}$ lbs.; nitrate of soda, 95 per cent., $1\frac{1}{4}$ lb., mixed, per rod ($30\frac{1}{4}$ square yards), which will give excellent results both as a grub killer, slugicide, and manure; but remember this is a maximum dressing, and meant only for bad cases. It should be applied a few days in advance of sowing or planting, and must not be more than lightly pointed in. We have found it an excellent practice to cover the seed in the drills with wood ashes in a moist state, they having been exposed to the weather so as to become moistened through, and then what is known as bleached. Another very excellent dressing is air-slaked chalk lime and dry soot in equal parts by measure, using $\frac{1}{2}$ lb. per square yard or 15 lbs. per rod, point in with a fork about 6 inches deep, taking small spits and mixing evenly. This acts well both as a manure and pest destroyer.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*A. E.*).—*Stenotaphrum glabrum variegatum*. (*C. P.*).—*Anthericum variegatum*. (*J. H. S.*).—1 and 2, *Dracenas*; these are florists' varieties that can only be named by comparison; 3, *Statice profusa*; 4, possibly a *Diosma*, no flowers; 5, a *Gymnogramma*, send fertile frond; 6, *Franciscea latifolia*.

REAL OLD CHESHIRE.

DOES it exist now, or is it, like many other good things, only a fancy of the imagination? That we yearly eat a great deal of cheese that never had the slightest acquaintance with a British cow is perfectly certain. We do not for one moment say it is not good cheese, but we do object to paying English prices for a foreign commodity.

Since the commencement of this decade agricultural affairs have assumed a very black outlook. Nothing that the farmer grew or reared could be disposed of so as to leave a margin of profit, but still from one small western county the cry of depression had not been raised. Cheshire, with her fine dairy land and her name for world-famed cheese, held her own; but, alas! on Cheshire farmers at last the storm has broken, and the years of 1895 and 1896 will be accounted as years of great disaster. When things are at the worst the proverb says they mend, but now-a-days we hardly know when we have reached the lowest depths. Whitchurch in Cheshire has a noted cheese fair—or as it is locally called a cheese "pitch"; here the cheese is sold wholesale to the factors, who in their turn supply the shops and warehouses.

The value of Cheshire cheese retail ranges from 9d. to 1s. per lb.; the value of the same cheese wholesale this autumn was from 46s. per cwt. to 20s. per cwt. Someone gets an enormous profit, but it is certainly not the maker.

A dry season in old days caused a certain rise in the value of cheese, and the maker was sure of a fair price. Now all parts of the world are brought so near that any shortcomings in Cheshire are made good by distant lands, and the farmer has to bear the loss by drought without any proportionate rise in price as compensation. Cheshire and Stilton have been *par excellence* the cheese of Englishmen, and for a good cheese the consumer is always ready to pay a fair price.

Nature hurries none of her processes, and men were wise while they took her for their guide. This is the age that looks for quick returns. A year is a long time to keep a cheese on hand, but our forefathers said that many a cheese took that time to fully ripen and mature.

We call in the aid of science to ripen our cheeses in a month. We want to see the milk and the money nearer together. But see the result. Such cheese can only be used for immediate consumption; it has no keeping properties, and once a cheese begins to go wrong the case is hopeless.

The maker by his rapid methods is simply cutting his own throat, is throwing away a great and notable industry, and playing into the hand of the foreigner. Good cheese and cheap can be had from many countries, but the British farmer finds his greatest rivals in the United States and Canada. There was a time when a bit of "American" was about as nasty and tough a morsel as a man could eat, but now the case is quite altered.

In the year 1895 we spent 5½ millions on foreign cheese. The United States took £1,608,405, and Canada £2,688,946. Since then the supply from these sources, especially from Canada, has been much reduced, and a considerable increase of price has been the result; so cheesemakers are again buoyed up with hope for the future. But what has happened once may happen again; the Canadians have turned their attention to butter making at present, but they may return to cheese. What the dairy farmers must do is imitate the example of their competitors—make a cheese that will keep as long as it is wanted to, then the undue forcing of unnaturally ripe cheese on a glutted market would be unnecessary, and would hardly occur, as the supply could be controlled to suit the demand.

We as consumers have been tempted at times to invest in a piece of ripe cheese (too ripe), tempted by price, but we cannot remember getting anything but disgust from such a purchase, and have vivid recollections of cheese funerals. Is it any wonder, then, that the public fight shy of such gay, though strong, deceivers, and that merchants have perforce to do the same?

Every year seems to increase our foreign competition. Cablegrams and steam have much to answer for. Cold storage on board ship can be applied to any article of food, and new countries are constantly being opened up.

What will the rich pastures of Argentina do in the near future? There are long-headed men there, cheese plant is easily transported, and cheesemakers too for the matter of that. We have let our best butter trade slip out of our fingers, and it is only by slow and arduous steps we are getting a portion of it back again. It will never do to lose what has hitherto been one of our specialities simply because we are so bent on making haste to be rich. "Haste comes of the Devil," says the old Spanish proverb. We have had a sharp lesson, may we profit by it.

This subject of cheese-making is a very wide one, and a real "artiste" in cheese is a clever person. Some few years ago when there was such an outcry about butter, and butter makers as teachers were in great request, hundreds of girls rushed into the business; it was fairly easy, clean, and pretty well paid. The consequence is that now the market is overstocked, and we know at this present moment in our own small circle of eight really excellent practical teachers who cannot find a day's work.

Just at the same time, when everyone was yearning for butter-making work, came a note of warning, and eager learners were urged to take up cheese-making as a serious pursuit; but the hours were long, the work tedious, and no one, or at least very few, hearkened to the prophet. There is a great field here for the industrious sensible woman—a field she will have to herself, for no dilettante worker need apply for this post.

Professor Fleishmann says (and no greater authority exists), "The art of cheese-making is much more difficult than that of butter-making. In cheese-making a large number of different conditions have to be reckoned with, and their different influences have to be considered and weighed in relation to one another, so that they may all conduce to their definite and prescribed end. To do so requires a certain measure of skill and experience. . . . The art of cheese-making requires two different qualifications—a clear understanding on the one hand of the nature and action of all the processes which come into play in the manufacture of cheese, and on the other hand the particular object which must ever be kept in view in all these processes and in the manufacture of all kinds of cheese."

WORK ON THE HOME FARM.

The weather has again been fine except for one very wet night; the effect of this, however, was soon neutralised by high wind, and the land is little the worse. The drill is at work now almost everywhere, and spring corn is going in well. Everyone seems anxious to sow early this year, and after last season we do not wonder at it. On any but the very lightest soil we do not doubt that early sowing is the right thing if the seed bed be a good one; but good it must be, or the best results must not be expected.

We have got the Wheat rolled and some harrowed. We think farmers generally are too much afraid of harrowing Wheat, they are frightened of harrowing a little up; but the Wheat always branches to such an extent after harrowing that all losses of plant are more than recouped.

Lambing is now in full swing. So far luck has been good. A fair fall of lambs, and with good health a small loss. This is generally the case in a season of Turnip scarcity, for breeding ewes may easily get too many roots, and do so when they are plentiful. The ewes with pairs require better food than those with but one lamb. A mixture of Oats, cotton cake, and malt culms makes a capital milk-producing food to give with Mangolds and grass. The sooner the lambs are got out into the fields the better; in fact, in the case of singles, the weather being mild, it is best never to house them at all. Of course pairs must be penned until the mother has quite made up her mind to adopt both, and the weakest lamb is well able to get about after her.

When half the lambing season has passed over safely, and with good success, it often happens that there is a change for the worse; the ewes seem subject to attacks of feverishness after lambing, and take a good deal of nursing up, whilst some cases end fatally. As soon as a second or third case of this kind is noted the best thing to do is to move the ewes to a new lair altogether. If a fresh lambing fold for night lair cannot conveniently be provided the old one must be cleaned out, watered with disinfecting fluid, and rebedded.

OUR LETTER BOX.

Cow Keeping (Novice).—The 18 acres of grass will be useful for the cows only for two months, August and September, though they might be allowed to run out during the day as long as the weather kept mild. The cost for the rest of the year would be for 3 acres of grass from May 1st to August 1st, £5 (this would vary with the locality). Winter keep varies very much according to circumstances, but £10 each ought to pay for the best of food from October 1st to May 1st. Add £5 for bedding for the three, and you have £40 for the year. This does not include attention. We forgot to allow for cake on grass, say 5 lbs. each of cotton cake per day; this would add £5 more, and would be necessary, especially after June.

28th.—Generally overcast, with a little drizzle in evening; gleams of sun at midday.

1st.—Bright sun all morning; slight showers in afternoon; rain from 6.30 to 9.30 P.M.

2nd.—Bright sun generally till 8 P.M., then halo, and overcast after; strong gale with heavy rain at night.

3rd.—Dull and rainy early; wet snow from 11.30 A.M. to 0.30 P.M., turning to rain; dry after 2 P.M., and sunny about 4 P.M.

4th.—Sun early, and from noon to 3.30 P.M.; overcast, with sharp showers between and after.

5th.—Sunny almost throughout.

6th.—Overcast with frequent rain in morning; fair afternoon with a little sun; rain again from 9 P.M. to 11 P.M.

Temperature near the average, rainfall above it.—G. J. SYMONS.

BARR'S

EARLY DWARF "BEST OF ALL" CAULIFLOWER.

Remarkably early, dwarf and compact, with heads as white as snow.

Per Packet, 1s. 6d. and 2s. 6d.

BARR'S

CHAMPION SOLID WHITE CELERY.

Very solid and sweet, remaining longer in condition than any other White Celery.

Per Packet, 1s. and 2s. 6d.

BARR'S

NEW THICK-FLESHED TOMATO.

Surpasses all other Tomatoes in depth of fruit, solidity of flesh, high quality, and heavy cropping. Per Packet, 1s.

BARR'S

SPECIALTIES IN FLOWER SEEDS FOR 1897.

BARR'S SUPERB MIXTURE OF GLOXINIAS.

Seed saved from a selection of the finest named varieties. Certain to please. Per Packet, 1s. 6d., 2s. 6d., and 3s. 6d.

BARR'S EXTRA SELECTED LONG-SPURRED COLUMBINES.

A very choice mixture. Flowers of great beauty in form and colour. Per Packet, 2s. 6d.

TREE LUPINS, mixed, saved at the "LONG DITTON" Nurseries from 10 beautiful delicate shades. Per Packet, 1s.

BARR'S

NEW SEED GUIDE FOR 1897

will be sent free on application.

CANNAS! CANNAS!

Thousands of young plants now ready for despatch. All the Latest Novelties from France, America, Italy, &c.

Prices from 75/- per 100. Catalogue Free.

J. R. PEARSON & SONS,
CHILWELL NURSERIES, NOTTS.

CARNATIONS, PICOTEES, AND PINKS.

WE have pleasure in offering the following strong, well-rooted plants, securely packed and forwarded per Parcel Post or Rail, carriage free, to any address on receipt of stamps or Postal Notes for orders of not less than one dozen.

ANNA BENARY, white, barred carmine, immense flower, extra, 9d. each; 7/6 doz.

DUCHESS OF FIFE, beautiful rose-pink, 9d. each; 6/- doz.

GERMANIA, pure yellow, 6d. each; 5/- doz.

MONTAGUE, scarlet, immense flower, 9d. each; 7/6 doz.

MRS. FRANK WATTS, pure white, large, extra, 9d. ea.; 6/- doz.

MRS. MUIR, white, heavy shell petal, very free, 6d. each; 4/- doz.

MRS. REYNOLDS HOLE, terra cotta, novel shade, 6d. ea.; 5/- doz.

LEANDER, deep yellow, immense flower, very hardy, 1/- each; 9/- doz.

SACOHARRISA, lemon-yellow, barred lake, large, robust habit, 1/- each; 9/- doz.

SALAMANDER, deep salmon, very free, 9d. each; 6/- doz.

THE BEAN, orange, novelty, extra, 1/- each; 9/- doz.

URIAH PIKE, crimson, Olive-scented, extra, 9d. each; 7/6 doz.

One of each of the above 12 hardy border varieties for 6s.; a pair of each for 11s.; three of each for 16s. Post or rail free.

PICOTEES and CARNATIONS, choice named varieties, our selection, 5/- to 9/- dozen. **MIXED VARIETIES**, unnamed, in great variety, 3/6 dozen; 20s. per 100.

PINKS, in choice laced sorts, 3/6 dozen.

" **ERNEST LADHAMS**, blue, claret centre, immense flower, 4/6 dozen.

" **MRS. SINKINS**, pure white, 3/- dozen.

Seed and Carnation Catalogues sent on application.

NEW AND DELICIOUS MARROWFAT PEAS.

As introducers of the famous Stratagem, Telephone, Daisy, and Telegraph Peas, we invite a trial of the following New Varieties, all of which represent the most advanced types in the different sections for Garden Use, and will make their mark.

CARTERS' SPRINGTIDE.

A first early wrinkled Pea, as early as the smaller-podded round-seeded varieties, with the delicious flavour of the Marrowfat. Height, 2½ feet.

In Sealed Packets, 2s. 6d. per pint; 4s. per quart, post free.

CARTERS' EARLY MORN.

Another fine Marrowfat, with very long pods, a good colour, and well filled, almost as early as our Springtide. Height, 2½ feet. Stock very limited.

In Sealed Packets, 2s. 6d. per half-pint, post free.

CARTERS' ST. OSYTH GEM.

A cross between Chelsea Gem and Stratagem, combining the best points of both these excellent kinds. Very early. Height, 1½ feet. In Sealed Packets, 3s. 6d. per half-pint, post free.

CARTERS' SEEDLING.

A New Maincrop Marrow, the result of crossing and interbreeding from the three popular varieties, Stratagem, Queen, and Autocrat. Its pods are amongst the largest we have ever seen, and we have counted as many as thirteen Peas in a pod. Height, 3 feet.

In Sealed Packets, 3s. 6d. per half-pint, post free.

CARTERS' DAISY

Is a New Marrowfat Pea that embodies the best features of an ideal variety—viz., earliness, habit, size of pod, and delicious flavour. Carters' Daisy is not a selection, but creates a distinct break in Marrowfat Peas. Its merits have received recognition from the Royal Horticultural Society on more than one occasion. Dr. Masters, F.R.S., inspected our crop, and illustrated this remarkable Pea in the columns of the *Gardeners' Chronicle*. Height, about 1½ feet.

Copyright [J. C. & Co. New Hand-picked Seed in Sealed Packets, price 2s. per pint, 3s. 6d. per quart, carriage free.

CHANGES.

IN this world of infinite variety changes are ever occurring—some to sadden, others to cheer. Alternations of sun and cloud, of storm and calm, have of late been familiar incidents. Days of brightness have been followed by more of depressing gloom. The budding trees inspire with hope, and flowers, pure and bright, greet us with their welcome smiles.

Then are we made glad, and even joyous for the moment; but soon comes the boisterous wind, the driving storms of hail and rain to shatter, then again a calm to repair the damage done to tender growth. We rejoice in the quick recovery, and hope on again that all will yet be well; but doubts spring up, and cannot be repressed, that this may not be so. Then comes the chilling frost, and we shudder as we think and feel and grieve over the dire result—the cutting short of fresh young life in its very infancy.

Such has been the experience of many—of all who have spent long years of happiness and anxiety in the garden, for there cannot be one without the other, among those who love and labour in it. It will be the same with others to follow—those still young with buoyant hearts, but their turn and time will come to share in the disappointments incident to life, through changes that chill and crush and which cannot be averted.

There are other changes—less fitful, less violent, but more uniform, certain and sure—those imperceptible changes, but eventually so visible and important in results, those inherent to steady progressive growth, from tender plant to stately tree, from leaves to blossom, from blossom to fruit, and the advancement of this to maturity. When its course is run it ripens and falls, it has done its duty. Its purpose is fulfilled, and the end has come; but the tree lives on, and is prized for what it has given us of the richness of its resources over many years, and still more is hoped for, no matter how many crops it has borne.

For a time, even a long time, it does not fail us, but eventually signs of exhaustion become apparent. We may seek to restore the lost vigour, and may appear to succeed for a while; but feeble-

ness returns, and the fact is forced upon us that the life's limit of the tree is approaching. Still we cherish the hope that the sun of spring will awake it from its winter's rest, but in vain. The end of the once vigorous and fruitful tree, now old, has come at last. Those who have known it long and loved it well grieve over its loss, and recount its famous doings in the past.

So it is in human life. The young succumb through adverse contingencies, the old remain to ripen and in time they fall, leaving a blank never to be filled in like manner again. A great tree fell in the garden of humanity when Dr. Hogg sank quietly to rest in charity with all men in the early hours of Monday morning last—an event that will be memorable in the annals of horticulture.

Further reference to the deceased gentleman will be found in subsequent pages.

OUR HARDY PLANT BORDER.

HONESTY (LUNARIA BIENNIS).

THE gardens of the wealthy are commonly occupied with choice exotics, effective either for foliage or flowers; but are some of the old plants that were favourites in our grandfather's time as often grown as their merits demand? Honesty is certainly one of those that with ordinary care and judgment in selecting suitable situations will give ample return for the attention accorded, though it is excluded from many gardens. Perhaps one reason for this is because the variety best known has flowers of a purplish colour, a tint which is not in fashion, and ladies frequently condemn it on this account, though when they have seen a bed or border of vigorous plants in full flower their opinion has been known to change, as ladies' ideas in such matters will do occasionally.

There is something peculiarly stately and distinct in the habit of a well-grown biennial *Lunaria*. The foliage is not unlike the greenhouse *Cineraria* in size and substance, but more angular, and with longer leafstalks, the leaves radiating evenly from the central stem; then when the branching inflorescence is fully expanded a fine pyramidal specimen, 3 feet or more in height, is obtained that cannot fail to attract admiration. The contrast between a weakly ill-treated plant and one that has had its requirements properly studied is as great with Honesty as it is with others that come under the cultivator's care, and it is easy to understand how a plant acquires a bad reputation.

The objection as to colour is overcome to a considerable extent by grouping the purple and white varieties together either in beds or in neighbouring lines, the dwarfer habit of the white form rendering it suitable for a front line or margin. A white-flowered variety of *Lunaria biennis*, according to the books, has been known for 300 years, but it is much more rarely seen than the purple form, and is strange to many persons who are familiar with the common one. The white form we have seems, however, to be distinct from this, and is much smaller in all its parts, except the flowers, which are of the usual size and of a peculiar solid white that is rare amongst flowers, especially those derived from purple or crimson specific types. The leaves are dark green, and the appearance of the plant is altogether so compact and pleasing that it is worth more attention for itself alone, while as a companion to its coloured relative it is invaluable.

One product of the *Lunaria* is greatly valued—namely, the rounded silvery white inner partition of the seed pod (from the fancied resemblance of which to the full moon the generic name is derived), and where these can be allowed to remain until they are matured huge bunches can be obtained that are unrivalled for room decoration in winter, especially if something furnishing bright colour can be associated with them, such, for instance, as the expanded seed vessels of *Iris foetidissima*. Obviously when it is desired to secure the Honesty seed pods the plants must not be placed in a conspicuous position, for they have a very untidy appearance until the inflorescence can be cut away.

In the culture of Honesty the two most important points which in our experience influence the results are early sowing and early transplanting with the greatest possible care. The first or second week in April, if the soil is in good condition, is a good time for sowing the seed, ordinary well dug but firm soil being suitable, and we have found the seedlings do best without any manurial aid in their first stages. The transplanting must be done immediately the seedlings have produced the first leaves after the cotyledons, for strong downward roots are a characteristic of the *Lunaria*, and if these are broken or damaged when more progress has been made the plant never properly recovers. Every root must be preserved, and the planting should be preferably done

when the soil and atmosphere are moist, otherwise watering will be needed frequently until the young plants have become established. Unsatisfactory results are more frequently due to late or careless planting than to any other cause.

It is usually advised to plant this *Lunaria* in partially shaded positions or near shrubberies, and in a general way the advice is sound, but an instance may be cited in connection with the shade recommended as necessary which shows how difficult it is to generalise in dealing with the behaviour of plants. One of the finest displays of Honesty we ever had was in a narrow border immediately in front of a lean-to vinery facing due south, which being situated at a high part of the garden had the full effect of the sun all day. Yet the plants grew here most vigorously, produced handsome foliage, and flower stems 4 feet high. The soil was, however, rich, firm, and moist, for it was connected with the vinery border, and that being rather small was frequently and heavily watered. Beyond this, too, the plants were put out very early, and had well rooted in the soil before the sun had gained power enough to be injurious. In front we had a band of white Pinks that flowered early, and when we could get the two together, as we did sometimes, the effect was very pleasing.

In the border now under consideration the heavy moist soil undoubtedly suited the plants, but there was little difference in their behaviour in the shade of trees, or in the open where the other conditions had been provided. Nitrate of soda in very small quantities has a stimulating effect upon these plants if used early in June, so that there is time for the growth and leaves to become well developed and firm before autumn. The lightest sprinkling around the plants increased the size of the leaves greatly, and affected the subsequent development of the flower stems in the same marked degree. Sulphate of ammonia has a similar influence, but not quite so marked, and we prefer the former; while superphosphate or potash had little perceptible effect, though we fancied that where the superphosphate was employed the seed pods were somewhat larger, but this was not determined accurately, though it will be noted another time more carefully.

To insure the best results with the seed pods for home use, they should be gathered as soon as they are perfectly ripened, and the seeds can be seen within; if left too long they are liable to become discoloured, and are then useless for decorative purposes. The stems are cut off near the heart of the plant, tied together in loose bundles, and suspended in a cool shed where they will be safe from damp, and can dry gradually. The two outer valves of the pods must be removed by hand, as the partitions are easily split, and no other method that we have tried is satisfactory.—A COUNTRYMAN.

(To be continued.)

AS OF A DREAM.

I THINK "A. D." gave very good advice on page 95 about planting trees. It has set me thinking of the long ago, and to resuscitate notes which were ship-shaped for these pages in its first issues under the cognomen of the "Cottage Gardener."

Memory! Why I seem to remember it as well as if it only occurred yesterday. I was a very precocious gardener; began in fact by destroying my mother's household store of wooden spoons through using them for spades. This caused my father to buy me a toy spade at our neighbouring town of Bury St. Edmunds. I very soon afterwards made cause to try this "spade's" capabilities; and I had uprooted a good portion of newly planted Gooseberry "trees" before it was discovered what I was about; but I uprooted also during my labour a tiny Ash seedling, which a born instinct must have caused me to replant in a narrow strip of flower border flanking the wall of our cottage on Rushbrook Green. Well, there the sapling remained. My mother would not allow it to be removed till it became so large it began to undermine and endanger the house. Eventually the tree was planted in the park by Mr. Joseph Wigg, who was gardener to the late Col. Rushbrook for many years. The replanting of the tree was a subsequent cause of many Ash trees being planted in the park by Mr. Wigg. They had arrived at a good size when I last saw them twenty-two years ago, but I shall hope to see them again before I die. At any rate "A. D." can learn from the above that I began to do what he now recommends ever so many years ago, and he can tell you, if he feels so disposed, that he has been familiar with a good bit of my latter days' work in this respect.

I will return to A.D. 1820. Age and mischief increasing, I was sent to the village dame's school. After a spell of some two years, and learning but little, Dame Westley was very glad to be rid of me, as I never could desist from "worritting the flowers and things in her garden." Poor old soul! she might as well have included herself in the observation.

Thence for two to three years' more spell at a school in the neighbouring parish of Rougham, experiencing many canings. "Old Dicky Harrison" had a garden, with a pond surrounded by banks of Strawberry beds, which we used to water with cow's horns attached to the ends of long stout handles. His Filberts and Cob Nuts! and then the Apple gathering time, or any other chance when the fruit was there, in the fine old orchard! "Jim Hazlewood, my worthy fellow sufferer, are you alive to remember?" Are there many of us alive now to remember the holding up with his outstretched arm that capacious silver "ticker" to the very moment when it was time for "all in?" a good, kind-hearted man—peace to his manes.

I had not long overshot the age of ten, with but rudimentary knowledge of the R. R. R.'s, when I was taken away from Mr. Harrison's—it was no joke for fathers to pay for "schooling" in those days—and placed as a page to the young ladies at the Hall and their governess. A full share of my occupation was to attend upon them in their flower and kitchen (save the mark) gardens. This employment suited me very well, but how I disliked the governess! I have been told, too, that as soon as I entered my "teens" I became unmanageable—objected to take up the flowers or what not under a reasonable time to "see if their roots were growing." An idea, too, began to strike root in my

some old, worn-out cider Apple trees in the orchard, to be replaced with young ones of superior kinds. It was thought to be something akin to sacrilege in those parts then to destroy an old cider Apple tree. Jones was the factotum of the vicarage—sexton and parish clerk—endowed with a voice magnificent, coming as if, as he always read it, from the "depths of the sea." And to hear him sing! Well, I could give a comparison, but you might not like me to do so. Ah! Jones, Jones! you were a man of ample rotundity and of infinite humour. When shall I look upon your like again?

A coincidence to become indelibly printed on my memory happened as I was finishing the planting of some young Sycamores behind the church, to eventually screen it from a dirty farmyard and buildings. Williams—he lived in a pretty cottage at the "Hope"—was foreman to Lord Craven's workmen for his woods and plantations, passed by, and made the remark contemptuous, "I wonder who we shall have for woodmen next." I replied, I wondered so too; that I should like to be one vastly, for by what I could judge or had learned from him it was a very easy lucrative employment. I retain Williams in my mind's eye—a stalwart man, enveloped in a long white smock; so having portrayed him I will enclose for your ocular inspection two pictures as being intimately connected with my subject.

FIG. 50.—STANTON LACEY VICARAGE IN 1837.

mind comparatively, I likened myself as being the oldest son of a poor man, analogous to the youngest sons of a rich man; both had to turn out first to seek their living; besides, I wanted to be off, and the "governess" expedited me.

An opportunity offering I was placed at a watchmaking and working jewellery business in Knightsbridge. I could not become reconciled to the confinements of solderings, repairings, and cleaning of watches and clocks, so in less than two years I ran away, became *perdu* in the neighbourhoods of the London docks trying to get a berth as "cabin boy" to go to sea in any ship that would offer to take me. I could not; so after being sworn at by some authority or other on board, or laughed at as the case might be by the sailors; and then having spent or become cheated out of my limited stock of money, I was compelled to make my whereabouts known to the folks at home. How I escaped without blemish by associating with the lowest of the low some three weeks in the purlieus of the docks is a mystery to me to this very day.

After a time an opportunity offered, temporarily it was thought, for me to become located with the Rev. G. W. St. John at Stanton Lacey, near Ludlow, in Shropshire, a young man whose uncle, the then Earl of Craven, had not long before presented him to the living. Mr. St. John was just about completing the building of his new vicarage house. He was fond of poultry and pigeons, and I was to attend chiefly to their wants. But above all things I soon found that my propensity for planting could be fully gratified, so I felt myself at home, and gained a bad name quickly through winning Jones over to assist me in uprooting

The church depicted, about the time for which I am writing, had been made to undergo repairs, with readjusted seatings. A new south window, more in Gothic unison with the others, was substituted for the horizontal manufactory-looking affair, which had admitted light for possibly more than a century, right across the south limb of the structure, as I have etched it.* The large trees shown were, and may be growing there now, old Sycamores. The foreground flanked the public road, which had the newly planted shrubberies of the vicarage for the other side. Young Elms in line were placed bordering the eastern part of the churchyard, not shown.

The water colour drawing of the house and grounds was taken by Mrs. Stackhouse-Acton, daughter of Thos. Andrew Knight, Esq., the then President of the Royal Horticultural Society, in commemoration, the newly planted Apple trees in the foreground being the chief instigation for it. A sunk fence, or haw-haw, separated the lawn from the orchard, scarcely to be seen in the drawing. The large tree in the foreground by the bank of the river was a grand old Barland (Cheat the Boys) Pear. In a good season I had made as much as 3 hogsheads of perry with its fruit. The orchard extended some 1½ acre to the right (not shown), and 200 yards on the left. The distant outlines forming a background represent the Cleve Hills. Behind the large old Yew depicted upon the right hand from the house was the

* An excellent sketch, such as any gardener might be proud of, but we have only space for one illustration, and choose the more gardenesque.

kitchen garden and my Potato trial grounds. I was in earnest so long ago as then "beating about the" Potato "bush" by selections from the best.

I find you will not be able to afford me room in this issue to allow me to complete what I want to say about the memorable plantings, but you may perhaps find space to admit the detail of a circumstance which happened almost on the spot where Mrs. Stackhouse drew her pretty picture. Almost every farm around there pertaining to a fair size had its limekiln, and plenty of stone for the getting to burn into excellent lime, which I availed myself of largely in the year of the fatal Potato disease, 1847. I remember I was very busy dusting quicklime over the stricken haulms, when Mr. T. A. Knight of Downton Castle, and the Hon. R. Clive, M.P., of Bromfield Park (neighbouring parishes) called. Both gentlemen were enthusiasts in the cultivation of the esculent. They called on Mr. St. John, to consult possibly, as we were becoming "an authority" on the Potato, about the sudden infliction. All strolled to the "trial ground," and caught me in full blast upon a patch of the "Birmingham Blue." "Dusty Miller" could have answered for my appearance. I had often hob-nobbed with Mr. Knight, and I was not unknown to Mr. Clive. The visitors said, in fact I knew, they were trying different specifics upon their Potato haulm. They decided also to use the lime. I learnt afterwards that every nostrum failed, as the lime did with me, to check the fatality.

Papers are now appearing in the "papers" about some desirable new vegetable being invented in com —. I have a new species of *Solanum tuberosum*. The seed was sent to me from Mexico last spring. I have raised some beautiful little tubers from it. I had also another wilding sent to me from "New" Mexico twenty-two years ago, and if it takes me as long to bring my new comer into the same promising productive capabilities I shall have attained to the age of over 100. It is expensive work, though, is the raising of new varieties of the esculent, for however excellent they may be one cannot secure a patent, or even the credit of having raised them. But this *par parenthesi*s. I have much more to do and unfold to you (if the workhouse do not prevent it) re the noble tuber; after my two parishes' overseers' audit, for which I have received notices, I shall have to return again to Stanton Lacey in 1837 before I detail my experiments with the murphies in 1896.—ROBERT FENN, *Sulhamstead*.

DUKE OF BUCCLEUCH GRAPE.

I AM often asked about this Grape, and have written much privately to gentlemen in various quarters regarding it. It has occurred to me that if I were to state in the columns of the Journal a few of the peculiarities of this noble Grape it would save me some trouble, and be advantageous to many. They have been treated before, it is true, but that is some time ago.

First of all I would remark that "the Duke" is a splendid Grape, raised by my late father when at Dalkeith, and named after his noble employer, the late Duke of Buccleuch, at his special request. It has, however, certain peculiarities of constitution that require special treatment, and it is to these that I would like at present to draw the attention of all who think of going in for the cultivation of "the Duke."

First of all, I may remark that it fruits best on the young wood, therefore it should be the aim of all its cultivators to maintain a succession of young rods. Then when pruning, the spurs should be left at least three or four eyes long. When the Vines break the best shoot can then be retained, and the others removed. "Tying down" should not be done as soon as in the case of most other Vines, as "the Duke's" shoots are very strong, and at the same time rather brittle.

Supposing that the "tying down" has been successfully accomplished, the next thing to consider in the culture of the Duke is the "setting" of the bunches. We have always found that artificial impregnation is required, and in addition to shaking the Vines we go over the bunches very lightly with an ostrich feather or a rabbit's tail. This insures a good "set." The next thing is the thinning. Let the berries be as big as possible before thinning, and then when one can judge of the proper "set" the bunches must be well thinned out, for the Duke has an enormous berry when well grown.

Sometimes, like the Muscat and Lady Downe's, the Duke is apt to scald a little during the stoning period. We have found a very slight shading, thrown on the glass with the syringe, quite sufficient to prevent this. Then when the berries are ripening the atmosphere should be kept as dry as possible, and water withheld from the roots.

With treatment such as I have described we have for many years grown the Duke to perfection, and only those who have seen and tasted this variety in its prime can realise what a noble fruit the Grape is. With a thin skin, one, or at the most two, stones in each berry, grand appearance, luscious flavour, and most refreshing and sustaining qualities, the Duke is well worth all the extra trouble that may have to be bestowed upon its culture.—JOHN THOMSON, *Glovenfords*.

ORCHIDS IN FLOWER.

AT no time in the year is the house devoted to flowering Orchids so gay and interesting as now, the number of choice things in bloom being remarkable. Almost every genus has a few members that flower during the present and succeeding months, while many—such, for instance, as *Dendrobies* and *Cypripediums*—are giving us of their choicest. The number of *Cattleya* species in bloom is not great, but so rich are they in varieties that they are quite a host. Take *C. Trianae* as an instance of this. From the lovely pure white *C. T. alba*, with only a dash of orange in the throat, which enhances its beauty, we have a chain of intermediate forms to the brightest rose, the markings on the lip being especially beautiful in some of the paler forms.

I consider the most beautiful varieties are those having the colours well defined and clear, the splashed sepals and tints running into one another lacking character. Anyone interested may easily see for themselves what pleases them by looking in at any of the large nurseries where these plants are made a speciality. A beautiful species too is *C. Schröderae*, elegant in form and delightful in its soft colouring, while getting away from the labiate group *C. intermedia* and the sweetly scented *C. citrina* find a host of admirers.

With *Cypripediums* one hardly knows where to begin, so numerous and varied are the species, varieties, and hybrids. *C. Argus* is well known and appreciated; rightly, too, for it is a capital species, but *C. Argus superbum* is much better, the flowers larger, brighter in colour, and more profusely spotted. *C. tonsum* is a very distinct plant, the flowers lighter in colour, while *C. Rothschildianum*, with its immense and highly coloured blossoms, is not likely to be forgotten when once seen in good cultural condition and well flowered. The hybrid *C. marmorophyllum* combines the beautiful foliage of *C. Hookeriæ* with flowers almost intermediate between this and *C. barbatum*, its other parent.

C. Calypso and *C. Lathamianum* (fig. 53, page 237) are two beautiful hybrids now flowering, while the well known and free-blooming *C. Chamberlainianum*, and the lesser known *C. Victoria Marie*, are also in full beauty. This latter has the same twisted petals, and the habit of flowering from close green bracts as *C. Chamberlainianum*. The foliage, too, is almost identical, but they are quite distinct from each other. *C. virens* is a curious species, the flowers almost entirely green, of various shades, but not large or showy enough to find favour at the present day.

Cymbidiums are in strong force; the chaste pure white *C. eburneum*, the popular *C. Lowianum*, and the hybrid kind raised between them making a fine show. Those who have not seen *C. Lowie-eburneum*, the later and better of the two hybrids raised between them, may be interested to know that the flowers are larger and brighter in colour, and retain the delicate perfume of *C. eburneum*. *C. sinense* is an old and not very showy kind, but worth a place, if only for its delightful fragrance, a single plant in bloom quite scenting a large house.

Dendrobiums, as mentioned above, are very numerous now, and not the least beautiful are the well-known *D. nobile* and its many choice varieties. *D. n. Sanderiana*, *D. n. albescens*, *D. n. pendulum*, and Wallich's *nobile* are only a few, but the list could be almost indefinitely extended. *D. crassinode Barberianum* is a superb thing. How often this name is seen, but how seldom the true plant! *D. Ainsworthi* is a beautiful hybrid, so is *D. Leechianum*, a better one from the same parents. This is only touching the fringe of what are in bloom, but to mention all would become tiresome. *Dendrochilum* (*Platyclinus*) *glumaceum* is an elegant and free-blooming Orchid, the arching scapes on a well-flowered large specimen being very beautiful, though the individual blossoms are rather small and insignificant.

Orange and scarlet Orchids are perhaps more freely represented now than at any other season, and include the beautiful *Lælia cinnabarina* and *L. harpophylla*, *Ada aurantiaca*, *Cochlioda Noezliana*, and a few rarer and lesser known kinds. *Masdevallias* are not yet in their prime, but I saw in a large collection recently about twenty species in bloom, the best known of these being *M. Shottleworthi*, *M. ignea* and its varieties, *M. militaris*, *M. Chimæra*, *M. bella*, and *M. speciosa*. The pretty hybrid *M. Chelsoni*, too, and its parents *M. Veitchi* and *amabilis* are all fine showy plants.

Odontoglossa are very numerous now, the first place naturally being taken by the cool growing New Grenada species and hybrids, including all the forms of *O. crispum*, *O. Pescatorei*, *O. luteo-purpureum*, *O. triumphans*—perhaps the best of all yellow species—*O. Andersonianum*, and dozens of others. *Oncidium*s are almost as numerous, the long scendent spikes of *O. undulatum*, *O. serratum*, and others in this section being hardly recognised as relations to the pigmy forms, such as *O. pulchellum* and *O. tetrapetalum*. In this necessarily incomplete list many Orchids now blooming are unavoidably left out, but those mentioned show what a rich floral treat may be got from these lovely plants.—H. R. R.

PRECEPT AND PRACTICE.

(Continued from page 178.)

THE Hygro-meter, literally moisture measurer (atmospheric); the Anemo-meter, wind measurer—guage (observe the relation of anemo to Anemone, the Windflower), are scientific instruments it is only necessary to mention now; but we may pause a little over the taking of levels ere passing to other subjects, not with the idea of pressing a matter which is possibly premature, but to excite some thought and interest in a roundabout way on what is probably regarded as a severely straight subject. One of the hardest facts to swallow in youth is that which teaches us our planet is a ball—"round like an orange, flat top and bottom." Hundreds of times have I repeated that formula, parrot fashion, with as little faith in it as Columbus's sailors, who were in hourly dread as they sailed west of tumbling over the edge. Our work being confined to an infinitesimal portion of this terrestrial ball, it follows necessarily that all our practice of this description is carried out on a dead level. That is the case, and so far as our work is concerned it is safe to say that the matter begins and ends there.

Yet it is as well for young students to voluntarily digest now a few of those facts previously swallowed under compulsion; to know that there is no such thing as a dead level in extended engineering on our magnified orange beyond the "flat top and bottom" at the frozen poles. A simple but glorious scientific revelation, over which many a puny battle has been fought with scepticism in the bothy. One lad argued the matter with me, and settled it to his own satisfaction by the logical (illogical) conclusion that the sea would run off (where to was not stated) if it was not level—level as he knew it. But the sea furnishes as good an illustration as we probably have within our powers of vision by observing some tall-masted vessel going away hull down over the brink, may I say, the last thing to disappear being the masts.

To all ordinary intents and purposes the spirit-level is adapted to our needs, which if placed upon a lath, or better still set into one of well-seasoned wood, planed level and true, of 10 or 12 feet in length is, with a handle attached, a convenient and portable instrument. With this I have carried out some considerable extent of practical work, although that has been chiefly limited to the forming of tennis and croquet grounds, but work of sufficient scope to show the necessity of some skill to prevent unnecessary labour and to insure success. Probably the early days and duties of a young gardener's life will afford but little, perhaps not any, opportunity for practical lessons in this direction, but there is nothing to prevent him from working out some simple problems upon paper, with the endeavour to include in his mind's eye some particular piece of ground in the locality. Without diagrams to illustrate the text I fear that any further digression would scarcely be justified, but I have great faith in the intelligence of young readers, and only wish to impress upon them the desirability of including such matters in their repertoire, that when called upon hereafter to play a practical part it will not come as a surprise.

In the early days of croquet—and that is a long time since—my first lesson in levelling of a negative kind was received. It was another of those instances of how *not* to do it, my worthy mentor being one of those who practically regarded lines and rules as fit for — (it rhymes), including the level. His eye was "good enough," but it proved to be a near-sighted policy. Soon after that my eyes were opened by being permitted to peep through a theodolite which it was my task to carry for a gardener whose practical knowledge had been called for in wider fields, and this gentleman was good enough to let me see other things as well, from which the moral may now be pointed that as a "head" it will be your duty to engineer such matters that the "hands" may be spared all unnecessary labour, that not one barrowful or cartload of soil is to be removed one yard purposelessly. "Mind rules, not muscle."

For the higher phases of our work it is essential that the eye should early note the fundamental lines of utility and beauty, which, indeed, are parallel lines, and by continual if voluntary exercise seek for perfect examples of their kind. These may be

seldom found, but the negative teaching is, possibly, higher teaching in showing what to avoid when a standard or ideal is formed. In the higher phases of life—our lives—it is the prerogative of all who possess the natural senses, who are rational, thinking beings to see, to enjoy, and in a great measure to understand the marvels of creation, the most minute of which transcend our greatest efforts, but all of which it is given to us to have dominion over. Therefore is the human mind endowed with viceregal power. Yet pass we on; we of all people who should hear the low whisperings, should see the deep beauty of nature, deaf, blind, till life half becomes a weariness, and this with all its compensating influences at our feet.

Perhaps I am going out of bounds, hence I will go no further, but return to the practical by asking our boys to open their eyes to this world of beauty around them. Some are, perhaps, situated in their sojournings, which to their mind compare unfavourably with sights and scenes they have left behind. I have seen it so; seen young men on their "Sunday out" lie in bed all day sighing mayhap for "the hills that are wild and majestic, the steep frowning glories of dark Lochnagar," and, somehow, when this spirit of discontent takes possession it often holds through life. Possibly in early life my case would have been the same, but the position was reversed, for escaping from the old home, which was under the fringe of the great London smoke cloud, to the wolds of Gloucestershire, I tramped the hills for miles around, hailing every known wild flower as an old friend, and the unknown as new ones. This may be a bad or at least a doubtful moral, but the lesson has long since been learned that wherever fate ordains for us to spend our lives there nature has satisfaction for us in some shape or form.

We should, it may be thought, find all this in our work—the work that early duties impose upon us, but that may for some considerable time be limited to a small portion of so large a subject. No! we cannot, we must not confine our attention to the vineries, the pineries, or even to the garden proper, but "zigzag" in all the little things which lay around us pertaining directly or indirectly to the vocation, and these may be anything, from a neglected tree to a thriving plantation, a satisfying landscape to a treeless waste, a fine example of natural rockwork, or a suburban monstrosity called a rockery; in fact, I hardly know where one could not go, or what one could not look at without seeing the way how to do, or *not* to do, some particular thing, for "They who truth and wisdom lead, can gather honey from a weed."

I daresay that there is not any young gardener who does not pick up a number of vague ideas, which he intends to carry forward for future benefits; but when the time arrives for using them, vague ideas will not serve—they rather tend to confuse, and hence become our master. Can you not skim the cream as you pass along, and mentally churn it into something solid, something good, something that will keep? Note all, good and bad; and let your mind be the separator, to your ultimate advantage. You will say, "Who amongst us novitiates are endowed with these high powers?" None, truly; but are there any who cannot cultivate their growth? None; but many, alas! who will ignore the necessity of doing so. To this end I will next endeavour to sow a few seeds from a prize packet—seeds only; and that, as I am well aware, for cultivation under difficulties, yet "To all the prize is open, but only he can take it who says, with Roman courage, 'I'll find a way, or make it.'"—AN OLD BOY.

(To be continued.)

HARMFUL AND HARMLESS GARDEN MOTHS—2.

JUST now, when the welcome influences of spring are calling forth so many animals and plants to a new life, the largest and presumably the strongest of our British moths is seemingly unaffected. All the males and females of the species are slumbering deep in the earth, protected by the chamber which was the last work of each retiring caterpillar. Yet it is true that with the chrysalis shell the warmth and moisture of the season are developing the future moth which is to emerge when summer is at its glory. A moth this of the fields, yet of the gardens too, for sweets attract it to those spots where flowers or fruit abound; and where bees are kept also the caterpillar is found at times upon various plants in enclosed grounds, though it more frequently occurs about Potato fields. Not by any means a common insect generally, but it is plentiful some seasons in a few districts, specially towards the West of England. It was rather, as a caterpillar, abundant in North Kent during the autumn of 1884, yet the moth was seldom observed either before or after.

This species, the death's head (*Acherontia Atropos*), which has also been sometimes called the bee tiger for a reason that will appear, has never, to my knowledge, been induced to deposit eggs in confinement; but probably, like its immediate relatives, it

deposits a good number—above a hundred, no doubt. Still, it shows no tendency to increase, but rather to diminish throughout the country. I do not think it is or has been made less common by the exertions of farmers and gardeners because, large as it is, the caterpillar does no serious damage to Potato crops, nor indeed to the other plants upon which it sometimes occurs. Of course, some of them are killed by the workers amongst Potato crops. In several counties the death's head caterpillar is known by the ridiculous name of "lokus" if it happens to be noticed. Generally it retires under the earth by day or rests upon it, feeding at night. This may be a natural precaution against the attacks of birds; possibly it is in danger from some species. Experiments in rearing this moth prove that it is rather liable to die from various causes instead of emerging from the pupal state. Then the species is sometimes the victim of ichneumon parasites, which, small as they are, kill the caterpillar before it reaches maturity. Again, there is another peculiar circumstance in its history—that most years, if not invariably, a part of the annual brood comes out on the wing late in autumn, about October or even November, and these moths die off without depositing any eggs.

The familiar English name of "death's head" bestowed upon this harmless and handsome moth is ominous enough; the Latin ones are equally gloomy, significant of death, and of the river, which, according to the myth, flowed in the infernal regions. All this arose from the thorax of the species in this genus bearing a mark resembling a skull or skull and cross bones. Superstitious fancies connected with our native example have had two opposite results in the minds of some folks—a desire to kill the creature, and also a fear of meddling with it should one approach. Now and then a death's head has appeared in a shop startling people considerably, being attracted no doubt by some odour such as comes from a grocer's. In some countries the moth is supposed to be the companion of witches, and to mutter mournfully as it flies the names of persons who are soon to die, or, from its happening to be common at the time of an epidemic, it has been regarded as a disease bringer. Even about England the entry of one into a house has been thought a sign of illness or death, and in Hampshire some villagers have the odd notion that the death's head moth was unknown till after the execution of Charles I.

An average sized specimen measures about 5 inches across the expanded wings. The body, head, and legs are thickly clothed with velvety hair; in colour it is chiefly brown, varied with yellow and black; the thick antennæ have hooked tips. Though it seems to be a cumbrous flier this moth is known to travel long distances, and is believed to cross the Channel sometimes. Short is the proboscis or trunk, hence the number of flowers from which it can obtain honey is limited, and the moth visits gardens or orchards partly to feast upon over-ripe and fallen fruit. July or August is the season of its flight, and the young caterpillars are about in September. They have been taken feeding on Jessamine in gardens, along hedges on the Bittersweet or Woody Nightshade, and other wild species of Solanum, also they will patronise the Snowberry and the Tea Tree (*Lycium barbarum*). Even in the same brood the colouring of individuals varies, shades of brown, yellow, or grey, but always black dotted and bearing seven bluish stripes, the tail having a rough and recurved horn. When full grown the death's head caterpillar is indeed a giant of the caterpillar race, and being an unarmed giant has reason to be wary in its movements as it increases in size. A search for it is most likely to be successful if made in the dusk of evening, or later, by the aid of a lantern.

All gardeners will have observed that caterpillars generally have no idea of acting on the defensive. Any large one, should it be annoyed, will attempt to bite, throwing its head about in an aimless way; but the jaws, so effective for cutting food, seem unable to pierce the skin of the hand, nor could they keep off a bird enemy. It is, however, the fact that caterpillars occasionally bite, and even kill each other; some, too, have special means of defence against their foes, and the death's head has the power, extremely unusual amongst caterpillars, of producing a sound. This was first noticed by a German entomologist (the insect is much commoner on the Continent than it is here), and he compared it to the snap of an electric spark. An English entomologist, who has reared many of these caterpillars, finds that some of them are less inclined than others to make this noise, meant, no doubt, to startle the meddlesome from too near approach. What offends this caterpillar particularly is to be tapped on the head. Mr. Paulton says his conclusion is that the sound is produced by the mandibles, which are large, and have a remarkable range of movement, so that they can bite over each other. On the outer surface of each is a transverse ridge, and when one mandible is gliding over the other towards the base it passes over this ridge with a jerk. The resistance and the clash of the hard membrane probably explains the noise.

While a torpid pupa the insect may be made vocal if it is near the time of emergence. An entomologist removed part of the mesh covering the head, and a sound was heard, which seemed to be caused by the tongue being drawn into the form of a bow and then flattened as before. This is, however, like that of the caterpillar, faint to that produced by the moth, and also different. Its plaintive cry has been compared to the squeak of a mouse; it is peculiar, and has no doubt, as remarked, much to do with the superstitious fears of the winged insect which exist in many countries. Some entomologists supposed the sound came from a special apparatus in the body, but it is now believed to arise from the friction of the proboscis or tongue against the palpi. The known visits of the death's head to bee hives suggested the idea that the moth by means of this sound alarmed or paralysed the bees, and thus avoided the danger of a sting. But I really can scarcely think an insect so courageous as the bee generally shows itself to be would be at all affected.

In Britain this moth has been noticed to haunt bee hives. Evidently it has no chance of entering the average hive of modern style; it can smell the honey, but it is unattainable. The old-fashioned hive did give access, and occasionally one would be found dead within; having entered it could not always escape. For sanitary reasons the bees, it was noticed, often embalmed the big body of the moth with propolis. On the Continent bee-keepers have found the bees construct a kind of fortification, sometimes just at the door, which excludes the moth. Entomologists seem to doubt whether the sting of a bee could penetrate the fur and cuticle of this species. To add one more fact, the insect has been perceived to give off now and then a pleasant odour like that of Jessamine.—ENTOMOLOGIST.

LAPAGERIAS.

THERE can be no doubt that these plants will bear low temperatures without injury, and a slight frost reaching them when grown under glass does not appear to injure them in the least. But in houses where the winter temperature is low, and the structure is also kept as cool and airy as possible in spring, the plants are placed at a great disadvantage in comparison with those that are accorded more genial treatment.

Under cool treatment throughout the year, or during the earlier months of the year, Lapagerias are naturally late in starting into growth, which largely influences the flowers they produce. The wood has no time to mature thoroughly, the flowers are late and do not possess that bright colour and size characteristic of good forms of *L. rosea*, while its white companion is too often tinged with pink. Late flowers of the last named, produced under cool autumn treatment, have in addition a greenish tinge that mars their beauty.

TEMPERATURE.

To grow Lapagerias freely, strongly, and rapidly, the structure in which they are accommodated should be kept close and moist from the present time, with a night temperature of about 50°. The conditions favourable for starting Azaleas and Camellias into growth after they have flowered are suitable for Lapagerias. They soon start into growth; in fact, if the temperature of the house in which they are growing has ranged from 40° to 45° throughout the winter, they will be ready for bursting at once into growth, and strong shoots will soon commence to issue from the base. By assisting them to make their growth early their shoots lengthen rapidly, and partially mature the foliage before the sun gains much power and shading becomes necessary.

Cold draughts cause the young tender shoots to flag nearly as much as bright sunshine does, therefore little ventilation is given before April, when it may be gradually increased until greenhouse treatment is given them from the middle to the end of May. The plants have thus a longer season of growth and abundance of time to mature their wood thoroughly. This is important if they are to bear flowers freely, large and bright in colour, or of the purest white. Gentle warmth, even during the close of the flowering season, will prevent their coming green or tinged with pink. This is certainly the result of a low temperature. The plants increase much more rapidly in size by the gentle assistance advocated than they are capable of doing by the cool airy treatment too often given them.

Where Lapagerias can be planted out they make greater progress than in pots. This is not because they like a large amount of soil for their roots to ramble in, but because they are not exposed to the same drying influences as in pots. Their roots require a cool position where a uniform condition of moisture can be maintained without having to be continually pouring water into the soil. In selecting a place for them, hot-water pipes, or anything else that may tend to unduly dry the soil, should be avoided. Tubs decay, or they would be better than pots, because they do not dry, however rapid evaporation may be, quickly enough to be a source of danger to the roots. Probably the next best method is growing them in large pots, and plunging these to the rims to prevent evaporation.

COMPOST.

The soil in which Lapagerias will flourish is not so important as many suppose, for I have seen them luxuriate in a variety of composts.

A safe mixture, however, is good fibry loam and peat, broken up with the hand and used in equal proportions. To this add a liberal quantity of coarse sand, a few half-inch bones, a 7-inch potful to each barrowful of soil, as well as sandstone broken up. The latter we prefer, because the roots cling to it tenaciously, and it keeps the compost sweet and porous. Press the soil moderately firm, for the plants do better in it than when it is light and spongy, which necessitates frequent applications of water. When the plants are limited to pots a greater percentage of peat may be used, or all peat, which remains in a sweet condition for a longer period than a mixture of peat and loam.

Good drainage is absolutely necessary, but the border in which they are growing should not be over-drained. Although they like moisture in the soil about their roots they cannot endure it in a stagnant condition. When the border is limited in size and it is once well filled with roots rich top-dressings are necessary. The surface should be annually removed down to the roots and good fibry loam supplied, with one-seventh of decayed manure, which will be found to assist them wonderfully.

The shoots are generally trained upright, especially strong suckers that issue from the base, and on the whole this is probably the best means of training them; in fact, strong growths should be trained after this fashion the first season and allowed to extend as much as possible. Strong shoots from vigorous plants will travel yards in a season. If left in this position they will break freely, and make a spreading head towards the extremity. They may be allowed to do this with advantage. But when there is space to fill time is lost, and the progress of the plant sacrificed by allowing them to remain in this position after the second season. Few, if any, of the lower eyes will burst into growth; they may remain dormant for years. Shoots of this nature, or old strong shoots that may have been trained upright, will produce a number of strong growths that will extend rapidly if they are laid horizontally at the base, and the weaker shoots at the top trained upright. Plants that are bare at the base will quickly be furnished with strong flowering wood by this simple process.

SYRINGING.

It is necessary to syringe the plants frequently to keep bare old stems practically moist for a time, until the buds swell and burst. A free use of the syringe is an advantage to the plants during the whole of the growing season, and should be discontinued only after the completion of growth until flowers are visible, when it may be continued until they show signs of expanding. If all the flowers are gathered a good syringing will prove beneficial. At the present time, on bright days, the syringe may be used twice daily, once will be ample on dull days. In May the syringe is used in the middle of the day as well as in the morning and afternoon. If young growths display signs of flagging during hot weather the syringe is used, and they soon revive.

Little need be said about watering, suffice it that at no season of the year should the soil become dry. During the season of growth liberal supplies are needed. If once the border is full of roots weak stimulants may with advantage be given every alternate time they need water during the season of growth. Fresh cow manure placed in a tank with a bag of soot is a capital stimulant. It should be given in a clear state, or strained through fine tiffany and well diluted with water. At this season of the year the water needed at the roots and for syringing should be slightly warmer than the temperature of the house.

Pruning is rarely practised with these plants, although a little is requisite each season. This should consist of cutting back the shoots that have flowered to a good eye. It keeps the plants free from dead and dying shoots, which would be the case if that portion which flowers is not removed. This is all the pruning needed until the plants have filled the roof or the space allotted to them. It is a mistake, then, to allow puny growth to crowd the roof, and a judicious system of thinning should be practised. The shoots selected for removal must be cut back to a good eye, and by this method the space can be kept furnished with strong robust shoots that will flower freely and produce finer blooms than weak, short, stunted growths are capable of doing. If *Lapagerias* are thoroughly established they will bear more pruning than many suppose, and with advantage. Plants that make scarcely any growth annually generally flower profusely, too freely in fact, and they are much enfeebled. They may be restored to vigour by pruning. This is the only means of saving them, for if allowed to continue flowering they become weaker, and finally dwindle and die.

ENEMIES

Nearly all the pests that infest plants will attack *Lapagerias*. Aphides are partial to them, but these are readily destroyed by fumigating with tobacco. Thrips are troublesome, but if the plants are freely syringed these will be kept in check. When established upon the plants fumigate with tobacco smoke two or three nights in succession, or thoroughly syringe with tobacco juice freely diluted with water, to which may be added half an ounce of soft soap to each gallon of water, and a piece of common washing soda the size of a cob nut. We prefer this to fumigating, only it renders the woodwork of the house unsightly. A solution of any of the insecticides recommended for the destruction of thrips may be used. It should be eradicated at once, for it quickly destroys the foliage and brings the growths of the plants to a standstill. If thrips appear when the foliage is firm and leathery a weak solution of petrolum and water, 2 ozs. to 3 gallons of water, will soon destroy it without injury to the plant. The same solution will destroy scale, from which the plants can soon be cleared if they are syringed two or three times in succession during the period of rest. Mealy bug is more diffi-

cult to deal with; it secretes itself behind the scales that protect the buds, and cannot be reached with the syringe. Patience and perseverance in battling with it are the only means by which it can be exterminated.

Shade is necessary during bright sunshine. At first for a few hours daily, but during the months of June, July, and August it is well to keep the blinds over the plants during the greater part of the day where they are grown in a structure facing south. As the growth matures it should be gradually discontinued, and dispensed with altogether by the end of September or early in the following month.—GROWER.

DEATH OF MR. J. CRUICKSHANK, FROGMORE HOUSE GARDENS.

To the numerous gardeners who, as "young men," have during the last fifty years passed through the Royal Gardens, Windsor, the news of the sudden death of Mr. Cruickshank will be received with much regret.

Although seventy-two years of age he enjoyed good health, and died practically in harness, as he was attending to his duties on the day of his death, March 4th. During the evening he complained to his wife of a peculiar sensation and pain in his chest and throat, and shortly before 8 P.M., while walking from the room, he fell, and died in a few moments from heart disease.

He came to the Royal Gardens from Castle Fraser, Aberdeenshire, in July, 1847; consequently, had he lived till July next, deceased would have completed fifty years in the Royal service. After serving as journeyman in the various departments for seven years he was appointed foreman in the Castle Gardens and slopes, where he remained another seven years; and when the Crown took over Frogmore House, on the death of H.R.H. the Duchess of Kent in 1861, he was appointed foreman of Frogmore House Gardens.

He was a gardener of the "old school," with a good knowledge of hardy plants and shrubs, also wild flowers, and could tell many a good tale of the rambles he took in Scotland in search of new and rare species during his bothy life. Being of a happy and genial disposition he was very popular, and never happier than when quoting "Bobby Burns," whose poems he seemed to have learned by heart.

The funeral took place at Windsor Cemetery on the 9th inst., and was largely attended, the remains being followed to the grave by Mr. O. Thomas (the Queen's head gardener), Mr. W. Tait (bailiff), all the foremen at the Royal Gardens, deceased's men, relatives, and friends. Among the many handsome wreaths sent to his funeral as tokens of sympathy and respect was a beautiful one of *Immortelles*, having on a card attached, 'From Queen Victoria.'

ROYAL HORTICULTURAL SOCIETY.

MARCH 9TH.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters (in the chair); Mr. McLachlan, Mr. Michael, Rev W. Wilks, Prof. M. Ward, Dr. Müller, Mr. J. T. Bennet-Poë, Mr. Douglas, and Rev. G. Henslow (Hon. Sec.).

Beetles with Grapes.—Mr. McLachlan had received some small beetles found about the roots of Vines, about a quarter of an inch long, with a blunt thorax and rather sluggish in manner. They proved to be *Trox sabulosus*, and were introduced in the crushed bones used for manure. Not being vegetable feeders they do no harm to the Vines. The best trap would be a dried rabbit skin with the inner side downwards.

Larvæ of Daddy Longlegs.—He also received a sample of propagating soil in which Iceland Poppies were grown, abounding with the caterpillars of this fly. Bisulphide of carbon, cyanide of potassium ($\frac{1}{2}$ to 1 per cent. solution in water), or to remove the soil and burn it, were methods recommended in such cases.

Apple Root with Adventitious Buds.—Dr. H. Müller exhibited a specimen, thickly covered in places with innumerable buds, usually known as "Burr Knot." The original cause is obscure, but Dr. Masters observed that such roots are often cut up and used for propagating.

Hyacinths, &c., with Root Failure.—A collection of bulbous plants were received from Mr. W. C. Atkinson of Aiglwath, Liverpool, in which the roots had been very imperfectly developed, but then arrested and decayed. Mr. Douglas undertook to investigate the case, Dr. Masters observing that the bulbs might not have been properly ripened before lifting.

Drift Wood from Arctic Seas.—Dr. M. T. Masters exhibited specimens of wood obtained by Dr. Nansen. They had travelled from Siberia to Franz Joseph Land, and consisted of the Siberian *Pinus cembra* (dwarf form), Willow, Elm, &c.

EXTINCT PLANTS.—The number of species of plants which have become extinct is very large, and yet generic groups rarely die out. Comparative researches show that much the greater proportion of plants whose remains have been preserved in a fossil condition from earlier geologic periods belong to the genera which are represented by plants now living, although many of these existing plants differ specifically from the earlier ones. From this it seems that new types are outgrowing the old ones constantly and take their place in the general scheme of life.

WEATHER IN LONDON.—Since last Wednesday the weather in London has been by no means pleasant. There has been a thunder-storm, snow showers, and downpours of rain at frequent intervals. Occasional gleams of bright warm sunshine have been very welcome. Some dry weather would do an immense amount of good.

— **WEATHER IN THE NORTH.**—Cold easterly winds, rain more or less every day, with a very rare watery gleam of sunshine and frequent sleety showers, have made up the record for the week ending Tuesday morning, the latter being fair but cold with no great promise of improvement.—B. D., *S. Perthshire*.

— **FRUIT PROSPECTS ROUND LIVERPOOL.**—In walking round the garden there is nothing at the present time more interesting than the rapid development of the fruit buds, and although we have had a few days of brilliant sunshine yet the weather of the past few days has been of such a nature as to retard them to a great extent. Of this I am glad, for I never remember seeing such a splendid promise of fruit as the trees present at the present time, from the youngest to old veterans of between fifty and sixty years' standing, espalier-trained and standards, and it would indeed be nothing short of a calamity if the unpropitious state of the weather should deprive us of bountiful crops.—R. P. R.

— **ROYAL HORTICULTURAL SOCIETY.**—Constant complaints having been made to the Council to the effect that the business of each of the Committees has lately been disorganised on account of the disregard of the Society's rules and regulations, the Council hereby direct that—1, The rule whereby all objects presented for certificate must be entered with the clerks at the table before 11.30 a.m. be in future rigidly enforced; and that—2, All such objects must be placed on the special table provided for plants for certificate. After the plants have been presented to the Committees they can, if the exhibitors wish it, be incorporated in their groups. The next Fruit and Floral Meeting of the Royal Horticultural Society will be held on Tuesday, March 23rd, in the Drill Hall, James Street, Westminster, 1 to 5 P.M. A lecture on "Bud Transference and its Effects on Fruit," will be given at three o'clock by the Rev. Gordon Salmon, M.A.

— **BERLIN INTERNATIONAL HORTICULTURAL EXHIBITION.**—We are desired to announce that a great exhibition of horticultural products will be held in Berlin from April 28th till May 9th of the present year in celebration of the seventy-fifth anniversary of the Royal Horticultural Society of Prussia. The display promises to be of great magnitude, as already nearly one-third more space is taken than sufficed for the great exhibition of 1890. We are informed that there are comparatively few Orchid entries, and that a good opportunity is afforded for British growers to distinguish themselves, the prize for 100 plants being 100 marks. The Directors would also like to see Cyclamens and other plants, also cut flowers, to compare with those of German gardeners. Schedules and information can be obtained from Professor Wittmark, General Secretary, 42, Invalidenstrasse, Berlin, who will be glad to give a hearty welcome to British amateurs and professional horticulturists.

— **HORTICULTURAL CLUB.**—The usual monthly dinner and conversazione took place at the rooms of the Club, Hotel Windsor, Victoria Street, Westminster, on Tuesday evening last. The chair was to have been taken by Sir J. D. T. Llewelyn, but business at the House of Commons prevented him from attending. Mr. Salmond, Clerk of the Gardeners' Company, was requested to take his place, and in a few appropriate words he thanked the members for the honour they had done him, the youngest member of the Club, in placing him in so honourable a position. There were also present Messrs. Geo. Paul, F. Rochford, James Walker, J. Assbee, T. Francis Rivers, F. Rivers, jun., C. E. Pearson, Geo. Bunyard, James H. Veitch, and the Secretary. A paper was read by Mr. T. Francis Rivers, entitled "Notes on Fruit," which displayed the long and intimate knowledge he had of the whole subject, especially in raising new varieties of fruit. This paper we hope to give in a future issue. It was followed by a very interesting discussion, in which most of the members present took part.

— **GARDENING APPOINTMENT.**—Mr. M. Roe, fruit foreman at Lockinge, has been appointed head gardener to Sir Albert Rollit, Bart., The Willows, Windsor.

— **THE ROYAL GARDENERS' ORPHAN FUND.**—It is announced that Sir J. Whittaker Ellis, Bart., has kindly consented to preside at the annual festival dinner of this charity, which is arranged to be held at the Hotel Cecil on Friday the 30th of April, 1897. The Executive Committee is anxious to give Sir Whittaker a hearty reception, and especially so during this eventful year, the sixtieth of the reign of our beloved Queen, and a large company is hoped for on the occasion.

— **ROYAL METEOROLOGICAL SOCIETY.**—A special exhibition of meteorological instruments in use in 1837 and in 1897 has been arranged in commemoration of the Diamond Jubilee of H.M. the Queen at the Institution of Civil Engineers, Great George Street, Westminster. It opened on Tuesday, March 16th, and will continue on view to Friday, 19th.

— **THE RECENT GALE.**—A very destructive gale raged through Sussex on the 3rd of March, which on account of the damage of trees is, I think, never likely to be forgotten; certainly it never will be on this estate, where it blew down gigantic Elms, Evergreen Oaks, and a very fine Yew tree about 60 feet high; and when I tell you that there are seventy-eight large trees down within a circle of 1000 yards from the house, the wreck can be imagined.—G. HART, *Buckingham, Shoreham*.

— **FEBRUARY WEATHER AT HODSOCK PRIORY, WORKSOP.**—Mean temperature, 41.4°. Maximum in the screen, 56.7° on the 23rd; minimum in the screen, 24.0° on the 12th; minimum on the grass, 13.9° on the 28th. Number of frosts, in the shade, ten; on the grass, eighteen. Sunshine, forty-one hours, or 15 per cent. of possible duration. Rainfall, 3.03 inches. Rain fell on sixteen days. Maximum fall, 1.14 inch on the 5th. Much rain and snow at the commencement, followed by floods; the rest of the month mild, with a good deal of wind near the close.—J. MALLENDER.

— **SUSSEX RAINFALL.**—The total rainfall at Abbots Leigh, Haywards Heath, for February was 3.02 inches, being 0.62 inch above the average. The heaviest fall was 0.59 inch on the 1st. Rain fell on fourteen days. The maximum temperature was 57° on the 20th; the minimum 27° on the 8th and 15th. Mean maximum, 48.06°; mean minimum, 33.21°. Mean temperature, 40.63°, which is 3.37° above the average. The latter part of month was mild, fairly dry, and pleasant. If it continue the season will be an early one. Rhubarb was gathered from the open ground on the 27th. March has come in cold and stormy, and at night on the 1st it was very wet.—R. I.

— **THE WEATHER LAST MONTH.**—February was wet until the 20th, when it became milder and drier, and continued so unto the end. The prevailing direction of the wind was W. on twenty-one days. Total rainfall, 3.06 inches, which is 1.4 inch above the average for the month; this fell on fourteen days, the greatest daily fall being 0.93 inch on the 5th. Barometer (corrected and reduced), highest reading, 30.611 inches at 9 A.M. on the 16th; lowest, 29.256 inches at 9 A.M. on the 2nd. Thermometers, highest in the shade, 56° on the 26th; lowest, 25° on the 28th. Mean of daily maxima, 45.82°; mean of daily minima, 36.10°. Mean temperature of the month, 40.96°; lowest on the grass, 20° on the 28th; highest in the sun, 102° on the 23rd; mean of the earth at 3 feet, 38.96°. Total sunshine, 49 hours 30 minutes. This is remarkable, being exactly the same amount as in January. There were eleven sunless days.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham*.

— **SHIRLEY GARDENERS' ASSOCIATION.**—The annual general meeting of above Society was held, on the 15th inst., in the Parish Room, Shirley, Southampton, and a good attendance of the members rewarded the efforts of the Committee. Vice-President W. F. Mayoss, Esq., presided in the unavoidable absence of the President. The report and balance-sheet were submitted to the meeting for approval. The report showed that there are about 140 members, which is an advance on last year, that there were thirteen meetings during the year, and an average attendance of forty-two. The balance-sheet showed a balance in favour of the Society of £4, and a sum of about £2 members' subscriptions still due, some of which came in during the meeting. The report and balance-sheet were unanimously adopted, and the election of officers and Committee for ensuing year next ensued, the President being unanimously re-elected, and the Committee increased from nine to fifteen. At the close of the business Mr. A. Dean, Lecturer in Horticulture S.C.C., gave a short address on "Horticultural Progress During the Victoria Era."

— **READING GARDENERS' SOCIETY.**—"Table Decorations" was the subject of an interesting paper read by Mr. Powell of Park Place Gardens, Henley-on-Thames, before the members of the Reading Gardeners' Mutual Improvement Association on Monday evening last in the Club Room, British Workman. Mr. C. B. Stevens, the President, presided over a large gathering of members.

— **COOL ROBBERY AT THE R.H.S.**—A cool robbery was perpetrated at the R.H.S. on Thursday, March 11th. The Council room was entered by a thief, who quietly and expeditiously appropriated the overcoat of the Assistant Secretary, Mr. J. Weathers, who was on the other side of the dividing curtain but heard nothing. The thief was considerate enough to leave a bundle of papers from one of the pockets behind him.

— **CORYLOPSIS SPICATA.**—On March 5th this interesting hardy Japanese shrub was in full flower. The flowers are primrose yellow with bright red anthers, which protrude from the mouth. They are produced eight or ten together in pendulous racemes along the whole of the previous year's growth. The individual flowers are separated by bracts the same colour as the flowers. Rather light soil and a sheltered position should be afforded this plant. Although perfectly hardy, sharp spring frosts sometimes injure the flowers.—W.

— **CINERARIAS AND PRIMULAS.**—Mr. Jas. Weeks, gardener to E. A. Sanders, Esq., Stoke House, Exeter, read a paper on the above subjects recently at the Guildhall, Exeter, to the members of the Devon and Exeter Gardeners' Association. *Cineraria cruenta*, he said, is a native of the Canary Islands, and was known in the year 1777. It had taken 120 years to bring the *Cineraria* to the perfection it had now attained. *C. cruenta* is said to be the parent of all the beautiful florists' varieties, which are most ornamental and useful for the decoration of the greenhouse and conservatory during the winter and spring. The *Primula* could be grown by anyone who had a greenhouse with just enough heat to keep out frost, and many of the species could be grown in the open with slight protection. Mr. Weeks then dealt with the best modes of culture.

— **THE WOODBRIDGE NURSERY.**—A well-known East Anglian nurseryman recently passed away in the person of Mr. John Woods of the Woodbridge Nursery. The deceased gentleman had attained the advanced age of eighty-four, and was greatly respected both for his knowledge of horticulture and for his high personal qualities. His nursery, which he confined chiefly to trees, shrubs, and seeds, was one of the best known in Suffolk, and had been carried on by himself and his father for over 100 years. In his prime Mr. Woods was one of the moving spirits in the Woodbridge Horticultural Society. His executors have disposed of the business to Mr. R. C. Notcutt, the *Chrysanthemum* grower of Broughton Road Nursery, Ipswich, who will carry on his existing business at Ipswich in conjunction with the Woodbridge Nursery.

— **DISEASED TOMATOES.**—In connection with what has lately appeared in the Journal in regard to disease in Tomatoes, I would like to point out that it is a great mistake to use any cow or horse manure, or liquid manure in their culture. Some years ago we experimented with some Tomatoes. One lot was planted in a bed where the soil was mixed with cow and horse manure, the other lot was planted in a bed of pure loam mixed with our Vine and plant manure. Disease appeared in the lot planted in the bed that had the cow and horse manure in it, but not a trace of disease was seen in the bed which had only loam and Thomson's manure. The beds were in the same house, and no more convincing proof of the folly of mixing cow or horse manure in soil to grow Tomatoes in could have been produced than the example I have given, to my mind at least.—JOHN THOMSON, *Clovenfords*.

— **WAKEFIELD PAXTON SOCIETY.**—Programme of meetings for the first quarter, session 1897:—March 20th, "Phases of Bird Life," illustrated by lantern slides, Mr. G. Parkin; March 27th, "Swaledale," illustrated by lantern slides, Mr. G. H. Goldsbrough. April 3rd, "Gardening in Relation to Amateurs," Mr. T. Pitts; April 10th, "Natural History Myth and Mystery," part 2, Major Norwood; April 17th, "A Vegetable Workshop," with diagrams, Mr. G. C. Rawden; April 24th, "The Daffodil," with specimens, Mr. J. Duncan Pearson, Chilwell Nurseries. May 1st, "How We Got Our Vegetables," Mr. B. Spencer, Bradford; May 8th, "Our Feathered Friends," Mr. W. Hudson; May 15th, "The Tulip," with specimens, Mr. J. L. Pickard, Leeds; May 22nd, "Basic Slag: Its Utilisation and Value to Gardeners," illustrated by lantern slides, Mr. Councillor Wigham; March 29th, special lecture, subject to be announced.—G. W. FALLAS, T. H. MOUNTAIN, *Hon. Secs.*

— **CINERARIAS AT THE DRILL HALL.**—Mr. Douglas writes:—"I am credited on page 199 as having been awarded a silver Banksian medal for my collection of *Cinerarias* exhibited at the meeting of the Royal Horticultural Society on March 9th. This is an error. My card states that a silver-gilt Banksian medal was awarded to the collection." [According to the official list which we have before us, Mr. Douglas was awarded a silver Banksian medal. The error is therefore not ours but the Society's.]

DEUTZIA GRACILIS.

AMONGST our beautiful spring-blooming greenhouse plants there are few more charming when in bloom, or more easily forced than *Deutzia gracilis*. It is a plant which no grower of flowering plants, and especially greenhouse plants, should be without, for it is an easy matter to have it in bloom from January to June if a sufficient quantity of plants are in hand to keep up a succession, and these have been well attended to the previous summer in the important matters of watering, feeding, and the ripening of the growths. *D. gracilis* is an easily managed plant, and responds readily to good treatment, and will even bear some neglect, but it is often called upon to stand too much, particularly when out of flower. Neglect of watering, or giving an insufficient quantity, is the most general error committed; inadequate feeding is the next; and when these two errors are combined the result is that the straight young shoots, which the plants have probably thrown up in abundance in the warm genial atmosphere of a greenhouse in early spring, are robbed of their vigour, and prevented storing up in a gradual lengthening, strengthening, and thickening addition to their parts the needful energy for their future work.

In commencing the cultivation of *D. gracilis* two methods may be pursued. One is to root cuttings and grow them on into plants, and the other is to obtain plants from a nursery, in the spring pot them, and force them into flower the same season. The former method is, however, I think, the better, and the plan of procedure must consist first of all in selecting suitable cuttings. These should be obtained from the base of vigorous plants, and ought to consist of such shoots or suckers which, if allowed to grow on the parent plant, would develop into flowering shoots another year. Their length should not be more than 4 inches or less than 2 inches. Cuttings like these will be sure to root and do well, giving a few flowers the first year—that is, the year following the rooting of the cuttings. Five cuttings may be placed in a 3-inch pot, placing four round the sides and one in the middle, using light soil composed of equal parts of fibry loam, sweet leaf soil, and clean white sand, surfacing the pots when filled, and gently shaken down with a shallow covering of sand.

This serves the double purpose of keeping the cuttings air-tight at their base, thus inducing quicker formation of roots, and as a good guide to the propagator in supplying water to the cuttings, for I have generally found it a safe and reliable rule only to sprinkle or water cuttings when the surface sand is becoming dry. When the cuttings have been inserted and gently watered in, plunge the pots in a mild hotbed, or any place where a slight bottom heat is maintained, covering them with a bell-glass, which should remain over them only until the cuttings are rooted, though it must occasionally be removed to remove superfluous moisture. The development of new leaves from the tops of the cuttings, as well as their erect appearance, will generally indicate that the formation of roots has commenced. The bell-glass may then be daily tilted a little, until it is finally removed.

Up to this stage the cuttings will scarcely have needed any water, except probably a few gentle sprinklings, but now that they have become plants developing roots and shoots, and absorbing more air, water will be needed oftener, and in gradually increasing quantity. When the pots are getting full of roots, or before being root-bound, or matted too much round the sides of the pots, the plants must be shifted into a size larger pot, which will, no doubt, be sufficient for the first season. Every encouragement must be given to induce a strong, vigorous, healthy growth, but no stimulants will be required during these early stages, or the possibility may be that the mixture in which it is growing will be rendered unhealthy, and growth thereby stopped.

Towards the end of the season, when roots are plentiful and the growths ripening, will be the most suitable time to apply a little stimulant, such as a little clear soot water or weak manure water of any kind. Topping the shoots must not be resorted to, but if flowers are not cared about the following spring, it is, perhaps, a little advantage to cut down the plants close to the soil and allow the whole energies of the plants to expend themselves in the production of new shoots for future flowering, instead of dividing these energies in the support of flowers as well as growth. But this cutting down should not be done until the leaves have fallen and the plant is at rest.

The summer treatment of the *Deutzia* is simple but important. The growth of the plant should, as far as possible, be made in the genial temperature of a greenhouse in a light position in the early spring months. When this is completed the plants may be transferred to a cold frame, giving air more and more every day until the lights are taken off altogether. The plants may then be plunged to the rims of the pots, or even below, in coal ashes in a position open to the sun, abundance of air, and plenty of wind, where the growths will be thoroughly ripened by the combined agency of these natural wood-ripeners. The plants should never suffer from want of water during hot weather, which every intelligent cultivator knows is a very important thing.—S.

DEATH OF DR. HOGG.

It is with sorrow more profound than can find expression here that the record of a death has to be inscribed in these pages, in which are largely reflected his life and his work—namely, the death of Dr. Robert Hogg. This took place at midnight of Sunday, March 14th, at his London residence.

Others of his friends and colleagues who have been associated with Dr. Hogg for very many years in various horticultural projects may perhaps more appropriately recount episodes in his career and describe traits in his character. The writer of these lines, however, who has been in almost daily contact with the deceased gentleman for more than twenty years, may be permitted to mournfully acknowledge the loss of one who was to him in very truth a "guide, philosopher, and friend," as he has been to many more during his long, busy, useful, and honourable career.

Though only a disjointed outline can be given of the life of the "dear old Doctor" as he was so commonly referred to, yet it may be said of him that no one has taken a larger share in the various movements having for their object the advancement of horticulture than he during the past fifty years, while it may also be safely said that the Goddesses of Flora and Pomona never had a more loyal subject.

Though learned in the sciences, at least, as they were taught in his earlier days, he was notably and essentially practical, not only in the art with which he was so long and intimately connected, but in the ordinary affairs of life, and his opinions on the various subjects on which he was consulted invariably carried great weight.

In "Men of the Time" we find that "Robert Hogg, LL.D., F.L.S., was born at Duns, N.B., in 1818, and was educated at a private school in his native town." He was the son of Mr. Robert Hogg of Cheeklaw and Bogan Green, Berwickshire, the head of the old firm of Hogg & Wood of Coldstream—famous among other things for forest trees, Leeks, as well as for agricultural and other seeds. The Doctor had no trade interest in the firm, its headship descending to his brother, Thomas Hogg, who died two years ago.

After a curriculum at the Edinburgh University the subject of this memoir came to London by coach in 1836, and was present at Her Majesty's coronation in 1837, a circumstance of which there is reason to believe the Queen has cognizance. The Doctor, who had a wonderful memory of past events, has more than once amusingly told the story of his entry into London. He was in charge of the late Mr. Charles Lawson, the "great" Charles Lawson as he was called. The object was presumably to gain a footing in the London seed or nursery trade. He was the guest of the late Mr. John Noble, who was then perhaps the chief representative of the great seed industry in the metropolis; but he had "no room" for the visitor in his business. Other "houses" were tried with a similar result. At last, calling with Mr. Lawson at Covent Garden, the then renowned fruit nurseryman, John Ronalds of Brentford, was met. "Ah," said Mr. Lawson, "you

are the very person I wanted to see. I have a young man here, the son of our friend Mr. Hogg of Coldstream, and you must take him." "Oh, well," was the reply, "if I must I must, but," and this with emphasis, "I shall only give him 15s. a week." The young Northerner was delighted, as he would have felt it a privilege to get into such a nursery without any remuneration. No doubt there are old friends of the Doctor who have heard him tell, in his quiet deliberate way, how he "started on 15s. a week, because," he would go on to say, with the merry twinkle in his eye, "I was not worth any more." Working diligently he gained a practical knowledge in nursery routine, and became an expert in most kinds of work connected with the raising of trees and the cultivation of fruit. It was during this period until 1845, when he entered into the business at Brompton, that Dr. Hogg, as the result of his travels in France, Belgium, and

Germany, first established those friendly relations with Continental botanists and horticulturists so often renewed in subsequent years by personal intercourse both in England and abroad.

Of penetrating rather than quick perceptions he, after investigating the matter of importations of hardy fruit from Holland and France (there was no American competition in those days); satisfying himself by observation of the prevailing negligence of fruit growing at home, as well as of the general ignorance pertaining to fruit, he resolved not only to make the subject a special study, but endeavoured by strong and effective articles in the press, including several in the early issues of the then *Cottage Gardener*, to arouse interest in and disseminate information on what he believed to be a matter of national importance.

The then young reformer also spent some time in the West of England, and gave to florists' flowers a large share of attention, especially, perhaps, Dahlias and Tulips. On the former he wrote a treatise, and in his latter days we could not imagine a more difficult

task than trying to convince the Doctor that the modern Dahlias were better than those of forty years ago. He would grant they were larger, but held that size was obtained at the expense of refinement. His old love of the Dahlia does not seem to have returned to him in the same way as did that of the florists' Tulip. These flowers had not changed. The old varieties remained with their characteristics unimpaired, but the varieties were hard to find; the natural persistence of the man, however, asserted itself, and a few years ago he resolved to form a collection.

No distance was then too great for the Doctor to travel to see collections in flower, and to there mark the varieties he wanted with the view to purchasing bulbs. He eventually obtained an excellent assortment, and his life was made the happier by their possession. His Tulips in May were his annual feast, enjoyed with a zest that was pleasant to see, though sometimes disappointing, as when fungus or eelworms feasted on his treasures. But even this imparted interest, for he set himself to discover methods to conquer the enemies, and always looked forward hopefully for the result of his endeavours.

His first Tulip prize was won when he was in the West, and he

FIG. 51.—DR. ROBERT HOGG AT THE AGE OF 56.

FIG. 52.—DR. ROBERT HOGG AT THE AGE OF 78.

never forgot it. Seeing the schedule of a Tulip show, and noting a laxity in the regulations, he decided to put a doubtful point to the test. He visited a collection of varieties so far advanced in flowering that the colours enabled him to choose the more promising. These he purchased, had the plants carefully dug up there and then, also as carefully planted on a site in his possession. Under the best attention they suffered little, and in the course of a few days he cut the blooms and won the first prize. Then came the contest as to his right, but it was decided in his favour. Though very markedly and emphatically a man of peace, when Dr. Hogg was face to face with a difficulty he was the reverse of easy to overcome.

Returning to the fruit, the young pioneer became a partner, by purchase, with Gray & Adams, in the long-famed Brompton Nursery at Kensington, in 1845; and the business of Gray, Adams, & Hogg was continued till the dissolution of the whole concern in 1851. This nursery was established in 1681, but the site became too valuable for growing fruit trees, and it is now occupied by the South Kensington Museum, Imperial Institute, with other National buildings; and it may be interesting to note that the Exhibition Road is on the site of the main thoroughfare that passed through the Brompton Nursery. The changes brought about since the Doctor's manhood seem little short of marvellous. The region of Belgravia, now covered with magnificent buildings, was during the same period devoted to market gardens, and there the Doctor, on the south side, built himself his London home.

Continuing to devote himself assiduously to his favourite study, Dr. Hogg produced "British Pomology" in 1851, a work in which is enumerated 940 Apples, and it was translated into German. It was in due time superseded by the "Fruit Manual," of which it formed the basis, this developing into a large work, which has passed through five editions, and has been several times translated. Its author had of recent years prepared a great amount of MS. for a sixth, which it was his intention to have produced, with assistance, had he been spared to regain health.

In the interval between the dissolution of the Brompton partnership and 1855 Dr. Hogg was associated with his father-in-law, whose premises occupied the site of what is now known as the Charing Cross Railway Station. His mind, however, was not of that unimaginative order which takes kindly to the calculating ways of business, and his leisure moments were ever devoted to the pursuit of botany and horticulture in some of their forms. These excursions led to his acquaintance with Mr. G. W. Johnson, a barrister, whose scientific leanings had prompted him to forsake the thorny paths of the law for horticulture, and who had established the *Cottage Gardener* in 1848. This paper was at first printed at Winchester, where Mr. Johnson lived, and published in Paternoster Row; but in August, 1860, the whole was removed to London. Mr. Johnson alludes to the advent of Dr. Hogg in the preface of the half-yearly volume in April of 1855 in his peculiarly genial way:—"Every seventh year is said to be an eventful year in the life of periodicals as well as of men. It has been an eventful year to us. The barque has partly changed owners, but the same hand is at the helm, with a friendly helmsman at his side to aid, to relieve, and to strengthen." The new helmsman was Dr. Hogg, and the two shipmates worked together like brothers till Mr. Johnson's retirement in 1879.

This gentleman died in 1886, and soon after that event Dr. Hogg became, by the purchase of his late colleague's share in the property, sole proprietor. But long before that (in 1861) the paper was invested with a new title. The change came about in this way: The *Cottage Gardener* grew beyond original anticipations, finding its way into most of the leading gardens in the kingdom. The character of its matter gradually changed accordingly, and the "Quarterly Review" said "the *Cottage Gardener* was for the occupiers of a cottage to which a double coach-house was attached." The proprietors took the hint, and changed the title to the *Journal of Horticulture*.

In 1858 he produced the "Vegetable Kingdom and its Products." This work must have involved great labour and research, as it contains an enumeration of 7000 genera and 4000 synonyms, representing about 100,000 species of plants. He was also the co-author with the late Mr. G. W. Johnson of the "Wild Flowers of Great Britain," published in eleven volumes.

Dr. Hogg was the originator of the British Pomological Society, which, with the co-operation of Sir Joseph Paxton (President), Mr. Spencer of Bowood, Mr. Thomas Rivers, and others, was founded

in 1854. He was first one of its Secretaries, and subsequently Vice-President. Monthly meetings were held for five years—in fact, until the Royal Horticultural Society became established at South Kensington. This great scheme was decided upon in 1859; but though the Doctor was so doubtful of its security as an investment as to "urge on all to whom money was a consideration to consider very seriously before sinking a penny in the concern," yet when it was finally adopted he accepted the position, and did all he could to make the great speculative project (in which so much money was ultimately lost) a success. With this object in view he took the initiative in transforming the Pomological Society into the Fruit Committee of the Royal Horticultural Society. Dr. Hogg was really the father of this the senior Committee of the Society, and the Floral Committee speedily followed.

Dr. Hogg was during the year 1865 zealously engaged with other earnest men in laying the foundations for the Great International Exhibition and Botanical Congress which was held in London the following year. The idea originated at a congress in Brussels in 1864, when the British representatives desired to invite their continental brethren to London, and a subscription was opened there and then. Amsterdam followed Brussels with a great gathering in 1865, and on the return of the British contingent it was determined to carry out the London proposal, and in a very short time £4200 was subscribed or guaranteed. Dr. Hogg was appointed General Secretary of this great project, and became intimately associated with Dr. Masters, who was Secretary of the Congress and foreign correspondent. The two Doctors who then worked together so amicably remained close and attached friends through all the following years till the elder was called away. Unfortunately this happened before a graceful tribute could be presented, the outcome of a happy thought and spontaneous endeavour of Dr. Masters.

In 1869 Dr. Hogg was appointed Official Commissioner of the Royal Horticultural Society to attend the great International Exhibition held at St. Petersburg during May of that year, his co-delegate being Mr. Andrew Murray, Sir Joseph Hooker representing British botany on the occasion. At the conclusion of the Botanical Congress the Emperor Alexander II. made known his wish to Dr. Hooker and Dr. Hogg to confer on them as a distinction for their services the Cross of the Order of St. Ann, but as the British Government did not permit its subjects to receive foreign distinctions His Majesty regretted he could not carry out his design. He commanded, however, the preparation of a malachite table and signet ring, which were sent to Dr. Hogg as a memento of the visit.

For thirty years and more Dr. Hogg gave to the Royal Horticultural Society loyal and even strenuous support, so long as he was convinced that a genuine horticultural policy was being pursued. When, however, he believed the reverse was the case he was a formidable antagonist, and thought nothing of driving all over London to pick up Fellows whose votes he could rely on for the purpose of turning out a Council whom he had reason to believe was out of sympathy with the objects for which the Society was established to promote. But for him and other earnest men the whole of the Chiswick Gardens would have been lost to the Society, and it was only by the most determined and persistent efforts that the establishment as it exists now was retained.

When the Society was remodelled in 1860, and the Committees formally established, Dr. Hogg was appointed Secretary of the Fruit, and Mr. Thomas Moore of the Floral Committee. The Council, as the Doctor wrote, "Was composed of men not chosen because of their social position only, but, combined with that, men of sound practical knowledge, sagacity and energy; and it was only with such men as its councillors that the Royal Horticultural Society could flourish." Prophetically true those words proved to be. In the course of time a non-horticultural pleasure-seeking Council of South Kensingtonians obtained power and brought matters to a crisis in 1875, adding a new debt of £5000 to an old one of £50,000. Lord Bury, the President, was then compelled to resign, and a Horticultural Council elected, including Dr. Hogg, who succeeded Mr. Lindsay as Secretary, and occupied the position during the most critical period of the Society's career. In recognition of the welcome change the chief nurserymen joined in making a great commemorative show, gratuitously, which was held on July 21st of the same year. It was composed of the finest and rarest plants, and their

artistic arrangement afforded a magnificent spectacle, giving a great impetus to extension of the now familiar classes of "groups of plants arranged for effect" at most exhibitions.

Dr. Hogg only retained his position as Honorary Secretary of the R.H.S. for a few years, and was succeeded by Major Mason, but continued on the Council till his resignation in 1889. Dr. Hogg remained a member of the Fruit Committee, and was thus closely connected with the Royal Horticultural Society for thirty-seven years. He watched with increasing pleasure the growing prosperity of the Society during his latter days, and had the fullest confidence in its Council and officials who have done so much for its advancement on true horticultural lines.

He provided for the Society the great collection of Pears which Mr. Barron grew and trained so well, many of the sturdy pyramids still remaining. Dr. Hogg also collected during one of his continental visits the present splendid collection of Figs at Chiswick, probably the finest assortment to be found in any garden in the world.

After the death of Mr. Johnson Dr. Hogg took a very small share in the editorial conduct of the Journal, and during recent years practically none. He had enough to do, and often more than enough, in the business department, and more than a year ago he relieved himself of all responsibility in favour of his son, Mr. R. Milligan Hogg, who then became the proprietor; but his father's honoured name remained till the last at the head of the *Journal* in the place it occupied for upwards of forty years, and all connected with their revered chief regret that it could not have continued for many years more.

When Dr. Hogg's actual retirement became known, which was some time after the event, his distinguished friend made his desire known in a confidential way to collect the portraits of such of Dr. Hogg's friends and associates as he could obtain (apart from the staff of the Journal) for presentation to him in the form of an album. It was to have been a surprise presentation, and the secret was so well kept that not one out of the hundred who so readily contributed photographs made the fact known. Dr. Masters, feeling the time was short, acted with all possible speed, but those in whose hands was placed the preparation of the album failed to complete it by the date expected, and which would have been just in time for acceptance by its intended recipient; but as the end was evidently approaching, and before the strong brain became clouded, the dear old Doctor was informed of what was in progress, and smiled in grateful recognition of an act as graceful as friends could bestow, and than which none could have been more deeply appreciated by a naturally warm heart. The memento will be treasured by the family in memory of the revered head.

All who enjoyed the intimacy and friendship of Dr. Hogg will admit his warm geniality. They will not soon forget the heartiness of his double handshake in taking and holding their hand in both of his; while all who have worked with him and under him will feel the impossibility of having a more kind and considerate colleague or chief. He has been a good friend to many by placing not a few gardeners in excellent situations, and assisting many more in sickness and adversity—not unfrequently in a way by which they could not know the source of the aid of which they were grateful recipients.

Dr. Hogg was an old supporter of the Gardeners' Royal Benevolent Institution. He became a subscriber to its funds in 1842, occupied the chair at the Anniversary Festival Dinner in 1876, and was for many years a Vice-President and Trustee. Mr. Ingram writes:—"The Institution always occupied a warm place in his heart, and it will greatly miss his interest and support."

When Dr. Hogg was well he spent all the time he could spare on his Sussex estate. He was rather fond of building. He first erected a large house, and formed and planted the garden. This, as his family dispersed, became too large, and he built himself another, forming another garden, planting collections of fruits, hardy trees, and shrubs, also hardy flowers. He was always his own architect and landscape gardener. He really built himself four considerable sized homes, and also found occupation in erecting and repairing cottages. This was his relaxation when in health; but eventually his strong constitution became undermined by oft recurring and increasingly serious attacks of gout. His recuperative powers became less and less, and for about three years he seemed to have been getting slowly but surely weaker. He was more or less an invalid during the whole of last year, and towards the end of it unable to leave his house.

When last seen by the writer a month ago in his library he was very feeble, and there was something in the long retention of the hand in both of his that seemed premonitory as he said, "Ah, Mr. Wright, if I *should* live to get out in the spring the sun and the flowers would do me good." Then a pause and penetrating glance, and in voice more firm, "But you know I have had a good innings. I have much to be thankful for, and *am* thankful I assure you, and shall be whenever I may go to sleep."

His look of resignation was impressive, and an affectionate "Good night and God bless you" closed this last interview with Dr. Hogg. The portrait (fig. 52) represents him much as he was then, age nearly seventy-nine; that in fig. 51 when he was in the matured prime of life, age about fifty-six.

His last days were as he and all his friends would wish—painless and calm, deepening to the end. This end seemed the embodiment of Richard Le Gallienne's lines, which appeared a few weeks prior to the memorable event:—

Soft sleep, sweet sleep; a little soothing psalm
Of slumber from Thy sanctuaries of calm.

* * * * *

Of all Thy good, great Lord, deep sleep is best.

About the time when many of our readers will be perusing this memoir the funeral cortege will be at the station of the London Necropolis Company, preparatory to leaving Waterloo by the train for Brookwood Cemetery, Woking, at 11.30 A.M.

As we are preparing for press we receive the following communications. Rev. H. H. D'Ombra writes:—"To what a large circle of earnest and sincere friends will the news come, filled with deepest regret that the valued and much-loved Editor of the *Journal of Horticulture*, Dr. Robert Hogg, has closed his honourable and useful life! Among the number of horticulturists of the present day there is no one whose name has been more before the horticultural public, and no one whose memory will be cherished with deeper feelings of affection and regard. Associated as I have been with him for the last five-and-thirty years, I long ago learned to respect him in the various ways in which I was brought into contact with him. A man full of wisdom, penetration, and courage, ever taking sound views of things happening around him, intercourse with him was always full of teaching and information, while his genial disposition always evinced itself in his kindness of expression and ready sympathy.

"All the readers of the Journal know full well how all his excellent qualities have impressed themselves on the paper over which he for so many years presided, and so in his private life it may well be believed that the ties of affection strongly knit him to those dear to him. Others will doubtless be willing to enter more fully into such details as may interest the public, but I could not forbear from giving my testimony to the memory of one whom I have always regarded as a sincere friend, and whose death leaves a blank which it will be impossible to fill."

Mr. L. Castle writes:—"By the lamented death of Dr. Hogg a noble mind is no longer at the service of the world. Many will hear the tidings with the heartfelt sorrow that attends the loss of a dear friend. A gentleman in spirit and deed, he set up a high standard of conduct even in the most ordinary everyday affairs. Extremely painstaking in his own work, one of his characteristics was that thoroughness which is so essential in life, and the possession of this quality by others was the surest passport to his regard. Such a man must leave his impress for good upon his contemporaries, helping to mould the thoughts and acts of many. Friends and associates who fully realise the loss sustained have still the great satisfaction of looking back upon 'a life well spent.' Long and varied experience, keen and critical observation, aided by a retentive memory, had furnished the Doctor with an encyclopædic knowledge, especially on horticultural matters, which those who have ever had the privilege of listening to his reminiscences could duly appreciate. The powers of his mind are well shown in his works; and the 'Fruit Manual,' which is a monumental work of close observation, with careful analysis and classification, is without a rival in the English language, and with it the name of Dr. Robert Hogg will go down to posterity as the foremost authority on fruits of the Victorian age."

LE CHRYSANTHÈME À LA GRANDE FLEUR.

WE noticed this excellent French work when the first edition was published twelve months ago. A second issue has quite recently appeared, and in every way equals the previous one, for the printing and illustrations are in the same style and the contents are the same, although to an extent augmented by the inclusion of additional matter.

SHEFFIELD CHRYSANTHEMUM SOCIETY.

THE usual monthly meeting of this Society was held in the Society's rooms on the 10th inst., when a good number of members attended to hear a paper on the "Pelargonium," by Mr. J. Dixon. Mr. F. W. Littlewood presided. The exhibits for the month were pot plants in bloom for professional members, and cut blooms in the amateurs' section. A few days prior to this meeting the Society held its annual concert, which was followed by dancing. The fixture was arranged some years ago to enable the wives and families of the members to have one evening in the year in which they could show their appreciation of the Society, and enjoy a social evening together.—J. H. S.

A TOUR ABROAD BY A HAPPY TRIO.

(Concluded from page 155.)

AT Sheffield, on Saturday at Ghent, on Tuesday at Paris, and on Wednesday travelling north as fast as express could carry him to Edinburgh, or, in other words, finding himself in five different countries for Chrysanthemum purposes in the short space of about a week. That was the experience of Mr. H. J. Jones. His first visit to the Paris Chrysanthemum show impressed him to such an extent that in his heart he would much rather have remained with us than gone on his way alone to the land of cakes and ale.

We turned our footsteps towards the show the second day. Long before midday the President of the Republic, Mons. Felix Faure, came again to visit the display, and was much more fortunate than on the previous afternoon, when the crowd was so dense. Almost everybody of note in the French Chrysanthemum world was present, and it was a very pleasing part of the day's work to shake hands and chat pleasantly, if only for a few moments, with many men who were hitherto known to us only by name.

It is worthy of note that about twelve months previously the National Horticultural Society of France organised a special Committee to watch over the interests of the Chrysanthemum, and that the Committee has accomplished much useful work. The broadness of scope will be understood when I say that this Committee is not confined to members of the Society, but that outsiders who are distinguished in any way for their knowledge of Chrysanthemum matters are admitted as associated members without payment of any subscription. A periodical publication is issued at intervals containing reports of the work of the Committee and circulated gratis among the members, so that those living at a distance may know what is being done. Of this Chrysanthemum Committee Mons. Aug. Nonin is the President, and an enthusiastic grower of the flower. He was a large exhibitor, and was the winner of the Grand Prix d'Honneur, a work of art offered by the President of the Republic for a most interesting group arranged with three semicircular sides in one of the rooms.

The Paris Show may be considered a thoroughly representative one of French Chrysanthemum growers, for exhibitors were not confined to Paris and the environs, but came from all parts of France. A very full display of new seedlings as yet undistributed was made, and these were dealt with by one section of the jury specially charged with the work of examining them and granting certificates to those of exceptional merit. The following day we also spent in the Show, completing our notes and making more new acquaintances. In the evening we were due to dine with Mons. Martinet, the editor of the "Jardin," at his home on the Boulevard St. Germain, where in company of himself, Madame Martinet, Mons. Ernest Bergman, and Mons. Dubois, we passed one of the pleasantest evenings during our stay abroad. The kind hospitality of this genial French journalist and his charming wife, combined with the bright conversational powers of Mons. Ernest Bergman, will long remain in our memory as one of the many enjoyable reminiscences of our journey.

Our stay was now over so far as Paris was concerned, and we decided to push on the following morning to Amiens. The rain when we left Paris at midday was descending in torrents, but within a short time of our departure it ceased, and we completed the journey beneath a beautiful blue sky and bright sunshine flooding the landscape all along the line of route. Doing this part of the journey by daylight was almost the first since we left England, and it was pleasant in the late autumn to see the well wooded country with the trees, mostly Silver Birch, Oaks, Beech and Poplars, still clad with foliage of golden bronze and russet hue. Women were working in the fields, ploughing in several cases being accomplished with the aid of oxen. The ground was beautifully undulating and interspersed with many a winding stream, and here and there a château in the distance.

On arriving at Amiens our first business was to secure our rooms, and

then make inquiries as to the Chrysanthemum show, which was advertised to open on the following day. The Hôtel de Ville, we learnt, was the place in which it was to be held, and so away we went to learn what we could as to the hour of opening. We found the Secretary and others all busy at work, and, explaining the object of our visit, were given every facility and a free pass for the following morning. There was but little variation between that and the one at Paris so far as the leading features were concerned, although, of course, it was on a much smaller scale, and the average of cultivation was not so high. The show was held in three separate rooms on an upper floor, and the exhibits consisted largely of groups of pot plants, although cut blooms were duly provided for.

Mons. Catelain, the Vice-President, Mons. Emil Roussel set up some good groups, and the varieties shown were on the whole fairly well known to us, although there certainly appeared to be a large number among them of only local repute. Cut blooms were staged in good form by Mons. Anatole Cordonnier. Most of the other exhibits were much smaller in size, and rather rough in finish.

Our mission was now over, and our way lay homeward. Before leaving Amiens we strolled round the town, and of course paid a visit to the Cathedral, one of the most imposing in Europe, and built about 600 years ago. We obtained a glimpse of several other large buildings, the Museum, Palais de Justice, the Library, Hospital, and the like, and then caught the Calais express at half-past one. Another beautiful day, almost summer-like; but as we got further north the sky clouded over, and when we reached Calais it was leaden in colour, and a fine drizzle falling. This part of the country is flatter and of less interest. We passed through many a quaint old village, and noticed that large numbers of the cottagers were bee-keepers. Heaps of Beetroot for sugar lined the railroad in some places for a great distance, and as we got further cattle and sheep were grazing in large numbers, and the well-wooded, hilly country looked as prosperous and as well looked after as could be wished.

Once again we were on board the steamer, and after a short passage across the Channel found ourselves in old England, with nothing but pleasant memories of the many kindnesses that we had received from our continental friends wherever we had been.—C. HARMAN PAYNE.

THE YOUNG GARDENERS' DOMAIN.

NOTES ON VINES — THRIPS AND RHEUMATICS.

I THINK "Student" has mistaken my meaning. We always damp down with liquid manure, as ammonia from it helps to keep Vines free from red spider and thrips. I did not wish in my former article on Vines to convey the meaning that the small amount of ammonia from damping down with liquid manure would kill red spider, is used as a preventive, and it is also good for Vine foliage I believe.

No, "Student;" I know too much about red spider and thrips to think you could clear a house of them so easily. I used to think constant syringing would kill thrips on Peach trees, or, if not, according to Miss Ormerod, they would take rheumatics from the damp and die. Last year I saw a house of Peach and Nectarine trees in a bad state with thrips, and too open in the roof for fumigating. Syringing was resorted to three and often four times a day, and the floor kept constantly damp, yet the thrips increased, and few died from rheumatism I think.

Bending Vines down before starting to check the flow of sap to the top buds, and strengthen the bottom ones, is another old belief exploded, as so many are in gardening, as in everyday life. Exploded fallacies is a subject on which much could be written and many anecdotes related. Well do I remember the look of astonishment on the face of a gardener of the old school who saw me watering Ferns with liquid manure, his views and those practised in his young days being "give no manure to plants potted partly or wholly in peat."

Surely there must be a mistake in the editorial footnote to the article by "H. H." on "Vine Pruning," in the issue of January 14th, where it is written Barbarossa is a pale red or grizzly coloured Grape. This and Gros Guillaume may, like Cooper's Black and Gros Maroc, Bowood Muscat and Muscat of Alexandria, be too much alike in some places to be shown as distinct Grapes. Gros Guillaume is a black Grape, and carries a fine bloom when well finished. The late Mr. W. Thomson of Clovenfords said it was a noble looking and valuable Grape, a good keeper; when finished jet black. The "Fruit Growers' Guide" gives the colour as deep purplish black, and carries a fine bloom.—W. T., Ireland.

[Both the late Mr. Thomson and the "Fruit Growers' Guide" are correct in the references to Gros Guillaume, but the remarks would be quite wrong if applied to Barbarossa. Dr. Hogg has recorded in his "Fruit Manual":—"The Grape which has been grown in this country for some years under the name of Barbarossa is a totally different variety. Its correct name is Gros Guillaume, and it is black; the Barbarossa is, as its name implies, a rose coloured or grizzly Grape." "W. T." is not fortunate in his first tilt with the Editor, who wishes him better luck next time. Will he and all correspondents who refer to published articles oblige by always quoting the pages on which they appear?]

POLYANTHUSES AND PRIMROSES.

THESE spring flowers at this time of the year give a bright appearance to beds and borders. Plants should be raised from seed annually, but not treated as annuals beyond the annual sowing of seed.

By sowing the seed as soon as it is well ripened, and pricking off the

seedlings into frames shaded from the bright sun, they are generally strong enough to plant out the same autumn. The seed may also be sown early in the spring in drills about 6 inches apart on a south border, and when the plants are large enough planted direct from the seed bed.

The plants usually flower well the first spring, but far better the second, when the plants seem to be at their best, for from that time, whether lifted or replanted, they almost always begin to decay, especially in hot and parching weather; but when the summer is cool and moist the plants stand fairly well. The decay may sometimes be avoided by taking up the old plants, pulling each crown off singly, and planting in fresh soil; but it is far the simpler plan to raise a fresh batch each season.—J. B., *Eastnor Castle Gardens*.

VINES AT PENRHYN.

I HAVE read with considerable interest Mr. Craven's note on Vine pruning at Penrhyn. Having often heard of the grand Grapes produced on these old Vines (faggots, as he calls them), I venture to ask a few questions. He says Mr. Speed is constantly working in young wood from bottom to top—a sort of compromise between long rod and spur pruning. Do I understand Mr. Craven to say that several short canes are run up annually at intervals of the forty-year-old rods, fruited, and cut away again? I would also ask if the borders in which these veterans are growing have been renewed during that time, and if the vigour and longevity of the Vines is not due more to the new borders than to the system of pruning? Mr. Craven truly remarks there is food for reflection, and I feel I shall not have written my first Journal note in vain if we get an answer from such experts as Messrs. Speed and Craven on Vine culture.—STONE, *Warrilow*.

[Written very well, too. It is better to write briefly and well, than lengthily, but indifferently.]

GLOXINIAS.

HAVING read "Youngster's," and "W. P.'s" treatment of Gloxinias, I think "W. P." is rather hard on the former. I quite agree with "Youngster" in moving the seedlings as early as possible, as otherwise they are liable to damp off, and surely "W. P." must be dreaming when he says Gloxinias will not rest in a cool greenhouse from which frost is excluded. I find the corms are more sound, and start into growth more strongly when kept in a cool house, and do not shrivel as they do when kept while resting in a high temperature. They do well when started in a vinery at a temperature of 50°, and grow sturdily. As they increase in growth we remove the plants to a fernery with a temperature of 60°, where they bloom abundantly.—GLOX.

WHILE thanking "W. P." for so kindly criticising my article on Gloxinias, which appeared on page 144 of this Journal, I will venture to say a few words in support of the method I recommended. Firstly he remarks, "Youngster" seems inclined to deplore the fact that Gloxinias are not largely grown. In answer to this I shall point out that I inferred they were not so largely grown as their easy culture and great usefulness merit. They are generally grown, but not largely in the majority of places. As regards the early pricking off much may be said in favour of the system. Perhaps "W. P." has not paid a visit to the nursery of a leading Begonia grower not a hundred miles from Forest Hill, or to one where Gloxinias are raised annually by tens of thousands in the early spring. If he has he will have seen lads just left school standing at benches by the half dozen, busily engaged with prong in one hand and pointed stick in the other pricking off the seedlings in exactly the same manner as I have described. Moreover, what tender-rooted seedling does not benefit by an early removal from the seed pans, especially those which are tuberous or bulbous rooted?

Again, "W. P." writes, a cool greenhouse would not be a suitable place in which to store the corms during the resting period. What does he call a cool greenhouse? My idea of such is one which is kept at say 50° at night from November to March; if kept in too high a temperature watering will often have to be resorted to to prevent the corms shrivelling. I have seen them wintered safely in a late vinery where just enough heat was maintained to exclude frost, and that with good results.

"W. P." may also observe that I did not recommend starting the corms in a temperature of 50°; what I said was it should not fall below that at night. The temperature he advises would in my opinion be a very suitable one in which to start them.

As regards compost, "W. P." has undoubtedly had good results from plants grown in his mixture, so also have I from plants grown in mine. Opinions differ, but I think if twelve gardeners were asked to give their opinion as to what soil to use for potting Gloxinias, six would probably favour one and a half dozen the other. "W. P." also says soot is best used in liquid form. True; but it is a well-known fact that soot is such an excellent purifier that I am still of opinion that a small quantity mixed with the compost cannot do otherwise than benefit the plants if used in a judicious and careful manner.

As regards numbers "W. P." says we grow them by the hundred. I may add that our numbers reach almost into thousands. With all due respect to "W. P." I venture to think that after he has carefully read my article once or twice more, he will not be quite so much surprised after all at the method of culture recommended by—YOUNGSTER.

PRUNING.

I READ with much interest "Sylva's" article on "Tree Pruning," page 151. It is to be feared his words are very true as regards young gardeners not studying arboriculture. It is hoped we shall take his gentle reminder in the right light, not as criticism, but advice. We must make his subject a study, and continue until we master it. Given a young man in a good garden, where both forest trees and Coniferae are well cared for, what scope there is for instructive observation. We may see an isolated specimen growing in all its natural beauty; what an object lesson it is!

Let us pass onwards and out of the pleasure grounds, and take a walk along a country roadside; we may then find a tree of the same variety lopped beyond recognition. Again, we may see a clump of trees, each one perfect, as it were, in its own symmetry. Has it ever occurred to us what care was bestowed or what protection given when young by some perhaps forgotten fostering hand, or with what foresight each one was pruned and thinned? I think not, at least to the majority of us. Do not let it be thought I want to launch as a critic; on the contrary, "Sylva" has made me feel my own weakness. His words have struck very deep; may they do so in others.

FIG. 53.—CYPRIPEDIUM LATHAMIANUM. (See page 226.)

Young fellow gardeners of the domain, and those who may read these few words, let us make this subject one of our greatest aims; let us try and place ourselves even beyond the gentle hint of one-sidedness. Leave the glass houses for a time, pass through all the grades of our profession onwards and upwards to the top. We may perhaps develop false leaders in our course, as the trees spoken of by "Sylva;" let us at least sever them before they go too far. We might notice the distances of various trees, their respective heights and situations, so that in time to come, if called upon to do such work, we shall benefit by the lessons thus afforded.—SEMPER.

CARNATIONS.

THESE flowers are now in the front rank. They are good for cutting and last a long time in water; their long stems make them very useful for vases, while their fragrance is second to none. If grown in beds the hoe should be run through the surface frequently, as it prevents weeds and keeps the surface of soil from cracking in dry weather. When the flower stems appear they should be neatly staked; some prefer wires because they are not so conspicuous.

About the first week in August the "grass" ought to be layered; the layers will root in about a month. In October the plants may be carefully taken off and transplanted in new beds, leaving room between the plants for layering the following year. Those not required should be preserved to fill any vacancies that may occur in the spring.

In planting be very careful not to bury any grass, and press the soil firmly round each plant. Good loam suits them best. A sprinkling of soot may be used now and again with advantage.—DIANTHUS.

FRUIT FORCING.

Cucumbers.—Winter fruiterers will require frequent attention for removing exhausted growths and bad leaves, thinning where too crowded in order to encourage a free growth and a successional supply of clean, straight fruit. Stop the bearing parts two joints beyond the fruit, and secure the growths to the trellis. It will much invigorate the plants by removing a little of the surface soil where it can be done without injuring the roots, supplying a top-dressing of turfy loam with a sprinkling of approved fertiliser. When the roots are active in the top-dressing sprinkle a few sweetened horse droppings on the bed occasionally, with a light dusting of soot—a small handful per square yard—alternating with the fertiliser so as to get plenty of vigour in the plants and colour in the fruit. If that is not enough, and the plants crop heavily, supply liquid manure of a nitrogenous nature, such as nitrate of soda, at the rate of half an ounce to a gallon of water, always having the water or liquid equal in temperature to that of the mean of the house.

Young plants will need more soil, adding to the hillocks or ridges as the roots protrude, always having it warmed and in a properly moist condition. Maintain a night temperature of 65° to 70° when mild, 70° to 75° by day from fire heat, keeping through the day at 80° to 90° from sun heat, closing early in the afternoon with abundance of moisture so as to run up to 95° or 100° on bright days, securing a steady bottom heat of 80°.

Manure-heated pits and frames which have been set to work some weeks will require good linings. This is best effected by removing as much of the outside of the beds as can be spared, and if the heat has not much declined it will suffice to line one half of the bed at once, deferring the other half until the heat is again on the decline. To be effective the lining should be 2 feet wide, for thin linings are soon spent, and sooner require renewal. Look carefully to the frame after the heat generates in the lining to see that there is no accumulation of rank steam, preventing it by a little ventilation, especially when the sun shines. Add more soil as the roots spread on the surface, taking care to have it warmed. Attend to training and pegging the shoots, not overcrowding them; pinch the leaders a foot from the sides of the frame, and stop the laterals one or two joints beyond the fruit. In watering do not wet the foliage more than can be helped, as it is quite soft and easily scorched. A good night covering will be necessary to maintain a temperature of 65° to 70°, though it may fall lower on cold nights. Admit a little air at 75°, allowing the temperature to rise to 85° or 90°, closing before it falls below 85°, and if it rise to 90° or more the day's work will be better, and a good heat stored for the night. The night coverings should be put on by the time the sun is off the lights, say about five o'clock in severe weather, never delaying beyond six o'clock in the afternoon at this time of the year.

Figs.—*Earliest Forced Trees in Pots.*—The very early varieties, such as St. John's and Early Violet, that were started in gentle bottom heat by the middle of November, are now showing signs of taking the last swelling for ripening. Pingo de Mel, Brown Turkey, and White Marseilles, however, are still stationary. They must not be hurried, as this is the most critical time in Fig culture, checks of any kind causing the fruit to fall, and this must be carefully guarded against by maintaining an equable temperature, making the most of fine days for giving air, and closing early so as to secure safe advancement. After the fruit gives indications of ripening water must be withheld; yet, though less water at the roots is necessary, there must not be anything like dryness in the soil. Until the fruit changes for ripening the trees must be well supplied with liquid manure, giving the whole rooting area a thorough supply, and to trees safely passed the flowering stage a thorough soaking of water a few degrees warmer than the bed acts like a charm on Fig-tree roots, especially when a light mulching is supplied of sweetened lumpy manure, as this absorbs moisture when the trees are syringed, and the changes it undergoes attract the roots, whilst a genial vapour is given off highly favourable to the foliage. Syringe twice on fine days, once a day when the weather is dull, always giving the second syringing in time for the foliage to become fairly dry before night. Maintain a night temperature of 65° in mild weather, 70° to 75° by day, and with sun secure a heat ranging from 75° to 85°, closing early so as to raise it to 90° or more, as Figs swell best with abundance of heat, moisture, and light; full exposure to sunshine being absolutely essential to secure high quality. Stop side shoots at the fourth or fifth leaf, not allowing them to become crowded; then, where needed, train terminals forward where space remains unfilled, and it can be done without shading the fruit.

Early Forced Planted-out Trees.—Where the roots are confined to narrow limits, as they should be, use sweet rather lumpy material as top-dressing. This should be moistened as often as it becomes dry, as that is necessary for decay and the evolving of manurial elements, especially ammonia, which in minute quantities and in regular supply has a marked effect on the health of the trees. Syringe the trees thoroughly twice a day, or damp the paths and other surfaces frequently on dull days. Keep the temperature at 60° to 65° at night in mild weather, 5° less on frosty nights, ventilating from 70°, and keeping through the day between 75° and 85° from sun heat, attending to air-giving early, closing with a brisk heat about three o'clock in the

afternoon or earlier when cloudy. The growth is rapid, therefore give frequent attention to stopping side shoots at the fifth or sixth leaf, as these give the best results in the second crop, but avoid too many, for Figs are produced in proportion to the light received; hence where two shoots or more appear rub off all but one, retaining those only that can have full exposure to light, otherwise they will not be sturdy and fruitful. Train terminals and successional growth to replace those reaching the limits and to be cut out after fruiting in their full length.

Late Houses.—Very fine crops of Figs are grown in houses with a south aspect, even when unheated. The trees should be trained down rather than up the roof, as the fruits always face the sun, and are sturdy and fruitful in consequence. Brunswick and Negro Largo, both strong growers and bearing grand fruit, do well under such treatment, planting them at the back of the house, training the trees with single stems up the back wall of a lean-to and the fruiting branches disposed down the roof on a trellis about 16 inches from the glass. In that form it is questionable if there are two finer Figs for cool houses, Black Genoa also affording enormous fruit of highest quality. For general purposes Brown Turkey stands unrivalled, White Marseilles being a fine, large, roundish fruit, and freely produced where there is room. Grizzly Bourjassote is the most constant for delicious flavour, and ought to have heat. For late supplies Negro Largo, Nabian, and Agen are excellent, but these must have heat to ripen the late fruits perfectly. The grand secret in growing Figs is plenty of light and heat, and the principal points in their culture consist in keeping the growths thin, their points always facing the light, and when growing afford generous treatment.

Melons.—To secure a good set of fruit on the earliest plants it is necessary to keep the bottom heat at 80° to 85°, with sufficient moisture in the soil to prevent flagging. Activity at the roots is essential to the fruit swelling, and will not induce grossness unless the soil is surcharged with water; it ought to incline to dryness, so as to arrest growth, which centres the forces on reproduction. A rather dry warm air favours the production of pollen, affording a little air constantly to prevent the deposition of moisture on the flowers. Fertilise the blossoms every day when fully expanded, and stop the growths one joint beyond the fruits. When these commence swelling remove all flowers, earthing the roots by placing warm soil against the sides of the hillocks or ridges, pressing it firmly. Apply water as required, avoid a soddened condition of the soil, sprinkle the floors in the morning and evening, lightly syringing the plants at closing time when the days are bright.

Melons, to swell well, require a night temperature of 65°, or a little more in mild weather, 70° to 75° by day artificially, 80° to 90° from sun heat, closing early in the afternoon, so as to raise to 90° or 95°, even 100° doing no harm provided the atmosphere is moist. If a succession of fruit is wanted in the same house some of the plants should be deprived of the flowers that appear on the first laterals; stopping these at the second joint will cause the sub-laterals to show fruit, which will be several days later and the fruit finer, because the plants are stronger, but quality depends upon the solidification of the growths—their exposure to light and steady supplies of nutrition. Place supports to the fruits in due course to relieve the plants of the weight; pieces of ½-inch deal 6 or 7 inches square, suspended in a sloping direction by four pieces of wire from the trellis answer well, or squares of garden netting fastened to the trellis by four pieces of string may be used. Make additional plantings, press the soil around each plant, shading for a few days if the sun be powerful for a couple of hours in the middle of the day, discontinuing it when the plants become established. Young plants should be grown near the glass in order to keep them sturdy. Sow for succession.

Plants in Pits and Frames.—These require similar treatment to Cucumbers on lining the beds, adding fresh soil as the growth advances and covering the lights at night. Train and regulate the shoots, removing every alternate lateral, and apply water only to maintain a steady growth. Seedlings may be potted singly as soon as they show the second leaves. Seed should be sown to furnish plants for pits and frames as they become cleared of forced Potatoes and Radishes, about five weeks being necessary to secure strong plants for placing out before they become root-bound.

THE FLOWER GARDEN.

Work in Shrubberies.—Shrubberies generally ought now to be put into good order for the season. In many instances the older ones will be much improved by having some of the ugliest overgrown Laurels sawn down to near the ground, others merely require to have some of the branches freely shortened back, while all pay for timely attention in the way of pegging down branches of Laurels, Rhododendrons, and Aucubas especially wherever the fronts are badly furnished. Where extra large Laurels are cut down it will in some cases be necessary to plant a few young bushes, and these will grow and fill the space in conjunction with the branches from old stumps much more regularly than before. Newly formed shrubberies are usually planted much more thickly than is ultimately good for the trees and bushes. Thinning-out ought, therefore, to be freely resorted to, transplanting a portion of the shrubs to where there are more needed being the wisest course to pursue. This work may be continued for another six weeks, always providing it is done well. Nor should pruning be neglected in the case of young shrubberies, as, with the aid of a knife used just now, many plants can be kept within bounds and of better form than if allowed to grow at will. All open shrubberies especially ought to be lightly forked or skimmed over with a spade, this burying much rubbish and presenting a far neater appearance.

Climbers.—The commoner and more vigorous kinds, notably Ivies and Japanese Honeysuckle, are apt to overgrow the rest, and both are

objectionable when in a rough state. When they get too large or coarse it is a good plan to cut them hard back to the wall, or, better still, down to near the ground, the young growths that soon follow being far more ornamental in appearance. Ugly overgrown plants of *Crataegus pyracantha* might also be cut down with advantage, young spreading branches neatly laid in to a sunny wall invariably flowering and fruiting freely. Thickets of Clematises must always be prevented. Those that flower from young growths formed last summer should be only thinned out and lightly shortened back, but the late summer and autumn flowering species, including the well-known *C. Jackmanni*, ought to be freely shortened, the aim being to secure as many strong back growths as possible. These will flower strongly. All lateral growths on *Jasminums* to be spurred back to the old wood, the common sweet-scented white kind flowering on the young shoots, while *J. nudiflorum* will form fresh wood for flowering next winter. *Chimonanthus fragrans*, *Pyrus japonica*, *Pomegranate*, *Myrtles*, and *Garrya elliptica* to have all straggling branches shortened back and leading growths laid in. *Euonymuses* to be similarly treated. *Magnolias* require no pruning, but must be firmly fastened to the walls. *Wistaria sinensis* to be treated similarly to Pears, the flowers being most freely produced by short spurs.

Manuring Roses.—If starved at the roots, Roses need not be expected to grow strongly or produce good solid blooms. They are often located where mulchings of manure would prove unsightly, but even this difficulty can be overcome. The simplest and best plan in most cases would be to carefully remove the soil down to the roots of the plants, returning this after a liberal dressing of manure has been given. The manure being thus covered with soil is well hid from view, that is if the birds can be kept off. It is within easy reach of the roots, and retains moisture much longer than it does when spread on the surface. Those Roses growing against sunny walls stand in especial need of a heavy mulching of manure, and may with advantage also frequently receive liberal supplies of water and liquid manure from the present time and onwards. The least that can be done for those in the open is to lightly work in a dressing of half-decayed manure, this being done directly after pruning is completed.

THE KITCHEN GARDEN.

Celery.—Celery seed is generally sown too thickly, and there must be no undue delay in pricking out seedlings. After the plants are in "rough leaf" and have been exposed to the light and sunshine long enough to make them sturdy, prick them out 2 inches apart in boxes of fine moderately rich soil, and place in gentle heat. Shade from bright sunshine for a week, subsequently raising them to a light position. From these boxes they ought to be transplanted to beds of rich soil on a mild hotbed. If wanted extra good for exhibition purposes in August a few score could be moved out of the boxes, before they press against each other, into 6-inch pots, growing them on shelves in gentle heat till they are nearly large enough for the open. Prepare beds on or even above the level specially for these extra strong early plants. They will grow more rapidly in these than they will in colder trenches, blanching being effected by means of paper wraps. Sow seed now for the main crop. White varieties are the first fit for use, but if the red or pink stalked sorts are slower in blanching they are usually the most solid and the best keepers.

Celeriac.—Those who desire to have a supply of Turnip-like roots for flavouring soups or for use as a vegetable should sow seeds of Celeriac now. Treat the seed and the resulting plants in every respect similarly to ordinary Celery, eventually planting out on the level, roots, not blanched stalks, being wanted. If the ground intended for early Cauliflowers is well manured that crop will leave plenty behind for Celeriac, and will be cleared off in time for the latter to be planted out in close succession without any further manuring or digging being required.

Kidney Beans.—During the hot days of April and May Kidney Beans succeed none too well in pots under the most favourable conditions, and may easily prove unprofitable. Where a close succession is imperative the sowings from this date ought to be in deep narrow boxes, such as may be arranged on walls in forcing houses or on back shelves. It will be found that the soil in these boxes will not dry nearly so quickly as it is liable to do in pots, and if the plants are not crowded they will grow vigorously. Red spider is usually rampant on pot plants, but is more easily kept under with the syringe in the case of plants in boxes. Canadian Wonder or some other equally robust heavy-cropping variety should be sown in rich soil, thinning out the plants severely and feeding well at the roots when they are commencing to crop. Pits and frames are of good service in keeping up the supply of Beans. Raise successional plants in small pots, and plant out in close succession to early Potatoes. Dispose them thinly in rows 15 inches or rather more apart, and keep well supplied with water.

Peas.—Birds and slugs have greatly disfigured and crippled many of the early Peas turned out of pots and not protected. If lines of strong cotton strained over and about the rows are not sufficient protection galvanised wire netting guards ought to be used, taking care to remove these before the plants grow up through them. Peas transplant readily, and if there are many gaps in the rows fill them up. Placing stakes to the plants when first put out is recommended, as they afford a certain amount of protection.

More seed of a good early variety, and with this an approved second early sort, should now be sown, that is directly the ground is in a fit condition for the purpose, the rows to be as far apart as the known height of the varieties and the seed sown thinly. If the market growers' plan of growing Peas without stakes is tried sow the seed thinly in a narrower drill than is desirable in the case of rows that are to be staked,

and in this instance the lines may be from 30 inches to 3 feet apart. Medium height to tall varieties are all suitable for this method of culture, as they do not form much superfluous haulm. The comparatively mild winter has been favourable to the preservation of mice and other garden foes, and Pea seed is particularly enticing to the former. Coat the seed with red lead prior to sowing, or introduce a cat into the garden and let it work for its living.

Lettuce.—Prick out abundance of plants that have been raised under glass. One sowing treated in that way may be made to yield a long succession of hearts in May and June. Some may be forwarded in boxes of good soil, and planted out on warm borders or sunny open positions, and the rest be pricked out in nursery beds, where they can be protected from cold winds and slugs, eventually transplanting the greater portion to well-prepared sites. Sow more seed of Cos and Cabbage varieties thinly in boxes or unheated frames, and also on a warm border. If the latter is a success the plants raised in boxes can be left to grow up thickly with a view to having a supply of tender young plants for cutting and use as a salading.

Seakale.—If the thongs or coarse roots broken off when lifting the plants for forcing have been saved, but are not prepared for planting out in April, it should be done at once. Cut them into short lengths of about 4 inches, taking off a thin slice from the smaller end, and dibble them in, thicker end uppermost, and to their full depth, and in boxes of light soil. Placed in frames, or under glass of some kind, both top and root growth will commence in a few days, and if planted out on good ground by the middle of April, or before leaves have actually developed, an excellent start will have been made. Root cuttings dibbled out soon after being prepared are liable to be preyed upon by slugs, and in any case the plants are not so forward and strong as those resulting from cuttings already growing when put out.

PLANT HOUSES.

Coleuses.—Young plants rooted in pots or pans must be potted singly, those rooted in small pots should be placed into 3-inch. If bushes are required pinch the plants as soon as they commence growing. For many forms of decoration plants with single stems and large foliage are very useful. Where bushes are needed early four or five cuttings may be inserted in each pot, and be allowed to grow on without pinching, and when a sufficient stock has been obtained old plants may be thrown out; they seldom grow freely, and are surpassed by young vigorous plants.

Balsams.—Directly the seed leaves have been developed pot the plants singly. Pot them down to the seed leaves, and when they have started again into growth place them on a shelf where the temperature ranges from 55° to 60° at night. If grown too warm they soon become tall and weakly, failing to branch freely.

Heliotropes.—Plants that flowered during the autumn and have been well cared for since will come into flower quickly if placed in an intermediate temperature. Young bushy plants that have been kept in 3-inch pots may be placed into 5-inch pots; in a temperature of 55° they will commence active growth, and prove useful for decoration.

Zonal Pelargoniums.—The best of those that flowered during the winter are showing buds freely; these will come into bloom in a few weeks if a temperature of 55° can be given them. Young stock should not be introduced into heat before their flower spikes are visible, for they are liable to start into soft growth and then fail to flower. Plants that have been cut back and are commencing growth may have the whole of the old soil shaken from their roots. These may be reduced, and the plants replaced into the same or smaller pots. Water carefully until they have commenced rooting and growing freely. Cuttings may be inserted in quantity for autumn and winter flowering. If inserted in small pots and kept growing they will be useful by the time it is necessary to turn them outside.

Mignonette.—For pyramids and standards to flower in the autumn seed should be sown of Parson's White or Miles' Hybrid Spiral in the centre of small pots. As soon as the seedlings are up select the strongest for standards; three or four may be left in the pots of those that are required for pyramids. Plants that have been in a cool house during the winter may be finally thinned if they are too crowded. It is a good plan to carefully bend over the surface of the pot those that are left. If this is done and the points removed they will break strongly from nearly every joint, and in a short time bushy plants a few inches high with large spikes of bloom will be the result. No attempt must be made to force these plants, they enjoy a cool airy place and a moisture-holding base. Water carefully, do not allow the soil to become dry, or the foliage will turn yellow.

Libonias.—If cuttings are not rooted they should be inserted at once. Those that are rooted should be placed singly into small pots and grown on for a time in heat. When a few inches high the point of the plants should be removed to induce them to branch. If large plants are required two or three plants may be grown together. For this purpose we invariably cut back a few plants and grow them well. For 5-inch pots single plants rooted at the present time are the best.

THE BEE-KEEPER.

WINTERING BEES.

BEE-KEEPERS who have examined their stocks will now be able to form an opinion as to whether the past winter has been disastrous to their bees. Judging from facts that have come under my notice I am inclined to think the losses will be more serious than usual, as already complaints have been received from various parts of the country. It cannot be owing to the severity of the weather, as no extremely low temperatures have been registered. On the contrary it has been excessively wet, and, as is now well known, dampness affects bees much more than a dry sharp frost.

There are, I think, three chief causes, which are queenlessness, shortness of stores, and excessive moisture in the hives. The former subject has been treated in recent notes, but the two latter would doubtless cause old and decrepit queens to succumb earlier than they would otherwise have done.

Shortness of stores is very common this season, and the cause is not far to seek, as during the late days of spring and early days of summer last year the weather was fine and dry throughout the country; but in the Midland and Northern counties very little surplus was stored. Afterwards a spell of dull showery weather set in, which continued, more or less, until the honey flow was over. By that time the greater part of the stores surrounding the brood nest had been consumed, whereas in ordinary seasons the end combs would have been full of sealed-up stores; the top part of many of the other frames, too, would have been in the same condition.

Although the weather improved for some weeks it was then too late, except in the Heather districts, for the bees to store a surplus. Thus many bee-keepers were deceived in the amount of stores the bees had, and as the autumn was excessively wet bees did not take the food readily that was placed within their reach, so that many colonies of bees went into their winter quarters short of stores, and unless candy has been given to them many stocks are on the verge of starvation. Several that I have examined during the past week are in this unsatisfactory condition.

DAMPNESS IN HIVES.

This is the cause of many colonies of bees being unhealthy, and steps should at once be taken to remedy any defects in the hive. It is surprising how rapidly a stock of bees will deteriorate if from any cause an excessive amount of moisture is allowed to remain in the hive. I have had experience of this on several occasions, and dread it more than anything else in the apiary. In this district foul brood is unknown, which is fortunate for bee-keepers; but next to that disease more stocks are lost from dampness in hives than from any other cause.

This fact should not be lost sight of by all who are interested in the pursuit of bee-keeping. If well-made hives are obtained they are liable to crack and let in the moisture after they have been exposed to the sun in summer and the frost and rain in winter for a year or two. It is therefore advisable to paint them every autumn, which will preserve them in good condition for many years.

If this operation is left until late in the autumn, when there are not many bees on the wing, the hives may be painted in the open air without removing the bees from the hive. This is an advantage, and takes up much less time than when the bees have to be placed in another hive. With loose floor boards and ordinary sized hives it is a very easy matter to replace a wet board with a dry one, as in the most carefully managed apiary too much moisture will occasionally be found in some of the hives.

Roofs may be blown off, and in connection with a mishap of this description I lately observed the benefit derived from the use of ticking for placing next to the frames, in comparison with calico for quilts. The former had been drenched with rain, but owing to the stiffness of the material, which was well fastened down to the frames by the bees with propolis, no moisture had penetrated to the interior of the hive. The other hive, which had the same amount of covering on the top of the quilt, which was calico, was saturated with moisture, and the bees had to be at once removed into a dry hive. Ordinary ticking is the best material for quilts, as the above illustrates.

REDUCING ENTRANCES.

If not already done this should be carried out without delay, as warmer weather may soon be expected, and as outdoor supplies will be scarce for some time to come, robber bees from strong colonies will be on the alert to gain an entrance to the stores of their weaker neighbours.

The best way to prevent this is to reduce the entrance to the

hive. In ordinary cases an inch will be ample at this season, more space being given to them as they increase in strength and supplies are coming in freely.

Should a weak colony be attacked it is advisable to reduce the entrance, so that only one bee can pass at a time. This will enable the rightful owners to defend their stores against the intruders. It is also an advantage to sprinkle a little carbolic acid on the alighting board, so that only a narrow passage is left clear for the bees to pass to their hive. This will usually have the desired effect; but in very bad cases where robbers have gained an entrance before being observed it is advisable to remove the hive from its stand, taking it several yards away. This should be done at night after the bees have all returned to their hives. An empty hive must be placed on the stand, the robbers will then soon find out their mistake, and will settle down to work.—AN ENGLISH BEE-KEEPER.

DOUBLING HIVES.

"AN ENGLISH BEE-KEEPER" (page 169) says "G. H." does not quite grasp the idea, and imagines more hives will be necessary. I may assure "An E. B.-K." my vision is clear on the matter of doubling hives, it being well understood here, but still think it takes more hives. "An E. B.-K." says (on page 20, January 7th), "Another hive the same size is then placed on the top and filled with empty comb, and the frames with adhering bees previously removed from the brood nest. If not of sufficient strength some frames of brood and the adhering bees may be taken from other stocks which are headed by old queens." Now from the above I still think more hives are needed, and the manipulation of several hives to make a strong one.

With our large hives we have found this unnecessary, and my contention is, Why go in for hives where a queen has not room for her ovipositing powers at the time most needed? for with ten standard frames the queen has no such room. It speaks well for large hives, at the present time (March 3rd) nearly covering nine frames. At the meeting of our Association (March 3rd) one of our members stated that day he had examined one of his hives, which has twelve frames, 18 inches by 9 deep; the bees covered nine frames, and he observed several drones. On February 20th strong hives were fanning at the entrance at nine o'clock in the evening. I find that large hives need less attention as to feeding. If stores are short in the month of August, and a supply is given to last until April, very little trouble is given to the bee-keeper, and candy feeding is found unnecessary with large well-provisioned hives.—GEORGE HOWDENSHERE.

TO CORRESPONDENTS

All correspondence relating to editorial matters should be directed to "THE EDITOR." Letters addressed to members of the staff after remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return rejected communications.

Address (G. N.).—The Secretary of the United Horticultural Benefit and Provident Association is Mr. Collins, 9, Martindale Road, Balham, London, from whom all particulars may be had.

Culture of Lapagerias (Journeyman).—The article on page 228 will doubtless be of more assistance to you than could a brief reply in this column. Lapagerias are, as you say, of very great beauty when well grown, which unfortunately is not always the case.

Peach Buds and Flowers Falling (G. P.).—You say nothing about the age of the trees. We suspect the root action is defective, or the soil lacking in necessary food ingredients. The wood is weak, and was not matured last year. Possibly the trees were attacked with red spider. Their condition must be improved for the retention of buds and the production of fine fruit.

Weeds on Lawns (H.).—We have seen lawns from which Daisies have been entirely banished by the proper and judicious use of "lawn sand," which is sold for that purpose. We have not seen deep rooting weeds such as plantains similarly eradicated. They are best drawn out with implements made for that purpose, but can be destroyed by sulphuric acid, which requires, however, to be used with particular care.

Men Employed in Gardens (W. E.).—The precise number of persons employed in the gardens you name is, we are authoritatively informed, twenty-six.

Chrysanthemums (T. T.).—No person in the world could give the required information without much better samples before him than those you have sent. If you wait until the leaves are more developed, then send samples characteristic of the varieties in a small box, with a little damp moss or green grass as packing, so that the leaves reach us somewhat in the same condition that they leave you, we will, as far as is possible, comply with your wishes, which, however, must be repeated, as your present letter cannot be preserved. Leaves simply enclosed in envelopes have the moisture extracted from them by the absorption of the paper, and the post office punches complete the finishing process of destruction.

Yew Wood (G. Hart).—The wood of the Yew is remarkable for its toughness and elasticity, and is celebrated for the purposes to which it was anciently applied in making that most formidable weapon of our ancestors, the longbow. The wood is at present valued by cabinet makers and inlayers on account of its beautiful red veins, and it is also a good material for flood gates, cogs for wheels of mills, and other works where strength and durability are required. We have no idea of its commercial value at present, so little being placed in the market of English growth, and other woods being so cheap; but there is a demand for heavy woods, and probably this may apply to Yew. Could you not consult a timber merchant or make inquiries of cabinet makers?

Proportion of Seeds to Length of Row (Tyro).—We do not think the estimate is very far wrong. We do not approve of so-called cheap and doubtful seeds and sowing thickly, but prefer thoroughly good seeds and sowing thinly. A quart of Broad Beans will sow a row of about 150 feet; Early Peas, 140 feet; Late Peas, 160 feet; Scarlet Runners, 150 feet; Dwarf Kidney Beans, 280 feet. An ounce of Onion seed will sow a drill of 150 feet; Carrot, 180 feet; Parsnip, 200 feet; Beet, 60 feet; Parsley, 180 feet. In sowing small seeds broadcast half ounce of Lettuce or seeds of the Cabbage tribe suffices for 8 square yards, and 1 oz. of Radish seed will sow 5 square yards. As to Potatoes the length of row a peck will plant depends on the size of the tubers. The early varieties as usually sold will extend over about 150 feet length of row.

Depth and Distance for Sowing and Growing (Idem).—Broad Beans—Rows, 2 feet; seeds, 4 inches apart and 3 inches deep. Sow very early (March). Scarlet Runners—Rows, 8 feet; seeds, 6 inches apart and 3 inches deep (May). Dwarf Kidney Beans—Rows, 2 feet; seeds, 5 inches apart, 3 inches deep (May). Peas—Rows, distance equal to height of plants; seeds, 2 inches apart in flat drills, 3 inches deep (February to June). Onions—Drills, 10 to 12 inches apart and nearly an inch deep; thin the plants to 4 inches asunder. Sow in March or early April, and early in August. Carrots—Early Horn, sow in March or early April, cover the seed, and thin the plants the same as Onions. Main crop, end of April, thinning early to 5 or 6 inches apart, in rows quite a foot asunder. Parsnips—Drills, 14 inches apart and 1½ inch deep. Sow early (March), thin to 6 or 8 inches asunder. Beet—Drills, 15 inches apart and 2 inches deep; Turnip-rooted for summer use sow in April, long-rooted early in May. Thin early to 8 inches asunder. Turnips—Drills, 15 to 18 inches apart and half an inch deep. Sow thinly April to July (ready in about eight weeks), later for storing. Thin early to 9 inches asunder. Small seeds of Cabbage, Lettuce, and Winter Greens are best sown very thinly in drills 6 inches apart and ½ inch deep. The first smooth seed leaves should not touch each other. When 2 or 3 inches high dib the plants 5 or 6 inches apart to get sturdy for final transplanting in showery weather with small forks. Many plants and crops are spoiled by sowing seeds too thickly, leaving plants unthinned too long, and transplanting too late. Good sets of early Potatoes may be planted about a foot apart in rows twice that distance deep when the ground is dry in March or early April. Cover the sets 4 inches deep in March, 3 inches in April. Hoe between all rows once a week to prevent weeds, and draw out those in the rows when the weeds are half an inch high.

Planting Shrubs (S. E. H., France).—Shrubs for winter flowering in the position named are *Azara microphylla*, *Elæagnus glabra*, *Viburnum tinus* (Laurustinus),* *V. t. Roebeli*,* *Photinia japonica*, *Skimmia japonica*,* *Chimonanthus fragrans*,* *Cydonia japonica*, *Daphne Mezereum**, and its varieties *atrorubrum** and *flore alba**, with *Jasminum nudiflorum* (climber). *Rhododendron catawbiense*, in several shades of colour, often flowers in February, but usually in March. Those marked with an asterisk are the most reliable. Both winter and spring flowering shrubs may be safely transplanted during the next three weeks, or even later if the plants are obtained in pots. Should it not be convenient to carry out the work now it may be delayed till October or November. To insure success in planting a dry bank in a shady position, the soil must be thoroughly prepared. If the bank is closely interlaced with tree roots the stronger ones must be cut away with an axe. The ground should then be dug with a spade to the depth of a foot if possible, placing well decayed manure in the bottom of the trench as the work proceeds. If a few inches of fresh soil can then be placed over the surface the plants will make quicker progress, but this is not absolutely necessary. At a distance of 7 feet apart plant *Cotoneaster microphylla*, and train the shoots to strong, upright stakes; then over the whole remaining space *Vinca major* and *V. minor*, keeping the smaller variety near the edges of the bank. If the plants are set 10 inches apart they will soon grow into a compact mass, and give but little subsequent trouble. The best time of the year to carry out the work is early November. If done during the present month a little attention in the way of watering will be necessary during the first summer.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, at being often difficult to separate them when the paper is damp. (J. G.).—Only one specimen was in a proper state for identification, all should have been in flower or in fruit. Possibly they are—1, a *Pittosporum*; 2, a *Crataegus*; 3, a *Berberis*; 4, a *Ceanothus*; 5, a *Clematis*; 6, is *Cornus mas*.

"BY THE WAY."

WITH a prospect of grass keeping becoming more abundant as spring advances, and spring, as we write, seems not only at our door, but over the threshold, it appears to be but natural that we should ask ourselves with what are we stocking our pastures, and what are the prospect of such stock for the future. We have before us the American live stock statistics published on January 1st, 1897, and we think they afford very instructive reading for all interested in the breeding and rearing of cattle and sheep in this country.

It would serve no useful purpose to give the statistics in full

but we may briefly state that whereas cattle in the United States reached their maximum numbers—viz., 54,068,000 in 1892, and sheep their maximum of 47,274,000 in 1893, both have gradually fallen in numbers since then, so that now they amount to—Cattle, 46,450,000; sheep, 36,819,000. What has become of the 8,000,000 cattle which the States have lost during these five years? We have received into this country during that time from there in cattle (and fresh beef representing cattle) something like 4,000,000, but this accounts for only half the 8,000,000. It would appear, therefore, that at recent prices it does not pay the American farmer to rear stock for home consumption, and that he has given up trying to do so, or that the demand in the States has so increased during the last two or three years that the supply has been quite unable to keep pace with it. The latter solution seems the more reasonable, for prices have certainly risen during the last few months, a result which was inevitable under the circumstances.

Will a rise—that is, a reasonable rise—in price have any very appreciable effect on the supply? We hardly think so. Unlike pigs, cattle cannot be rapidly bred up to existing requirements, so we hold a firm opinion that a higher range of prices for beef will be attained, at any rate for the next two or three years, if not permanently. This being granted, it would appear that the rearing of calves should prove a remunerative investment to farmers whose holdings are suitable for the purpose. With a better demand for beef, we are sure to have an even better demand for meat-making machines, so let us stock for 1898 as well as 1897.

The reduction in the number of States sheep is not likely to affect us so materially, as mutton is a product with which the Yankees have never supplied us to any great extent. It, however, adds force to our contention that the British consumer will have to look elsewhere than the United States for his meat supply, unless he is prepared to pay such a price for it as will stimulate the American farmer to the production of meat, not in the present, as we may style it, ranche fashion, but more as we produce it in England.

No doubt many farmers will say that they already breed as much stock as they can carry. But do they make the most of the food produced on their farms? For instance, do they use much straw as bedding? By the use of peat moss litter almost the whole of the straw may be consumed as food; but in order to do this it must be cut up and mixed with roots, or made appetising by the addition of a little meal, treacle, or grains.

The question, "What can the farm be made to carry?" suggests another, "Do we make the best use of our seeds and grass?" When Clover seeds are dear farmers are apt to cut down the quantity usually sown. They cannot afford more at the price, so they run the risk, for the sake of perhaps 2s. or 3s. per acre, of having only half a plant, and therefore a pasture worth less to him by £1 or 30s. per acre than it would have been if he had been liberal with his seed. Considering the great value of the Clover crop it is amazing how careless farmers are not only about the quantity of seed but the quality they use.

Clovers are this season fairly reasonable in price at present, though there is some talk of a prospective rise, so that if bought at once whites can be had very good at 10s. per stone and red at 9s. Inferior seed can be bought much cheaper, but it would be dearer in the end. When we consider that we have the same labour bill and the same rent to pay whether our pastures are good or bad, it is obvious what a penny-wise, pound-foolish policy it is to be miserly as regards the seed bill.

Whilst on the subject of Clover seed we may take the opportunity to recommend a variety called "Giant White." We have found it much more productive than the ordinary white, and carries a much heavier head of stock. It is nearly as large as red Clover, from which it may be a sport. We have only tried it for one year's pasture so cannot say whether it is perennial or not.

Very considerably increased returns may be obtained from poor meadows and pastures by the judicious use of artificial manures. The number of cattle a farm will carry is only limited by the amount of cattle food the said farm can be made to produce, for heavy stocking does not affect the healthiness of cattle, as it is liable to do that of sheep. So that if the crops of grass can be increased 20 per cent. a proportionately larger number of beasts may be fed.

To those who wish to improve poor grass, and have not farm-

yard manure to put on we would suggest a little experiment. Top-dress a portion at once with 80 lbs. nitrate of soda and 200 lbs. superphosphate of lime per acre. Have the dressed part carefully marked out, and watch the effect.

WORK ON THE HOME FARM.

We have again to record a week of disappointment. The high winds which appeared likely soon to produce March dust in plenty, have been followed by drenching rains (one day we had a thunder storm), and where sowing has been done it has been with difficulty, and can hardly prove satisfactory. So far March has not fulfilled the hopes we had of it; the land seems almost as sodden as ever, and meanwhile time is passing. Every effort must be made to get sowing finished between now and April 10th.

The question when to sow Clover and similar seeds is an important one. We favour sowing early, immediately behind the corn drill, and harrow seeds and grain in at one operation. A plant of seeds under these conditions is almost a certainty. True, there is the danger of the Clover getting big amongst the corn, and making it more difficult to harvest, but it is a lesser evil than having no seeds.

Lambing proceeds slowly, but with fairly good success. The crop of lambs is in some cases large, and taking the district as a whole quite up to the average. Young seeds have grown in a wonderful manner, the Rye grass being several inches long, so there is plenty of food for the ewes when it is wanted. We put the pairs on seeds as soon as we can get them out, but keep the singles on grass, and give them a few Mangolds.

Turnips are nearly finished, and the sheep clippers are in demand. Clipped sheep are plentiful in the local markets—in fact, are now the bulk of the show. Fortunately for those who now have to sell, the markets are decidedly good, a falling off in the imports of dead sheep having given an impetus to the demand for home-bred mutton.

We are ridging for Potatoes one field which was manured during early winter; we shall have the planting done immediately. Another field is all ridged out, but is waiting for the manure, which will be taken straight out of the covered yards. If the Potatoes are then quickly planted and the ridges split with the plough there should be little or no loss of ammonia.

One piece of land we are planting with a new variety, which, being large in size, we shall have to cut. We shall cut them a couple of days before planting, and have no fear of loss from dry rot, which sometimes occurs if they are cut and planted immediately.

OUR LETTER BOX.

Churns (H. J.).—For so small a quantity of cream as 12 lbs. the simple wooden churn is best—the kind with the horizontal barrel. The opening for pouring in the cream should be as large as possible. It is also important that no part of the churn should be out of reach of the hand. It should also have a simple and sufficient lid, and the whole thing must be light, convenient, and durable. The Dairy Supply Co., Museum Street, London, is a very reliable firm.

Comfrey and Lupins for Fodder (S.).—The white Prickly Comfrey is planted and grown in the same way as Rhubarb. It is requisite that the soil be rich, deep, and moist for promoting quick succulent growth. If the growth is slow, as in poor, dry soil, the leaves are bitter, and animals will not eat them. Good single crowns are planted 3 feet asunder, at this period of the year, and the ground around them covered with manure. No leaves should be cut or gathered the first season. The common yellow Lupin is grown on the Continent as a fodder crop, chiefly in poor sandy soil. The seeds are drilled early in May, in rows 15 inches apart, at the rate of 2 bushels an acre. The crop is only to be recommended in this country where the land is too poor for Vetches, Lucerne, or Clover.

Barter's IN VICTA GRASS SEEDS

FOR

Garden Lawns, Tennis Lawns,
Croquet Grounds, Bowling Greens,
For Shaded Places.

Entirely Supersedes Turf, which is always full of vile weeds.

Old, worn out, and mossy pieces of Grass can be renovated at little expense if the following directions are attended to.

Lightly scratch the surface with a rake, to make a bed for the Seed, which sprinkle over the ground at the rate of 1 lb. (costs 1s. 3d.) to every 500 square feet, and the contents of a 3s. box of Carter's Lawn Manure (No. 1 prescription); cover the whole with a barrowful of good clean loamy soil. Brush it over the ground, then thoroughly well roll down. Choose a dry day for the work, and where the Grass is very thin do not stint the Seed. If there is no rain within a few days after sowing, and dry winds prevail, a good watering is desirable. Do not cut too closely at the first two mowings.

Estimates for Quantities on application.

Barter's New and Improved Flowers

CARTERS' HOLBORN PRIZE PRIMULA.

We commenced growing and saving our own seeds of this popular winter-flowering plant forty years ago, and have since carefully selected and improved our strain, that we unhesitatingly pronounce it the finest in cultivation; and as we try all others each season for comparison, our statement is authoritative. We were the originators of the Blue Primula, which resulted in some cross-breeding experiments we were making to this end; and were awarded a First-class Certificate by the Royal Horticultural Society, in 1882, for the first Blue Primula ever offered. Our collection also comprises the following beautiful colours:—Scarlet, Carmine, Magenta, Ruby, Vermilion, and White, all of which originated at our Nurseries, and are the most approved types at present attainable.

Each separate, in sealed packets. Price 2s. 6d., 3s. 6d., and 5s., post free.

All Colours, Mixed, in sealed packets. Price 2s. 6d., 3s. 6d., and 5s., post free.

CARTERS' BRILLIANT PRIZE CINERARIA.

Our House has long been famed for this beautiful flower, and our strain is unequalled for profusion of bloom, size of flower, and general habit. We grow all our own seeds, and test other strains each season. A magnificent group exhibited at the Royal Botanic Society's Show, in the spring of 1896, easily gained the First Prize.

In sealed packets, 2s. 6d., 3s. 6d., and 5s. each, post free.

CARTERS' VICTORIA PRIZE CALCEOLARIA.

Our fine strain is well known at all the leading Horticultural Exhibitions, where magnificent specimens have secured First Honours on nearly every occasion.

In sealed packets, 2s. 6d., 3s. 6d., and 5s. each, post free.

ILLUSTRATED CATALOGUE, Post Free.

Journal of Horticulture.

THURSDAY, MARCH 25, 1897.

AN OLD WALL.

"GREAT ruins make way for greater glories." This is the case with our old wall. Probably not upon the lines laid down by that gifted man Seneca, whose high philosophical teaching made apparently so little impression upon his pupil Nero. Apparently? Who can say how ran the imperial fiddler's thoughts when Rome was burning, and whether his tutor's moral had not applied the torch to the City of the Seven Hills? No one can look upon our wall without being carried to the past—to Elizabethan times at least, for does not report say that the Virgin Queen slept in the old mansion near at hand? It does; and we like to believe it; to believe, too, that great Elizabeth passed under the arch in the old wall with gallant Raleigh or courtly Leicester and all her gorgeous train. Unfortunately the huge Wistaria, now showing the tints of hundreds of tresses adorning the head of the arch, is not contemporaneous with that event.

Unquestionably our old wall is a relic of Tudor times, although we are unable to trace the quaint conceit which placed it between the garden proper and the mansion, belonging neither to the one nor the other, yet having some relation to both. Over the arch we have set the Fleur de Lys—the Flag Irises, and they have flourished amazingly. To do so we had to make some cavities—or rather, to assist the hand of Time by dislodging a few more of the rich red bricks. Our wall is of bricks—for there were brickmakers in those days, and builders too, and whatever the labourers were paid they were worthy of their hire, for they went down to the solid on which to set their foundations, and our old wall still stands as aplomb as the day it was built.

"Wants repairing, it do," says our handy man, "and all they weeds and rubbish cleared off the top; a letting in the wet, they be," and with this parting shot he slinks away, for there is danger in our eye, insanity he possibly thinks. Perhaps we are a little more fearful of our head gardener, who has long cast a covetous eye over the length and breadth of its south-west aspect. Could we be prevailed upon to give this up to him we might, I know, have undisturbed possession of the other side on which the "stiff nor-easter"

blows; but closing our ears to all insinuating reminders of juicy "Georges" and luscious Louise Bonnes we look lovingly upon our old wall, fill our dishes elsewhere, and let trimness and tidiness go to the other part of the grounds. It is, of course, very wrong—that is, so far as the right side of the wall is concerned, and we duly and daily feel our perverseness, plead guilty, but can't give way, so have to stand a fire of criticism, from the rough and ready shots of our handy man to the polished shafts from our accomplished *chef*, who, saying less, means more, for the dignified wave of his hand to our wall when hurrying past his friends to the supreme examples of law and order appear to "Convey a libel in a frown, and wink a (our) reputation down."

Just now we are inflated with pride as the bursting buds of glorious patches of Daffodils at its foot tell us that spring has come. Patches that one may walk through and about without leaving tell-tale footmarks behind, for be it known to our shame that we neither delve nor dig save to introduce some especial favourite to the general confusion. Confusion? No! There is method in our madness, as you may see by those grand masses of *N. princeps* now waving in the wind. Horsefield's, Emperors, and other mighty trumpets play no mixed medley, each company keeping their own ground. All these things, and more also, are under the protection of ourselves and the old wall, but there comes wafted down from the crummiest part of its crumbling summit a delicious perfume recalling the wandering senses to our chief object. Wallflowers pure and simple, not fatted up with manure for the beds, but bravely holding their own; humble members of their kith and kin, just old brown and golden yellow.

Away at the far end where the trees will shade from the noon-day heat of summer suns, into every available crevice, and they are many, more shame to us again, *Erinus alpinus* has crept; later on the setting sun which finds its way there will light up the myriads of tiny blossoms into a warm glowing mass of beauty. Roses, which (alas!) will never deck an exhibition board, we shall fairly revel in, in tangled masses of yellow *Banksians* and white *multifloras*. At that time it may be a relief to retire into the cool shade of the other side, where the simple *Rue Fern* and the *Ceterach* are at home. At the foot yet rest many crowns from which the *Lady Fern* will soon unroll its graceful fronds. Already, here, patches of *Venus's Navelwort*, *Omphalodes verna*, have opened their eyes of heaven's blue. It is very beautiful, just a little too leafy, but its luxuriance testifies to the presence of the limestone which it loves.

Yet one would fain return and linger at the south-west side of our wall where the sunbeams are trapped and note how, even so early in the season, the potent days are warming back to life and beauty climbers, and creepers, things above and things below. Warmth and Life. Our feathered friends are already busy; a pair of tits, blue-headed busybodies, disappear through a marvellously small portal into a snug retreat, whilst there are sundry nests of the blackbird and thrush, last year's homes, in excellent repair; but the former tenants are about to build upon other eligible sites, comprising an old *Magnolia*, sundry varieties of *Honeysuckle*, *Pyrus japonica*, with other bushy or tangly things. We have a weakness for *Ampelopsis Veitchi*, so much so that a little restriction is necessary or our old wall would soon be entirely hidden; but there are peeps of the warm red crumbling brick that one would fain keep.

Years ago a crimson Snapdragon settled itself in a breach; it has multiplied and replenished on that particular spot in the happiest manner. We have, of course, introduced various things with partial success on both sides of our wall, of which we may have something to tell later on, provided that contingencies hinted at are averted. Our old wall, venerable, picturesque, comforting on the sunny side now in its Riviera-like clime; grateful on the other when dog days deserve their name, and taken all together and at all seasons the favourite spot in a favoured garden of—THE SQUIRE.

HARDY BULB CULTURE IN ENGLAND.

[By F. W. BURBIDGE, M.A. Read before the Birmingham Gardeners' Mutual Improvement Association, March 15th, 1897.]

WE are told by politicians nowadays that thrift and home industries are essential, and whilst some advocate milk or meat, or poultry and eggs, or jam making, or the "busy bee" industry, I will advocate bulb culture. We have here in Birmingham our friends Mr. W. Sydenham and Mr. Pope, and others interested in bulbs, but I should like to see every small farmer, every cottager and allotment holder, and even the railway porters growing at least a few bulbs for sale.

In Holland and elsewhere it is the small growers who supply the wholesale growers and merchants, and I should like to see the day when Mr. Sydenham and others of our great bulb merchants are not obliged to go over to Holland with their big cheque books once or twice a year.* Bulb growing is safer and more pleasant than gold or diamond mining, even though, perhaps, not quite so profitable as "bicycle booms" and breweries, or some cornered shares on 'Change. We all want more faith. If the English gardener has one greater fault than another to-day, it is that he does not believe in himself, and in the soil and climate of his native land.

So far as general energy and garden skill are concerned no gardener on earth can beat the English gardener, and what seems to me of paramount importance just at this juncture is that the English gardener should have faith in his own ability, and more especially faith in his own climate and in his own soil. He should also be more eager and careful to learn thoroughly the technics of special cultures, whether of fruit trees, vegetables, flowers, or bulbs. We want the intimate and special practical training that the Dutch bulb growers turn to such a national advantage. This is no new Gospel, for the text itself has been preached from the days of Dr. Bulleyne of Ely, in 1570, to those of Miller, of Chelsea, in 1731. Miller, in his great "Gardeners' Dictionary" under "Tulip," especially recommends English growers to compete with those of France and Flanders or Holland in the rearing of these and other hardy bulbous flowers from seed. My present object is twofold, and I wish to show that bulb culture may be a profitable form of land culture, and that the rearing of new varieties of bulbous flowers from home-grown seeds may be a most intellectual and interesting pursuit whether it be profitable or otherwise.

It has been well said by many good authorities that English farming in the future will resolve itself into "gardening in the fields"—that is to say, that at a time when corn and meat and wool can be imported as cheaply or more so than we can grow them for ourselves, then English soil wherever suitable may be best utilised in growing fresh flowers, fruits, vegetables, milk, and other commodities not so easily and cheaply imported to our shores.

Bulb culture in Holland, and South France and Italy, in the Channel Islands and in Cornwall, and in the Isles of Scilly, has proved to be the most profitable of all cultures on suitable sites and soils. The soil, and especially the mild and early climate in Scilly, is an advantage; but the methods of culture there are generally of a very simple and ordinary kind. The same is true in some other parts of England, as in Lincolnshire, in many market gardens and nurseries near London, and in the Isle of Wight.

There are already hundreds of acres in Great Britain and Ireland under bulb culture, but there is room and demand for more. We may never export many home-grown bulbs, but so far as *Narcissi*, *Crocus* and *Tulips* are concerned, we might easily grow our own supply. There are many growers here and there who are making a good living, even though not a fortune, by careful bulb culture. As you go about through the country, and especially near most large towns, you see rows and strips of bulbs almost everywhere. Now that is a good sign, and though the cultivators do not stand shouting out to the passer-by as to bulbs being a paying crop, yet it is true all the same. A man who is doing a good business is, as a rule, a sober and industrious man, content to eat a meaty bone in peace and quietness.

Let us ask what a bulb really is?

A bulb is simply a large bud with close-packed fleshy leaves, or leaf bases, in which are stored an accumulation of starch, sugar, and other concentrated plant food. As hibernating animals store up fatty matter before going to sleep for the winter, so do bulbs store up surplus food and hide themselves underground so as to go through cold or drought unharmed. This habit renders bulbs so handy and convenient for distribution at certain seasons of the year. Bulbous plants are due to sudden changes of temperature or of drought and moisture, such as occur in the great natural bulb fields of the world. These are in Southern and Eastern Europe, in

* At the very lowest calculation, England pays £100,000 to the Dutch bulb growers every year.

Western Asia, in North Africa, and at the Cape of Good Hope. Broadly speaking the climatic conditions of these places are very cold or dry in winter, rainy and warm in spring, followed by a blazing hot and dry summer and autumn. Hardy bulbs may suffer during a dry and hot spring, but they cannot well have too much moisture at the roots when in growth, and they enjoy warmth and drought when at rest.

In order to grow bulbs to the best advantage for trade purposes they must all be lifted and replanted every year. Here again we must follow out the good gardener's axiom of doing the right thing in the right way or manner, and at the right time. The bulbs must be dug or lifted as soon as the leaves turn yellow and fade, in June or July at latest. Above all dig too early rather than too late; dig before the leaves fade entirely rather than after new roots grow from the base of the bulb. On most deep, rich, sandy soils bulbs, such as Narcissi and Tulips, &c., ripen off in June or July, and should then be dug, assorted, and cleaned ready for sale or replanting. A light, dry, and airy bulb shed, fitted with lath or open-work shelves is convenient for storage; but much may be done with strong lath boxes that will stack one above another in field or garden, and which can be covered over temporarily when it rains.

The first thing is to select the land most suitable to bulbs of various kinds. Even in Holland and other places where bulbs are and have long been a special culture, success can only be assured on certain plots of suitable soil. Again, the land that grows the best Hyacinths is not so suitable for Narcissi, or for Tulips, even in Holland. I think the Dutch pre-eminence in bulb culture is more due to their methodical thrift and skilful industry—an hereditary gift to them—rather than to the super-excellence of their soils or their climate.

Where suitable land can be had, and it is tolerably level, a plough followed by a three-pronged cultivator to loosen the subsoil, may be used with economy, but in rocky plots on a steep gradient, and elsewhere on small areas, the spade is the best implement to use. Again, land, however good, won't grow bulbs year after year for ever, without manure or some recuperative rotation of cropping. On large bulb farms the ground is well tilled and enriched for vegetable crops, or Clover and Rye Grass, and then well worked after these for bulbs to follow. In any case, never use crude or farmyard manures direct for bulbs. Bone superphosphate, and wood ashes or kainit, may be worked into the soil with advantage a week or so before the bulbs are planted. I have also seen nitrate of soda and wood ashes and soil used with advantage in February as a top-dressing.

There are in England to-day thousands of acres of derelict land suited for bulb culture. All around our sea coasts, especially, there are sheltered sunny nooks and valleys that are unvexed by wind and unscathed by biting frosts, even during our usual winter season. These places require selection and utilisation; in a word, we must discover our own land. You don't want the expensive horse power, the deep tilth, and the heavy manurings necessary for Swedes or Mangolds in order to grow bulbs successfully, but you must have a loam sufficiently sandy to be workable even during a rainy season.

(To be continued.)

ONCIDIUM SPLENDIDUM.

I AM quite persuaded that amongst the many Orchids in bloom with us at the present time there is none claiming greater attention than the beautiful Guatemalan species, *Oncidium splendidum*, and considering the perfect ease with which it may be grown it is not only worthy of inclusion among large collections, but is quite as essential in those of the small amateur growers. To grow it successfully place the plants in shallow baskets or pans, using a compost of peat and sphagnum moss. After potting the pans should be suspended from the roof of a house having a temperature of from 55° to 65° during the summer, shading from strong sunshine and giving free supplies of water as growth advances, diminishing during the autumn months. I have seen many fine plants fail to produce their flower spikes through a check of water during the summer time. The flowers, which are produced on strong upright spikes, have the sepals and petals banded with bright brown; but perhaps the predominating feature is the broad lip, which is of a lovely shade of bright yellow.—R. P.

TRICHOGLOTTIS COCHLEARIS.

THIS pretty little Orchid does not seem to be very generally known, judging by its rare appearance, even in large collections. The plant is dwarf in habit, and has thick slightly channelled leaves arranged in Vanda-like manner on opposite sides of the stem. The flowers are borne three or four together in small racemes springing from the axils of the upper leaves, and are remarkably pretty. The sepals are lanceolate; the petals are broader and rounder at the upper part, both being pure white barred with bright purple—a charming contrast. The lip is curiously hollowed or scoop-like, terminating beneath in a short

FIG. 54.—TRICHOGLOTTIS COCHLEARIS.

conical spur, and the form being somewhat suggestive of a shell has given rise to the specific name adopted. *Trichoglottis cochlearis* is a native of Sumatra, whence it was introduced by Messrs. J. Veitch & Sons a few years ago.

VARIATIONS OF SEEDLINGS FROM FRUIT.

No doubt raising seedling fruit has for many years been a matter of great interest to those who have entered all forms of fruit culture, and pomologists have attempted, with more or less success, to secure improved varieties of fruit with rather less than more success. One name, that of Andrew Knight, has achieved a lasting reputation in England, and the name of Van Mons in Belgium is equally well known as the raiser of numerous Pears, the greater part of which have not retained the position he claimed for them. The Pear known by his name, the "Van Mons," (Leon le Clerc) not being a seedling, but named by the raiser (Leon le Clerc) as a compliment, the compliment being returned by a Pear named Leon le Clerc (Van Mons), a very inferior fruit, and fit only for the kitchen.

The number of Pears described by André Leroy and Dr. Hogg testify to the persistent attempts of seedling fruit raisers to obtain Pears of superior quality. It is natural to suppose that for this purpose the fruit selected for sowing would be of the best quality, and yet how disappointing are the results. New fruits appear and disappear in regular order, for whether the failure is caused by soil or climate, it is seldom indeed that varieties carefully cherished by the raiser fulfil the description given of their qualities.

The eccentric differences observable in Pears alone are exasperating. Crossing with sorts possessing superior qualities does not appear to give any special results; there is always the element of chance, and the careful experimenter is beaten by a

chance-grown seedling. The Duchesse d'Angoulême, a most popular Pear in France, the climate being better suited for its development than England, was found in a farm garden near Angers; the Baurré de Rance also being derived from a small village garden in Flanders. There is a strange adherence to the prototype in some Pears, the Jargonelle for instance. This Pear is a standard of excellence of some. Under the name of Epargne it is said by Andre Leroy to have been a popular Pear in France in the year 1580. During this long period there does not appear to have been an exact reproduction. Synonyms there are in plenty, Leroy gives twenty-two, but there is not a hint that they represent seedlings.

One of the oldest known Pears in England, the Autumn Bergamot, said to have been introduced by the Romans, has seedlings in plenty, and a long list of synonyms, but apparently no exact reproduction. The seedlings are earlier and later, larger and smaller, but none are exactly like the prototype. Another popular Pear, the Marie Louise, persists in keeping the place it has gained; numerous synonyms, but no seedlings which exactly reproduce the original. This Pear, from its excellent quality, must have been a source of many experiments. Of other typical Pears which have not been reproduced the following will be familiar examples:—Williams' Bon Chrétien, Louise Bonne of Jersey, Glou Morceau, Doyenné du Comice, Passe Colmar, and Easter Beurré, though they have been in existence long enough to have produced many seedlings. I have raised seedlings from these varieties, and have not gained a single fruit like the parent, and in fact all have been more or less worthless.

As with Pears so with Apples. The Ribston Pippin has not to my knowledge been reproduced; it is said to have been raised from a chance seedling. The Wyken Pippin, a very old and esteemed variety, has not reproduced, or the King of the Pippins, and Golden Pippin. Old Nonpareil, of which the seedlings are nearer the prototype than most of the old varieties, is not exactly reproduced.

The Peach is perhaps the fruit which approaches more nearly reproduction than most, but does not differ much from the apparent rule of diversity. The Grosse Mignonne, Bellegarde, and Madeleine have numerous seedlings which approach the originals in quality, but differ in the flowers and glands. The catalogue of the Royal Horticultural Society enumerates forty synonyms of the Grosse Mignonne. These do not appear to be seedlings, but the names seem to have been given by those who have grown the sorts, but lost the original names.

Nectarines are subject to the same law. The Elrue and Violette Hâtive seem to have kept to their types. The Plum has also an apparent fixity of tenure. The Green Gage, which was introduced into Europe many centuries since, seems to have adhered to its prototype, although it is said to be raised from seed, with the result of perfect reproduction. The number of synonyms points rather to the fact that seedlings vary, as do the seedlings of other classes. The Early Prolific, of which I have raised many seedlings, does not reproduce itself, and the fruits differ essentially from the parent.

Cherries are also subject to the same law. The number of synonyms accorded to the May Duke, Bigarreau, and the Reine Hortense seem to show that exact reproduction has failed. The subject is interesting, and is capable of much extension. In our uncertain climate the aid of glass is almost absolutely necessary, and the experiment, if a man wish to see the results, should be begun at an early age.—T. FRANCIS RIVERS. (*Read at the Horticultural Club.*)

HARDY FLOWER NOTES.

RUDE and boisterous as are many of the days of Amazonian March, as the Poet Laureate aptly calls the month, they bring us new revelations of the loveliness of early flowers. They come with timorous feet, shyly peeping out upon us from many a corner. So lovely are they, so sweet and delicate, that one can only wonder at the marvellous process by which these graces of form and charms of colour are evolved from the dark earth. From that dusky mother these nymph-like flowers, pure as the driven snow or bright as the hues of the rainbow, have sprung.

See that Daffodil, with its golden trumpet with serrated mouth; that pale one, which looks as if it had borrowed from the moon its passionless light. Look at that Iris of blue velvet bedecked with gold; that Glory of the Snow, which from the hills near Smyrna once gave amid the snow the colouring of the North American *Nemophila insignis*. See these Crocuses, with their cups spread open to the sun, and think of their beauty. Are they not marvels indeed? So might we say again and again as we see that mound of *Saxifraga apiculata* spangled with its primrose flowers; that little one of *Saxifraga Boydi* with deeper coloured blooms; the Scillas, the early Heaths, the Primroses, the Snowflakes, and other flowers,

which, from the rockwork's slopes or the border's level surface challenge our notice and compel our admiration. We may too with safety say that with March has come the Daffodil.

In February, it is true, a few adventurous ones dared to thrust their trumpets through their spathes and open their flowers to win our reluctant praise. No less true is it that here April is the month in which these queens of spring receive our highest homage; yet in March, the traditional month of the flowers, there are Daffodils enough in bloom to give them the pride of place with their perfect flowers. Even now, early in the month, several are in beauty, and no one can sit down to write of hardy flowers of the season without referring to two or three.

As usual, the dainty little *Narcissus minimus* came first. A little later than in some other years has it been; but before the middle of February had come it brightened its allotted portion of a sunny rockery. A few of the blooms would have opened before the 5th of the month, but these were found by the slugs to be delicious food ere the marauders were discovered in their haunt. The next to give us pleasure were a couple of flowers of the *Sargossa Daffodil*, which, though not large, were very pleasing with their clear self-yellow blooms. There was next a race between some plants of pallidus *præcox*, minor, and one scoticus, which is perched on the top of a sunny rockery, and had been driven early to rest last year. It is hard to say which of the three was first; but all were welcome when they opened when March came in.

Now, as I write in the second week in March, the quaint *Cyclamineus major* has turned back its perianth segments, and looks quaintly pretty in its pocket at the foot of a rockery where, although in full sun, it gets its share of the water applied to the alpines above in dry weather. It looks like some freak of Nature, and had we lived in legendary times we might have imagined that some magician had sought to make a *Narcissus* into a yellow *Cyclamen*, but had been only partially successful in the attempt. One feels some pleasure in retaining this unique little flower for a few years after several failures to establish it, and it would be a victory indeed to be successful in establishing *N. triandrus*, which has hitherto baffled us here.

The bright looking *Hyacinthus azureus*, mentioned recently by the writer under the erroneous name of *Muscari azureum*, by which it is sometimes known, is yet in flower, and has done better than in any former year. Its reputation as a hardy bulb is a little "shady," if one may use such a term, and *amphibolis* and *robustus* have been recommended as being hardier. The writer has no experience of either of these, but has found the typical *H. azureus* hardy under the same conditions as *Narcissus cyclamineus*, with two exceptions. These are that it is much the better of a small piece of glass so elevated above the plants as to throw the rain off them, and a zinc ring to keep off slugs, which take pleasure in destroying the flower stems. The rain lodges in the cup formed by the leaves at the base, and if this remain too long or become frozen the flower stalk rots off. It is some trouble, no doubt, to take these precautions, but the capacity for taking pains is a characteristic which must be developed if we are to succeed with many plants in this climate.

But to return to the flower itself. The sky blue *Hyacinth* is like a Grape *Hyacinth* in general appearance. The small flowers are densely packed together in a conical raceme. The name sky blue fairly well indicates the general colouring of the flowers. The flower scape grows here to about 4 inches in height, rather less than the *lorate*, glaucous, and nearly erect leaves. The species is a native of Asia Minor, and the authority by whom it was described is Mr. J. G. Baker. A rather light and peaty soil appears to suit this pretty and distinct-looking little flower, which has a charming effect associated with *Snowdrops* and some of the yellow *Crocuses* or early yellow *Primroses*.

A pleasant surprise in the way of cut flowers came by a recent morning's post. The first box came from Mr. W. E. Gumbleton of Belgrove, Queenstown, than whom there is no one more eager to put new flowers to the test of growth, and to whom I have frequently been indebted in many similar ways. The box contained two shades of flowers produced by *Fritillaria pluriflora*. I am under the impression that this is a Californian species, but as it is not to be found in the usual works of reference one is unable either to confirm or correct this without rather prolonged search. It is a very distinct Snake's-head Lily with pink or red purple flowers. Of the two sent one is considerably lighter than the other. Mr. Gumbleton kindly tells me that these are from bulbs planted at the foot of a wall in 1895, but which did not flower last year. *F. pluriflora* is a very distinct looking and pretty little flower, not at all like the best known *Fritillarias*, with its bright coloured, campanulate twin flowers.

In the same box also came a bunch of the new yellow sweet Violet, but as the obliging and discerning sender has appended a query to the word "yellow," it is evident that he has more than

grave doubts about the correctness of the word as applied to this flower. One can only agree with him in this, as the colour is in no sense described by the word yellow. A dingy buff-white, if such can be conceived, may perhaps express it better; and it will require some further progress still before we attain what some appear to desire—a true yellow sweet Violet.

The other box contained a charming set of cut blooms of seedling Hellebores or Lenten Roses, made all the more valuable for comparison by being accompanied by blooms of the parent flowers. They came from Mr. Joseph Mallender, gardener to Miss Mellish, Hodsock Priory, Worksop. Mr. Mallender is not only an enthusiastic, but successful seedling raiser, and the flowers he so kindly sent are very beautiful indeed. The pollen parent was a rather small bright purple Hellebore, and the seed-bearer a nice white one; and the seedlings sent exhibit the influence of both. The flowers are larger and better formed, and range in colour from white, through some charming shades of pale purple or pink to deep purple. They are before me as I write, and their varied colours and fresh foliage of pale to deep green induce one to pause now and again to have another look. Although posted on the 8th of March, and not arriving until the morning of the 10th, they were as fresh as when cut. This is probably due to Mr. Mallender's precaution in giving them "a cold bath for three hours before packing them;" and others who have to pack cut blooms of the Hellebores, which are notoriously bad keepers when cut, may find this precaution a valuable one.—S. ARNOTT.

CHEMISTRY IN THE GARDEN.

(Continued from page 207.)

WE see by what has been said about the formation of soils how by the action of water, carbonic acid, and oxygen the surface of the rocks has been pulverised and worn down into soil. We have also seen how the quartz in granite and the silica in minerals like augite form sand, and how by the decomposition of the other minerals the silicates of alumina combine with water and form clay. The pieces of rock broken off the mass by the action of frost would intermingle with the clay and sand and give to soil thus formed certain properties. If the broken pieces were large they would form stones, if very small they would have the same properties as clay, while those of an intermediate form would be more like sand. By the decay of the lichens, mosses, and weeds a certain amount of decaying vegetable matter would be produced, which together with the substance formed by the decay of worms and other kinds of animal life, would form the material known as humus.

THE COMPOSITION OF SOILS.

Soils are, therefore, made up of two principal parts, (1) the mineral or inorganic, which consists of clay, sand, mineral fragments (stones), and sometimes carbonate of lime; and (2) the organic, which is the portion derived from the decay of vegetable and animal matter.

Pure clay is a substance known as hydrated silicate of alumina; or in other words it is composed of water, silica, and alumina chemically united. Pure clay would be of no value to plants, because it does not contain any constituent of use to them as food. The clays, and clayey soils in our gardens are not pure, but consist of a mixture of pure clay, silicates of alumina, tiny particles of rock, sand, organic matter, and compounds containing nitrogen, potash, soda, lime, magnesia, phosphoric acid, sulphuric acid, chlorine, and iron. Clay was first of all formed by the disintegration of the primary rocks, the particles of which settled down in the ocean to form the sedimentary rocks—slate and shale. Clayey soils of the garden may therefore be formed by the action of the various disintegrating agents, either from the primary, slatey, or shale rocks.

Pure sand is composed of two elements—viz., silicon and oxygen. This substance is, therefore, of no value to plants as food. Sandy soils always contain some clay, organic matter, mineral fragments, and compounds containing all the ingredients necessary for plant life. There is present, sometimes, in sand a large quantity of fragments of the mineral mica, when it is called a micaceous sand. Other sands contain large quantities of the ground shells of fish, and these would be known as calcareous sands. The mineral fragments (stones) are portions of rock that have been broken off the mass by the action of frost. They are generally similar in composition to the rock from which they were produced.

Carbonate of lime is never very abundant, unless the soil has been formed from chalk or limestone rocks. Humus is an organic substance, made up chiefly of carbon, hydrogen, and oxygen. It also contains a moderate amount of organic nitrogen, and smaller

quantities of the other elements, which are essential for the growth of plants.

We often hear the question asked, Is it possible for gardeners to analyse their soils? To this question we must answer No, except the gardener possesses a knowledge of analytical chemistry. He can with ease, however, make a mechanical analysis of his soil, and by this means will be able to determine how much sand, clay, stones, and humus his soil contains. Before dealing, therefore, with the elements of plant food in soils, we will give a brief description of the way a mechanical analysis can be carried out.

MECHANICAL ANALYSIS OF SOILS.

Select an average sample of soil, and after breaking it up as fine as possible, spread it out to dry. As soon as it is dry mix well together, so as to get an even sample, and then weigh from the heap 25 ozs. The 25 ozs. of soil should then be passed through a very fine sieve, so as to remove all the stones. If there be any soil adhering to the stones it must be carefully removed, and any pieces of root found remaining in the sieve must be returned to the sifted heap. When the stones have been taken away, the soil should be shaken up with rain water. After agitating the water and soil vigorously for a time, allow the vessel to remain stationary for a few minutes to permit the sand to settle, and then pour off the muddy water. By repeating this process several times, the operator will ultimately have all the mud or clay in one lot of water, and the sand in another. Now let the two vessels stand until the clay and sand have settled, then carefully pour off as much of the water as possible. The two vessels should next be placed in a moderately hot oven to allow the sand and clay to get perfectly dry, when they, as well as the stones, can be separately weighed.

When the clay and sand have each been separately weighed and the weights carefully noted, mix the two substances together again, and spread them evenly on a thin iron plate. The plate should then be placed over a fire and kept red hot for a few hours, care being taken not to allow any of the particles to blow away. As soon as the soil has burnt sufficiently, which is best determined by the change from a dark colour to a reddish hue, it should be removed from the fire and allowed to cool. The burnt sand and clay should then be weighed, and what they have lost by burning is organic matter. If the operation has been carefully carried out, the operator will know the weight of stones, sand, clay, and organic matter in his soil. One of the many soils we have subjected to a mechanical analysis gave the following results:—Stones, $\frac{1}{2}$ oz.; sand, 21 ozs.; clay, $2\frac{1}{2}$ ozs.; and organic matter, 1 oz.

The carbonate of lime is more difficult to determine than the sand, clay, or organic matter, because the quantity can only be obtained by a chemical analysis. A simple method of determining whether a soil contains much or little carbonate of lime is to pour diluted hydrochloric acid on to it. If a brisk effervescence follow it denotes that there is plenty of carbonate of lime in the soil; if a feeble, only a small quantity.—W. DYKE.

(To be continued.)

GROWING MARIGOLDS FOR EXHIBITION.

MARIGOLDS are common plants, and easily grown if you are not particular about the results; but these I wish to write about are the African and French types, which are grown extensively by cottagers and amateur gardeners for the smaller flower shows; yet how poor is the result! and from many reasons. Firstly, they start with cheap seeds which can be bought wholesale at next to nothing per lb.; secondly, they grow too many and spoil the plants before transplanting into the open ground; and finally they plant in unsuitable places.

To grow Marigolds successfully the following routine must be followed, when excellent results will be attained. About the middle of April sow the Marigold seed thinly in boxes and place in gentle heat; about 60° will suffice. As soon as the seedlings are 2 inches high transfer into a cold frame, and in a few days transplant them 4 inches apart in a shallow frame. After rooting they will require abundance of water, and should never be allowed to get dry. When the tops of the plants touch the glass, as they probably soon will do, raise the lights with a brick at both ends, on fine days removing them altogether; but be sure to replace at night, for Marigolds are tender plants, and easily spoiled by a slight frost.

For African Marigolds prepare a bed and dig in some well-decayed manure, making the soil as rich as for double Dahlias. Lift the plants with a mass of soil and roots from the frame, and plant with a spade, placing the plant into the ground up to the first leaves. They will make roots all up the buried stem. Eighteen inches apart is a good distance, while when they attain 18 inches in height they must be secured to a good stout stick. Thin out the branches to three, and remove all buds but one on each shoot. Some of these will be single, for although saved from the most double flowers some plants produce all single flowers. If the buds were left long enough the single flowered plants could be detected, but then it is too late to get the best results, so it is preferable to find you have a few single flowers than run the risk of losing your

show blooms. When the buds are thinned mulch with manure, and feed twice a week with good liquid manure, for Marigolds are gross feeders and will take the most generous treatment.

When the buds show colour they must be protected by a box of some kind having a glass top, which brings up the colour, and the centre, for to be a perfect bloom the centre must be high and the bloom smooth and circular. When the flower is being shaded the stem must be secured to a separate stake, so that it cannot beat against the shade, the flowers being easily bruised. In staging African Marigolds for show white paper collars are often used, but that is optional. The usual size of board is 5 inches from the centre of each hole, but if the foregoing cultural instructions are carried out they may be exhibited on Dahlia boards, for this is the way the writer often shows them.

The stem of the flower being large and hollow it is difficult to get them to sit well in the water tubes. This may be circumvented by having two opposite holes just under the rim of the tube, and running a pin or wire through the stem; this fixes them safely. There are only two varieties worth growing, Prince of Orange and Lemon Queen; the lemon-coloured flowers do not grow to so large a size as the orange. African Marigolds make splendid showy border plants if grown as above, without thinning and shading.

French Marigolds require the same treatment whilst in the seed beds, but when ready to plant out they must be treated exactly opposite. Select a poor piece of ground on a bank sloping to the sun, and plant a foot apart, and when in flower draw out those with single flowers. A perfect French Marigold should be high in the centre, full, and double, the petals overlapping each other, and each petal be half yellow and half darkest maroon. They are usually shown on green stands with white paper collars, but in the south no doubt this would be prohibited. The holes in the board are 3 inches apart from centre to centre.

The French Marigold is perhaps the most variable plant in existence, sometimes producing the most enchanting flowers and others in dull weather running all to self. The flowers should be cut when dry, as if cut in the wet the colours will often run. A stand of forty-eight perfect blooms is one of the brightest things in a flower show, and always attracts attention. There is only one really good strain in existence, nearly all the exhibition flowers being drawn from it. It is worse than useless to plant Marigolds under trees, especially the French; they are always a failure.

The Scotch Marigolds or Calendula are fine for beds and cut flowers. They are so durable in a cut state, lasting quite fresh for a fortnight, as also will the French type.—S. J.

FUNERAL OF THE LATE DR. HOGG.

As was indicated on page 235 would be the case, the remains of the "dear old Doctor" were interred in the London Necropolis Cemetery at Brookwood on the 18th inst.—the date of the last issue of the *Journal of Horticulture*. The funeral cortège left the residence of the deceased soon after 11 A.M., the funeral train being announced to start from Waterloo, the terminus of the London and South-Western Railway, at 11.45. There was, however, a little delay, but as the train ran direct to Brookwood without a stoppage it arrived in the Cemetery by the appointed time—one o'clock. The distance is only twenty-eight miles, but funeral trains do not travel at high express speed.

The funeral was essentially private, and was attended by few persons beyond the members of the family, in fact few could have known of the arrangements before they were being carried out. It may be said that last Thursday was a peculiarly quiet day at Brookwood, only four funerals from London, whereas on the next day—Friday—forty were arranged for.

Apart from the relatives and the nephew of the Doctor (the Rev. Alexander Rodger of Prestonkirk, who officiated), there were only present on the mournful occasion Rev. W. Wilks of the Royal Horticultural Society; Mr. William Paul of Waltham Cross (one of the Doctor's oldest associates), Mr. A. Rivers of Sawbridgeworth, representing his father, Mr. T. Francis Rivers; Mr. Herbert J. Veitch, Chelsea, representing his uncle, Mr. Harry J. Veitch, who is on the Continent, both personal friends of long standing; Mr. Arthur W. Sutton, Reading, who ascertained the necessary particulars by telegram just in time to reach the cemetery; Mr. Owen Thomas, Royal Gardens, Windsor; Mr. J. Wright, editor of the *Journal of Horticulture*; Mr. F. Broomhead, editor of its offshoot, "Poultry"; Mr. D. Morgan, and Mr. J. Chambers, heads of the advertising and printing departments respectively at 171, Fleet Street.

Expressions of regret of inability to attend were conveyed by Sir Trevor Lawrence, Bart., Philip Crowley, Esq., Rev. H. H. D'Ombraim, Dr. Masters, Editor of the "Gardeners' Chronicle," Mr. George Gordon, Editor of the "Gardeners' Magazine," Mr. H. J. Pearson, and the veteran Mr. Robert Fenn.

The coffin was entirely covered with beautiful wreaths contributed by the members of the family and friends, including Dr. Masters, Mr. Veitch, Mr. and Mrs. W. Paul, Mr. and Mrs. Arthur W. Sutton, Mr. Owen Thomas, the editorial staffs, and by the employees of the Fleet Street office.

After a violent storm in the morning the weather was fine until the procession formed in the cemetery, when another storm burst, and the chapel proved a haven of refuge indeed. The calm came quickly during the service for the grave-side proceedings; the coffin was lowered deep down into its sandy bed, strewn with flowers, the sand in due time returned to its position, and the mound encased with the wreaths sent as tributes of love and esteem by relatives and friends.

The Doctor rests by the side of his son who died in infancy, and on

the other side lie his father and mother-in-law, in the Milligan-Hogg burial ground in a pleasant position in this great Surrey cemetery. The railway passes into it between Laurel hedges; Rhododendrons and Hollies luxuriate in the sandy peat soil, and large specimen Wellingtonias and other Conifers are thinly disposed over apparently scores if not hundreds of acres of grass land and Heather, the whole resembling a gigantic pleasure ground—a beautiful resting place of the dead.

THE LATE DR. HOGG.

By the death of Dr. Hogg the horticultural world loses one of its greatest, most distinguished, and most honoured representatives. More than fifty years ago (I think in 1844) I first met Dr. Hogg in my father's nurseries, and from that time onward to the present we had been warm friends—a long and uninterrupted friendship of some fifty-three years, a friendship more firmly cemented as time went on. Not very long ago, when lamenting the death of a mutual friend, he remarked, "We know it is a condition of our existence here, and the loss of one friend should make us value more highly those who remain; in fact, bind us closer together."

The comprehensive and admirably written account of him by Mr. Wright in the *Journal of Horticulture* of last week leaves little for his other friends to say. Although a Fellow of the Linnæan Society, possessing considerable knowledge of the natural sciences, it is on his authority as a pomologist that his fame principally rests. The "Fruit Manual" (which has gone through several editions) is a work of rare merit, both from its completeness and general accuracy, and must have cost the author a considerable amount of labour. There is no book on the subject in any language to compare with it. The *Journal of Horticulture*, of which he was for many years co-editor with the late G. W. Johnson, and latterly sole proprietor, is a weekly serial on horticulture known and highly valued wherever the English language is spoken or read. Of his other works:—

For a few years I was co-partner with him and another valued friend, the late Mr. Thos. Moore, in the "Florist and Pomologist," founded by the late Edward Beck in 1848, which as an illustrated shilling monthly ran a useful and prosperous career of thirty-seven years. During our many meetings the Doctor's abiding thought was how to make the work as useful as possible. Suggestions for increasing the circulation or piling up advertisements were looked coldly on unless they tended to this end. The "Vegetable Kingdom" is also a work of great labour, and full of useful information. An essay on the "Dahlia" is also valuable, and was the book on the subject in its day. "The Gardener's Year Book," appearing annually, and the "Apple" and "British Pomology," the two latter being forerunners of his great work "The Fruit Manual," were valuable works of reference. These works I know and value, and there may be others which have not come under my observation.

Of his active work in life, I think Dr. Hogg did more than his share, and he did it well. There has been scarcely any important horticultural movement during the past forty years in which he has not been a conspicuous figure, and not a figure only, but a steady, thoughtful, and successful worker. In 1854 Mr. Thos. Rivers, of Sawbridgeworth, in a letter to the "Florist" (page 108) of that date, suggested, in conjunction with Mr. Spencer, of Bowood, the establishment of a Pomological Society. The idea was at once adopted, Sir Joseph Paxton becoming President, and Mr. Ingram, of Frogmore, being one of the Vice-Presidents, the Society being called "The British Pomological Society." This Society drew to it most of the first fruit growers of the time, and did useful and important work till 1860, when it virtually became the Fruit Committee of the Royal Horticultural Society. During its entire existence Dr. Hogg was really the head and heart of it, although he never put forth any claim to all the credit he was entitled to. He was for a time its Secretary, and wrote many of the reports of its meetings and notices of the exhibits, and was eventually one of the Vice-Presidents.

Dr. Hogg was for many years one of the most active members of the Royal Horticultural Society, first as Secretary and afterwards as Chairman of the Fruit Committee. His wide knowledge of fruits and genial manners made those meetings both profitable to the community and pleasurable to those who became associated with him. In 1866 the International Horticultural Exhibition and Botanical Congress was held in London, the Secretaries appointed being Dr. Hogg, Dr. Masters, and Mr. Thos. Moore. Three more efficient men could not have been found, and the grand success of that movement has always appeared to me to be largely due to the judgment, energy, and zeal of its three Secretaries. In the succeeding foreign international exhibitions which took place at St. Petersburg, Amsterdam, and Brussels Dr. Hogg was again a distinguished official.

But his interest in nature and society was not confined to horticulture and botany; he had read much in every branch of natural history, and numbered among his friends and acquaintances some of the highest and most cultivated members of society. The most prominent features in his nature always appeared to me to be an earnestness of purpose and an innate love of truth. Finesse and intrigue he was an utter stranger to, and instinctively shrank from those who practised or favoured them. His wide knowledge on horticultural matters he was always ready to impart without any assumed superiority or prospect of self-interest. I recollect on one occasion, when rising from a committee-meeting, an over-zealous friend remarked that he had voted against his own interests. He replied, "Never mind; it was right." To young gardeners trying to fight their way up in life, and to gardeners generally, he was always ready with counsel and help given in such a way as not to raise a blush on the cheek of the most sensitive.

We were rivals in one point only—the formation of a horticultural library, but in this each took a pleasure in informing the other of the when and whereabouts of any new or scarce book. Once in conversation I mentioned that I had been looking for an old book unsuccessfully, when he said he had two copies of it and I was welcome to one of them. It would be easy to write more, but with me it would only be a repetition of what has been already well said. Many of us will miss him sadly in the future, and those who knew him most intimately will say with most fervour, "Verily in him a good man has gone to his rest." But there is some consolation left for those who loved and esteemed him that, "To live in others' hearts is not to die."—WILLIAM PAUL, *Waltham Cross*.

MAY I be allowed, as one of the late Dr. Hogg's oldest friends, to add my testimony as to the sterling worth and many admirable qualities, which were perhaps not so apparent to the public as might have been expected, owing to his singularly unobtrusive and amiable character. This quality led him to keep his undoubted talents often in the background when associated with colleagues, many of far less mental calibre than himself, perfectly contented so long as the object in view was done, and fairly well done.

Dr. Hogg's connection, as Technical Editor of the "*Herefordshire Pomona*," a circumstance omitted in Mr. Wright's life-like and otherwise exhaustive obituary notice, bears out the above statement—a work enriched from the accurate and reliable stores of the "*Fruit Manual*," but sadly impoverished and lessened in value as the *Pomona* of the century, by the absurd discursiveness and foreign matter arbitrarily introduced by the local editor.

Among the many excellent traits in Dr. Hogg's character, none struck me more than the lively interest he took in the young, and the readiness with which he placed his time and talents at their service. My two sons would, I feel sure, be the first gratefully to acknowledge the great debt they owe to "the dear old Doctor" on their embarking some years ago, in all the sanguine inexperience of youth, on their present prosperous career.

A few almost illegible lines in pencil, beginning a letter kindly finished, by his daughter, which I received early in the year, now lies before me, as the last memento I possess of my revered friend; but his genial good humoured face, his kind voice, and manly presence—these will never be things of the past, but fade out of memory only with life itself.—THE HEREFORDSHIRE INCUMBENT.

THE last number of the *Journal of Horticulture* was a very reminiscent and reflective one—the leader; our old friend Robert Fenn's characteristic autobiographical notes; your most affectionate and touching tribute to our late chief; and the sympathetic references to him and of him by "D., Deal," and L. Castle, all strike the chord of reflective memories and tender appreciative condolence.

They also cause us personally to look within ourselves, and specially we who have been readers of and sometime contributors to the *Journal of Horticulture* for thirty or forty years, and make us, as first one great name amongst us and then another disappears, ask ourselves that intensely serious question, Who next? The personality of the "Doctor" in the horticultural world has been a notable one—quiet, industrious, reliable, patient, genial. We of the *Journal of Horticulture* know of all these attributes, but especially the last one, for it is that element of geniality pervading our *Journal* which has made it more like a family paper—a paper where all meet as brethren, members of a united and loving family than a mere professional journal recording gardening matters simply as a question of business.

We owe this, in large measure (at least so I believe) to the gentle, paternal influence of our late head. It is difficult to write just what one feels. We British people feel intensely, but just because of that intensity of deep feeling, we are curiously reticent of speaking of those feelings to the world at large. However, our revered friend is now sleeping his last long sleep, the sweet sleep which He gives to His beloved, and he has gone to it with, as Macbeth says, "Those things which should accompany old age, as honour, love, obedience, troops of friends."—N. H. POWNALL, *Lexon Hall Gardens, Nottingham*.

WITH feelings of deep sorrow I desire to express my great regret at the removal from our midst of a gentleman whose name has been a household one in gardens, and will ever remain familiar to gardeners of all classes, his "*Fruit Manual*" being an enduring memorial of a great mind, keen in observation, and unremitting in effort to make clear, in a scientific and practical manner, the results of great experience. The knowledge thus placed at our command merits the expression of highest estimation and deepest gratitude on the part of all interested in "gardeners and gardening."

Though connected with the deceased gentleman in respect of the *Journal of Horticulture* for exactly thirty-six years, I have only seen him twice, when I received such cordiality of reception and heartiness of hand-shaking as to leave an indelible impression of his deep sympathy with the craft, however humble the member, and of liveliest interest in the profession, with unsparing effort to promote its welfare.—G. ABBEY.

It was not till I opened my copy of the *Journal of Horticulture* last Friday morning that I learned the sad tidings of the death of Dr. Hogg, whom I greatly revered, and whom for five years I have regarded in the light of a very kind friend. The mournful news, however, was not unexpected. Not long previously I had learned from his friend of fifty

years, Mr. William Paul of Waltham Cross, that the venerable Dr. was in a critical and dangerous condition.

It was at Mr. Paul's beautiful place in Hertfordshire, Waltham House, formerly the residence of Anthony Trollope, the eminent novelist, that, through the thoughtful kindness of the great horticulturist, I first became personally acquainted with the consummate pomologist. I was on that occasion, when accompanying him through the nurseries, much impressed by his charming simplicity of manner, his utter absence of all assumption, the small importance he seemed to attach to all the knowledge he possessed, and especially by the peculiar amiability and affectionateness of his nature. Reverence was one of his noblest characteristics. To him, as to Cowper, Nature in all her myriad manifestations of manifold beauty and infinite expressiveness, was but a name for an effect, whose cause was God.

It was easy to see that by Mr. Paul and his family he was, in virtue of those attributes which I have endeavoured to indicate, greatly beloved. Nor can I wonder at this when I remember his many kindnesses to myself. Immediately after that memorable visit to Waltham he sent to me as a present his comprehensive "*Fruit Manual*," with a characteristic inscription on the title page, a work which was to me a marvellous revelation of the capabilities of human knowledge, and which will ever remain one of my most treasured and precious possessions.—DAVID R. WILLIAMSON.

ON opening the *Journal* last week (March 18th) a feeling of deep regret took possession of me on reading of the death of Dr. Hogg, the conductor of this paper for so great a period of time. To many gardeners who, like myself, have read the *Journal* for many years the name of the great pomologist has been as a household word to them. His labours in the science of fruit culture and nomenclature has been immense, to say nothing of the secretarial work with that splendid international exhibition of May, 1866, held at South Kensington, the like of which, I should say, has not been seen since. His work and support in connection with the Royal Horticultural Society deserved the gratitude of all the gardening community, for anyone who read the reports of meetings at South Kensington twenty years ago or so could well see that the Doctor's support was on the right side—that of horticulture.

He was a gardener's true friend, and many of the craft has had cause to be grateful for the interest he has taken for them. I for one have. It was my privilege on one occasion, now some years ago, to see him in his study at his London residence, and his kindly words and advice to me on that occasion, just then entering upon a new situation, I have never forgotten. His decease, after such a long and honourable career, is a loss to the horticultural world, but his works on fruit and other subjects will live long after him.—A. HARDING, *Orton*.

MAY I join in the expression of regret at the sad news of the death of Dr. Hogg? My acquaintance with him was limited to correspondence connected with the *Journal*, but it was sufficient to give me a high idea of our lost chief's kindly nature. From one and all connected with the *Journal* with whom I have come in contact I have ever experienced the greatest of kindness, and the good Doctor, to the best of his ability, helped to form and strengthen the feeling of friendship. Even a brief note, which, in the hands of many, would have been confined to its bare subject matter, would contain a few friendly words appreciated at the time, but doubly prized now when the hand, feeble as it was even then, which penned them is now at rest. Small is the pebble I can add to the cairn raised in memory of Dr. Hogg, but it is the offering of respect and sorrow.—S. ARNOTT.

IT was with deep regret that I learnt of the death of my old acquaintance, Dr. Hogg, when I opened the pages of the *Journal of Horticulture*. His memory will ever be associated with the much appreciated intercourse I once had the privilege of enjoying with him at a Fruit Conference held at Hereford, when he kindly invited me to assist him in the awards, and I treasure the copy of the "*Fruit Manual*" he subsequently presented to me. I have a vivid recollection of receiving his genial greeting, alas! for the last time when at the Temple Show last year. I perused with deep interest the sympathetic memoir of our dear old colleague; the perusal of it also deeply affected my wife, who also had ever cherished a feeling of high regard towards Dr. Hogg. The Rev. H. H. D'Ombra's and Mr. L. Castle's tributes of the lamented Doctor in the *Journal* must have embodied the sentiments of scores of friends and readers of the *Journal*.—WILLIAM GARDINER.

I FEEL I must express my sorrow and regret at the death of Dr. Hogg. He has had a long life, and spent it well in the interest of horticulture, as evidenced by his well-known works and the long conductorship of the *Journal of Horticulture*.—E. D. SMITH.

LAST week's issue of the *Journal* will be read with a particularly sorrowful interest, and will occasion a widespread, silent, sympathetic sorrow that will be deep and sincere. I am sensible of my inability to express what I would say in tendering my condolence at such a time as this; but the memory of him will be refreshed by kindly remembrances.—JOHN E. JEFFERIES.

IT was only on opening the *Journal* on Friday that I learnt the sorrowful news of the dear old Doctor's end. Even though meeting him but occasionally, as I did, one could not be unmoved at the loss of so kindly and loveable a friend as he has always been through many years.

It is a source of much regret to me that I did not learn of the event in time to pay a last tribute of respect to his memory by attending at the interment; but the recollection of his invariable kindness and consideration will always be held in grateful remembrance.—GEO. SHAYLER.

OLD friends can never be replaced, and old comrades and fellow workers when taken away leave a sad gap. We miss the cheery intercourse, the bright smile and pleasant word, and life seems poorer and duller. In our old friend's case we have the satisfaction of knowing that his life's work was well done, and that he had earned his rest. He had made for himself a distinguished name—not as a warrior or artist, but as a gentle craftsman, on the lines of our common ancestor, "the grand old gardener." He has gone to see the immortal flowers, that are untouched by blight, and feel no nipping winds and cutting frosts; and while we think tenderly and sadly of him, we will rejoice at his safe arrival in the land where there is no more pain. Our sympathies are with all those who have lost in the good old Doctor a true friend.—HELEN GRACE.

[Kindly references are also made by Mr. David Thomson, Mr. John Thomson, Mr. G. W. Summers, Mr. A. Pettigrew, and incidentally by many other correspondents. We have been compelled to abridge some of the communications above inserted.]

WEATHER IN LONDON.—Though not quite so much rain has fallen during the past week as was the case in the previous seven days, the weather has not been wholly favourable. Several days have been wet in the mornings and finer after noon and in the evenings. Tuesday was a lovely day, the sun being bright and very warm. On Wednesday practically the same conditions prevailed.

— WEATHER IN THE NORTH.—A great deal of rain has fallen during the week ending the 23rd, no day being fair throughout, and squally winds have been frequent. Sunday was pleasant. A westerly gale rose on the afternoon of Monday and continued throughout the night, but fell towards morning. There is much need for dry weather, especially for lands where Beans are grown.—B. D., *S. Perthshire*.

— ERICA MEDITERRANEA HYBRIDA.—For a bright display in spring this plant has high qualifications. The bright red flowers commence to open early in February, and continue to do so until the end of March. From general appearances, at first sight this plant might easily be taken for a tall-growing form of *Erica carnea*. On closer examination, however, the flowers are found to be produced in longer spikes, and the habit of the plant is more free generally. It is, however, dwarfer, and appears to flower earlier than the typical *Erica mediterranea*. General appearances suggest it to be a hybrid between *E. mediterranea* and *E. carnea*.—W. D.

— INFLUENCE OF WIND ON TREES.—There can be no doubt but that where trees are properly secured wind exercises upon the stems and branches healthful effects. The motion created by the wind, and this is invariably the most excessive when trees are leafless, serves to harden the woody fibre and to help in developing cellular tissue. Fir trees during winter no doubt do hold much wind and are in hurricanes severely tried, but generally the harm wrought amongst these by gales of wind is very much less than would have been the case were the ordinary deciduous trees in leaf. Possibly the turpentine, always so plentiful in Fir trees, renders the wood more tough, and to use a common term lissome. True, Fir branches will snap sharply under an undue weight of snow, but that is pressure very different from the lateral pressure of wind. A very curious effect of wind pressure is sometimes seen in open places where south-west winds blow strongly and unbroken, especially on fruit trees. In these cases all the head growth seems to bend towards the north-east, and no sun force seems capable of bringing it back into its normal condition. Aesop in one of his fables represents the sun as being more potent in removing the traveller's cloak than the fiercest wind, but it is evidently not so in the case of trees. On the other hand, where fruit trees are somewhat sheltered from winds, the sun then does exert great attractive power. At this moment of writing a fierce hurricane is blowing, and one's thoughts are turned naturally to the newly planted trees of all sorts, with sympathy for those whose needful supports have not been furnished.—A. D.

— GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Mr. H. Morgan Veitch has forwarded to the Secretary of this Institution a cheque for £60 2s. 2d., being the net proceeds from the performance of the comedy-opera "Dorothy" at St. George's Hall in aid of the "Victoria Era Fund."

— LONDON ALMOND TREES.—These trees, which have been freely planted in suburban gardens, especially perhaps in the south and western parts of the metropolis, are now in full beauty. Owing to the absence of east winds the flowers are larger than usual, they are also borne in such profusion that the trees resemble gigantic silvery bouquets.

— SPRING BLOOMING SHRUBS.—The great value of early blooming shrubs is now manifest, for even whilst the March weather is often cold and stormy yet we see the various beautiful and golden flowered Forsythias coming into abundant bloom, and even in cold and somewhat exposed positions making shrubberies gay. The scarlet Ribes is coming rapidly into bloom, and the deeper coloured *Pyrus japonica* is already rich in colour. Very pretty also are the various forms of *Daphne Mezereum*. The very early *Azalea japonica* has been flowering for some time. This very early variety ought to be planted in clumps, and where some shelter from north winds is furnished. In proper soil and in shelter various of the earliest blooming hybrid *Rhododendrons* have long been blooming abundantly, and the pretty *Andromeda* and *Laurustinus* are pleasing. Because other hardy flowers are yet so few, all the more should we encourage early blooming shrubs.—D.

— HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—At a meeting of the above Society, held in the Parish Schoolroom on Tuesday, March 16th, a paper was read by Mr. F. Mason, gardener to A. Smith, Esq., West Hill, on "The Narcissus." The essayist would like to see these beautiful bulbs more generally cultivated in this country than is at present the case; he does not see why Dutch produce should monopolise the English markets when they can be grown as well, if not better, by Englishmen. He set forth the many and various ways in which the *Narcissus* can be utilised, both inside for pots and outside for borders, flower beds, on grass, round trees, ornamental water, rockeries, and many other places, in which the plants thrive and produce masses of bright golden flowers so acceptable during the early spring months.—F. L. T.

— TOP-DRESSING LILIUMS.—Where *Liliums* have not been repotted or top-dressed in the autumn the benefit accruing from a liberal top-dressing at the present time will be apparent, not only by the vigorous growths made during the coming summer but also the improvement in the flowers, and will in many cases put weakly bulbs into good condition for repotting in the autumn. Our pots are just being lifted out of a plunging of coal ashes in a cold frame, and the top-dressing which was applied last October is almost a mass of white fleshy roots, which will again receive another supply of fresh material previous to their being placed in a cool house. In top-dressing remove as much of the old soil as possible, and fill in with a compost of good fibry loam two parts, and one each of red sandstone broken up and horse droppings, making moderately firm. We find no compost to suit us better.—GROWER.

— THE GARDENERS "UNITED."—The fancy for shortened titles has led to the calling of the United Horticultural Benefit and Provident Society by the above pithy appellation. May the members always be as united in spirit and in practice as they were when I had the pleasure to preside over their annual meeting on the 8th inst. Recently I attended in London also an annual general meeting of another well-known Society, when the large room was full of foul tobacco smoke, the members seeming incapable of transacting a couple of hours' business without smoking. To enjoy themselves in that way is one thing; to inflict an abominable nuisance on other members who do not smoke, and who have the fullest right to be present, is quite another. Possibly the *Chrysanthemum* temperament is of so excitable or irritable a kind that it cannot be brought calmly to discuss business matters unless under the influence of an anodyne. What a striking contrast was the conduct of the members of the "United." They sat out a couple of hours, many having previously had an hour's attendance in Committee, without even thinking of smoking; and I did not see that one member seemed irritable in consequence. Thousands of business meetings are conducted in this country, and thousands of gatherings and functions take place without the introduction of this undoubted infliction upon those who do not indulge in the habit. Until the *Chrysanthemum* men learn better manners they will not see me at their meetings again.—A. D.

— **BULBS AND CUT FLOWERS.**—Mr. H. B. Greenfield writes:—"I am particularly anxious to ascertain the total value of bulbs imported into London annually, and also the total value of cut flowers at Covent Garden. Can any reader help me? I should esteem any information."

— **AZALEA INDICA ALBA.**—In looking through our single white Azaleas I fail to find one so pure in its snowy whiteness as the old but ever useful Azalea alba, where it can be easily distinguished from any other variety. True, it is not such a quick grower nor does it possess the handsome foliage of many of the newer varieties, but when we come to its blooming qualities, its lasting properties when cut, and its value to those who have to keep white flowers for wreaths and crosses, we must have something good ere we can part with an old and tried friend. —**FLORIST.**

— **BIRMINGHAM GARDENERS' ASSOCIATION.**—Under the title of "Bulb Culture in England," Mr. W. Spinks read a paper contributed by Mr. F. W. Burbidge, Trinity College Botanic Gardens, Dublin, in the presence of a good assembly, presided over by Mr. W. B. Latham. Considering his well-known, intimate knowledge of bulbous plants, and of the essayist's graphic and facile pen, it may be readily assumed that the reading of the paper evoked the deepest interest, and resulted in an interesting discussion. [An instalment of Mr. Burbidge's excellent and suggestive paper appears on another page.]

— **PRESERVATION OF FLOWERS.**—The following is a very old method of keeping flowers without loss of colour. Dry some very fine, pure silicious sand in the sun or oven; then take a wooden, tin-plate, or pasteboard box sufficiently large and deep, and place your flowers inside erect; then fill the box with sand until this last is about an inch above the top of the flowers. The sand must be run in gently so as not to break the flowers. Cover the box with paper or perforated cardboard, and place it in the sunlight, oven, or stove, continuous heat giving the best results. After two or three days the flowers will be very dry, but they will have lost none of their natural brilliancy.

— **CINERARIAS.**—I have often wished that Mr. James of Farnham Royal, who always shows such wonderfully perfect Cinerarias in the spring, would put a dozen of his best varieties, of which stock is always kept, into the market. It would be interesting then to see how near to the same remarkable pitch of excellence seen in Mr. James' plants other growers could produce them. Big enough the blooms are certainly, and in substance, colouring, clearness of marking, and form no flowers could be better. I hope none will produce larger blooms. The exceeding dwarfness seen in the plants is partly due to the habit of the strain and partly to the cool culture given, with ample light and air. Those who grow Cinerarias for very early blooming must largely force, and of course the plants are drawn and the blooms somewhat demoralised. Strong feeding is a mistake, and should not be encouraged. Mr. James does not feed materially, and pots firmly.—**A.**

— **ROYAL METEOROLOGICAL SOCIETY.**—This Society has for many years past held an exhibition annually, which has been devoted to some special class of meteorological instruments. This year the Society has arranged an exhibition of meteorological instruments in use in 1837 and 1897, in commemoration of the Diamond Jubilee of H.M. the Queen. The exhibition, which was opened on Tuesday the 16th instant, is held in the large Library of the Institution of Civil Engineers, Great George Street, Westminster, S.W. The most interesting exhibit is a railed-off enclosure about 12 feet square, covered with green baize, representing a typical climatological station of the Royal Meteorological Society. The exhibition will remain open until Friday the 19th inst. In connection with the Royal Meteorological Society's special exhibition of instruments, a lecture was delivered on Wednesday evening the 17th instant by Mr. G. J. Symons, F.R.S., on "Meteorological Observations in 1837 and 1897." After describing some of the instruments in use at the commencement of the Queen's reign, the lecturer stated that he had collected all the known records of rainfall for the year 1837, and that he was able to give the total rainfall for that year from 161 stations. An account was then given of the meteorological instruments in use at the present day, reference being made to the barometer, thermometer, hygrometer, rain gauges, anemometers, self-recording instruments, &c. The methods adopted for registering the duration of sunshine, and the amount of evaporation were next described. Allusion was also made to the help which photography has rendered to meteorology, especially in relation to the forms and movement of clouds, &c. Mr. Symons concluded his lecture by exhibiting a map showing the state of the weather over Western Europe at 8 A.M. the same morning. The lecture throughout was illustrated by numerous lantern slides.

— **TADCASTER PAXTON SOCIETY.**—At the weekly meeting of the above Society, held on Thursday, March 18th, an excellent paper was read by Mr. Clayton, the Gardens, Grimston Park, on "Hardy Perennials." He described the formation of borders, situation, arrangement, and selection of suitable plants, propagation, and cultural routine. His remarks were listened to with very great interest. A very hearty vote of thanks was accorded to Mr. Clayton.—**J. S. S.**

— **THE WEATHER AND FRUIT PROSPECTS SOUTH OF IRELAND.**—The month of March so far has been very inclement, and the temperature uniformly low here. The snow is on the hills around, although it fell as sleet or wetted snow in the lowlands. Fortunately for tender opening blossoms such as Apricots, Peaches, and Nectarines on south walls, not protected, and Jargonelles and Early Rivers Plums in the open garden, there has been no frost in the south of Ireland during the month, presumably owing to the wind steadily veering between south and west. On three nights during the month here my outdoor thermometer registered 34°, perilously near the freezing point. At present all garden and farm land is saturated—so different from the customary dusty, dry, biting March winds. All crops must necessarily be backward. I cannot remember brighter fruit prospects on any former year if all goes well.—**W. J. MURPHY, Clonmel.**

— **NEW CLASSES AT SHOWS.**—I read with much interest last autumn the desire expressed by some of your readers for new classes at flower shows, and I think it may interest some to hear of two novel ideas which were carried out at a small exhibition held here last November. The first was a class for any design, with or without ribbon, not mentioned in any of the preceding classes. It called forth keen competition, there being thirteen entries. The first prize was awarded to a bridesmaid's staff with Chrysanthemums and bronze foliage with ribbons. Amongst the other entries there were several most attractive designs, including two tastefully arranged sets of table vases, a decorated banjo, &c. The other novelty was a special prize to be voted for by the visitors to the show, each visitor to receive one vote. This proved a great attraction, and the hour for the result to be known was waited for with great interest by all concerned. It was eventually awarded to the bridesmaid's staff, but it was closely run by another entry in the same class, and a very charming basket of Chrysanthemums.—**C. F. W., Fairford.**

— **GRASSENDALE SHOW.**—The seventh annual exhibition was opened in the Grassendale Parish Room, and was ahead of previous efforts. The Secretary and Committee are deserving of every credit for bringing about such a floral treat. There was an increase of exhibits this year; they numbered 140. The Staging Committee did their share of the work in a capital manner, and it is pleasant to record an excellent attendance of visitors. The principal prizewinners were Messrs. O. H. Williams, W. J. Davey, R. P. Houston, M.P., A. L. Jones, E. Pryor, W. C. Atkinson, E. Lawrence, W. B. Bowring, C. Langton, and Mrs. Duncan, their contributions being of the highest possible standard of merit. Perhaps the most noteworthy feature in the show exhibiting the highest culture was a splendidly grown Rose of Madame Berard, carrying fifty open blooms and the same number of buds. This was staged by the Hon. Secretary, Mr. Fawkes, gardener to C. Langton, Esq., Aigburth, and he had every reason to be proud of it. A large share of work was accomplished in a cheerful manner by Messrs. W. Blomily, J. Whitfield, A. Bryers, and E. Evans.

— **WOOLTON GARDENERS' MUTUAL IMPROVEMENT SOCIETY.**—On Thursday evening the Mechanics' Institute presented an unusually bright appearance on the occasion of the closing meeting of the session, when, as for many years past, the Committee had presented to the members and friends a rich floral treat, combined with an attractive musical programme. The new Secretary, Mr. R. G. Waterman, has always been to the fore in such work; he has laboured diligently to make the Society's undertakings a great success, and is deserving of the highest commendation. To one and all the meeting proved of the greatest interest, the charming spring flowers being greatly admired by the large number of visitors. The thanks of the Committee are due to the following gentlemen for their kindness in sending and staging such splendid exhibits—viz., Mr. Todd, gardener to Holbrook Gaskell, Esq., Woolton Wood; Mr. B. Cromwell, gardener to T. S. Timmis, Esq., Cleveley; Mr. J. Glover, gardener to Col. Walker, Gateacre Grange; Mr. Jellicoe, gardener to F. H. Gossage, Esq., J.P., Woolton; Mr. T. Carling, gardener to Mrs. Cope, Woolton; Mr. G. Eaton, gardener to Col. Shirley, Allerton; Mr. J. McColl, gardener to T. Hughes, Esq. The programme of music was most successfully rendered, and a balance of about £3 will be handed to the Victorian Era Fund.—**R. P. R.**

RHODODENDRONS AT KEW.

RHODODENDRONS, evergreen and deciduous, form one of the most striking of the many groups of beautiful hardy shrubs at Kew during spring. When the weather is mild, from the beginning of January until the end of June, one or more representatives of this charming genus of plants are to be found in flower. At the present time (March 9th) several very pretty species and varieties are to be seen in flower in the Rhododendron dell, and in the borders devoted to Ericaceous plants near the temperate house.

In the dell some of the most striking are *R. fulgens*, *R. Thomsoni*, and *R. Nobleanum*. The first-named is a most beautiful species with bright deep red flowers. Of this, Sir Joseph Hooker wrote, "This is the richest ornament of the Alpine regions of the Sikkim Himalayas." The individual flowers are about 2 inches across, and produced in closely packed medium sized trusses. It is figured in the "Botanical Magazine," t. 5317.

R. Thomsoni is also a native of the temperate Sikkim Himalayas. The flowers are fleshy in texture, blood red, drooping, 2 inches in length, by the same in diameter across the mouth, and produced nine to twelve together in loosely packed trusses.

R. Nobleanum is a red flowered hybrid, between *R. arboreum* and *R. caucasicum*, and besides being a useful garden plant it is interesting on account of its being the first to be introduced of the many fine garden varieties now in cultivation. Those in existence in the Ericaceæ collection all belong to the dwarf section. By far the most showy of the dwarf Rhododendrons in flower is *R. præcox*. Others to be seen are *R. dauricum* and *R. daphnoides* with rosy purple flowers, and *R. parvifolium*, a small species with purple flowers, interesting botanically but not otherwise.

In the winter garden several Rhododendrons are flowering. A large plant of *R. arboreum* is carrying about seventy trusses of bright red flowers. Several plants of *R. ciliatum* and the sweetly scented *R. formosum* are just coming into flower, whilst a plant of a charming dwarf Rhododendron, called Queen of the Dwarfs, is smothered with pure white blossoms.—W. D.

A GARDEN IN THE ISLE OF WIGHT.

[An Address (amplified) by Rev. H. EWBANK to the members of the Horticultural Association at Newport.]

(Concluded from page 188.)

ONE thing which I most earnestly recommend is an exquisitely lovely climber from Chili, *Mandevilla suaveolens*. It is nearly always grown in a greenhouse, and is classed among tender things, and few ever dream of giving it that measure of liberty which it knows so well how to use. According to the idea that protection and restraint are indispensable to it, I kept it for years under glass, and it filled up a large part of my greenhouse, to the exclusion of many other good things; but this is what happened to it—it blossomed and grew to a great extent, but it became infested with red spider and other abominations. I had the greatest possible difficulty in keeping it free from vermin; if it were beautiful and fragrant, as certainly was the case, it became a beautiful and fragrant nuisance, for it could be called nothing else. I therefore determined to try it in the open air, and to let it live or die, as it saw fit. To my great satisfaction it determined to live, and it got through the terrible frost of 1894-5, though it was cut down to the ground. It has since then quite come round, and it touches the eaves of my house again, and is strong and vigorous as before. Every building here with a suitable exposure ought to have this very beautiful climber. It grows immensely, and blossoms in July. It should be planted in April, and should not be pruned very much. It wants to have little more done to it than the excision of the weak and feeble sprays, and perhaps a slight protection in very hard frost may be given to it.

Another great triumph of the Isle of Wight and of my surroundings here is *Poinciana Gilliesi*; perhaps I may call it the best success I have ever had. It is a most beautiful flowering shrub with very nice foliage. The leaves are scattered, alternate and bipinnate, and the best part of the matter is that it seems to do better in the open air in my garden than it does in a stove or even its own native habitats. It is grown at Kew in a pot in the temperate house, and could not have been much more than 3 feet high when I saw it last. In fourth volume of the "British Flower Garden," by Sweet (which is a kind of sacred book among gardeners), these words occur about *Poinciana Gilliesi*. He says, "We have seldom so interesting a product as the present, and one so eminently deserving the attention of cultivators. It belongs to the order Leguminosæ, and grows on the banks of a river near Mendoza in South America. The flowers are large, yellow, in a terminal corymbose raceme; the petals are five, alternating with the calyx, nearly equal, sulphur coloured, an inch long, spathulate, slightly obcordate, wavy and crumpled, thin, many-nerved, longer than the calyx; the stamens are ten, separate; the filaments are long and slender, awl-shaped, bright red; anthers dark red." Sweet says his drawing was taken from a specimen which flowered in Mr. Knight's nursery, Chelsea, where the

tree has stood several years placed near the wall of a stove, which it overtops, and even exceeds the height which it attains in its own native country. No doubt this stove helped it very much, but here it had no stove at all. My thinking about it came from a remark which Canon Ellacombe made when we were talking together in his study more than twenty years ago. He said:—

"I should not be surprised if *Poinciana Gilliesi* would do well with you," and this turned out to be a very fruitful suggestion. I bought a packet of seed from Mr. Thompson, for which I gave fourpence, of Ipswich, and though I had to wait a long time for results I have been since amply rewarded. It was twelve years before any of my young trees blossomed, but since then the one I have here has gone on increasing amazingly in size year by year, and flowering with increasing profusion. It is now a picture of strength and beauty, and as its elegant foliage waves about in a very lightsome joyous manner it seems to say, "I have never given you a moment's anxiety in my life, and I never mean to give you one." But what it is coming to I cannot possibly tell. Already it is very nearly twice the size to which it attains in its own country, and it nearly touches the windowsill of the second storey in my house, and it is growing still. The eminent traveller and scientist, Mr. Alfred Russell Wallace, paid me a visit a short time ago, and he took a great interest in my beautiful shrub. He said that he was not surprised at its well-being at all—he should have expected it from what he had seen abroad. It is a matter of great regret to me that I have no specimens of *Poinciana Gilliesi* left to give away to my friends. I did give some away, and the others were lost, as I did not know their value in time.

Another handsome tree is *Paulownia imperialis*. It is very different from but nearly equal to the foregoing in beauty. It comes from Japan, and is by no means unknown in the Isle of Wight. There is a large one in the garden at St. Clare, and there are two or three at Ventnor. But it is possible that its great love of water may be new to some persons. In this respect it resembles the Quince. I had a specimen in my dry flower garden near the house for ten years or so, and it never did anything. I do not think it ever flowered in that situation, and it scarcely grew at all. As soon, however, as it was moved to the lower part of the kitchen garden, and was placed at the bottom of a slope, it altered all its performance at once; it increased in size as if by magic, and blossomed abundantly. The trunk of the tree is now nearly 4 feet in girth—before it was moved it was only like a thick stick. The flowers are Gloxinia-like and of a beautiful violet colour, and at a little distance one might fancy that a violet gauze had been spread over the tree. As it overhangs the Ventnor Road it is the commonest thing in the world to find carriages stopping close by it that the occupants may enjoy the sight; and though I do not know what they say to each other, they sometimes look as if they thought that they were gazing upon a vision which is not of earth, but of heaven. For the rest I can give little more than names. *Magnolias* ought to be much more grown in the Isle of Wight than is at present the case. I have some six or seven species and varieties, and some two or three of them are beyond all praise. *Exogonium purga* is a splendid climber, and year by year it touches the eaves of my house. *Choisya ternata* (fig. 55) is one of the best all-round shrubs I have. *Edwardsia grandiflora*, *Carpentaria californica*, *Xanthocereus sorbifolia*, *Plerostyrax hispidum*, and *Exochorda Alberti* are much to be recommended for this part of the world. *Camellias* are more hardy than Laurels. Sikkim Rhododendrons do very well indeed here if only they have some protection over their heads in a hard winter. *Ipomæa pandurata* would soon cover the whole place if it were allowed to have its way. But the enumeration must cease. Let me only say that if my remarks have proved anything they have tended to show that the Isle of Wight offers advantages which are of a very unusual kind.

We have a fringe or margin here for good which is by no means commonly known. *Narcissus triandrus*, *Poinciana Gilliesi*, *Rosa berberidifolia*, and *Mandevilla suaveolens* all unite in saying that gardening is carried on here with more of promise than can be easily found elsewhere. Of course I know there are losses to be endured. Who could expect it to be otherwise where so many trials are made? I have had the finest specimen of *Fremontia californica* in the whole country smitten to death by the sun, and soon after bleeding to death; but one must expect to put up with some adversity if after all the balance is right, and of that I am certain; and not only is it the case that so very many good things will consent to live here, but what is vastly important from one point of view is that the season for them is at least three weeks earlier than it is at Kew, and another thing is that the colours of the flowers are much brighter here than about London or in places which are more northerly still. I say, then, that we have every encouragement here for enterprise in our horticultural efforts, and I have often had a vision before my eyes as to what the Isle of Wight would become if it were really to be adorned with some attention and skill. Imagine for a moment how the Undercliff would look if it were properly taken in hand, and *Mandevilla suaveolens* were festooning itself over many a crag and *Poinciana Gilliesi* were to be common in villa gardens, and *Ipomæa pandurata* were allowed to reach the eaves of the houses, and soon in a thousand other ways that could very easily be given the aspect of the whole place would be changed and know itself again no more. It is a paradise now, but it would then be a Paradise eclipsed, and the Riviera itself would have no greater attraction to offer than might be found here.

A friend of mine and a very eminent horticulturist, Mr. J. F. Wilson of Weybridge and Wisley, was at Ventnor for his health's sake for some weeks last spring, and he very earnestly bewailed the let-alone condition

which he saw on every side. I think it gave him positive pain. "Fancy," he used to say as we walked along, "how well *Phormium tenax* would look there!" "There is the very best possible spot for *Osmunda regalis*." "Paulownia imperialis would be at home in this place

ways; but splendid they certainly are *not* by reason of the floral treasures which they contain. Let but only common justice be done to the Isle of Wight, and the Garden Isle would become worthy of its name in a far higher degree than is at present the case. An old Roman poet

FIG. 55.—CHOISYA TERNATA.

at once," and so on *ad infinitum*. He seemed grieved to find great opportunities thrown away, and almost the same thing might be said of many splendid gardens in all parts of the island, for splendid they very often are in point of natural beauty—the sea, and their environment in other

bewailed the apathy and indifference of the people of his day in words which are not at all out of place in this island:—"O fortunatos nimium, sua si bona norint agricolæ," for a free translation of them might run thus:—"Wake up to your privileges."

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL, MARCH 23RD.

THERE was another superb exhibition at the Drill Hall, on Tuesday last, when almost the whole of the available space was fully occupied. Each floral section was well represented by exhibits of the highest quality, though of course the bulk of the produce came within the province of the Floral Committee.

FRUIT COMMITTEE.—Philip Crowley, Esq. (in the chair); with Rev. W. Wilks, T. F. Rivers, J. Cheal, G. W. Cummins, A. F. Barron, T. J. Saltmarsh, G. Reynolds, F. Q. Lane, J. Smith, H. J. Veitch, G. Wythes, G. Woodward, A. J. Laing, C. Herrin, A. Dean, and J. Wright.

Scarcely any produce was sent to the Committee, but the meeting will be remembered by all who had the privilege of listening to what will be admitted as an admirable and appropriate speech in moving a resolution.

THE LATE DR. HOGG.—Mr. Wilks spoke as follows:—

Mr. Chairman and Gentlemen of the Fruit Committee,—We have all of us, I am sure, come here to-day with very contradictory feelings. We one and all want to get up and bear testimony to the great loss which this Committee has sustained since last we met; and yet we one and all shrink from doing so from a feeling (which I share with everyone of you) that there is not one among us capable of doing justice to the theme. In one sense, then, I shrink from the subject as from a task too hard for me to perform—a burden I am unequal to bear; whilst, in another sense, I feel that the duty which the Chairman has deputed to me is the greatest honour he could confer upon me.

Gentlemen, we have lost one whom all who knew him at all intimately loved sincerely; whom all at this table revered; whom every English gardener honoured; whom all pomologists in every country of the world looked up to and respected as the chief authority on fruit—our dear friend and coadjutor Dr. Hogg—the founder of this Committee—who has been taken from us.

But what a splendid work and what a grand example he has left behind! Seldom has it been given to a man to reduce to such (comparatively speaking) perfect order such an absolute chaos as he found British fruit description and nomenclature. The greatness of his work in this respect is not yet fully realised.

A Scotchman by birth, and like so many Scotchmen, of untiring energy and dogged perseverance; a man of transparent honesty of purpose and of blunt outspoken truthfulness; he hated hypocrisy and sham, whilst his heart was simply overflowing with kindness and gentleness and sympathy.

He was not like any other man. He had a very marked individuality; a sort of solidity and terseness of expression, both in word and manner, which was reflected in the picturesque ruggedness of his outward form, reminding one not a little of the massive, open, wind-swept, heather-clad hills of his own Scots land. No one who ever saw him could possibly forget him, or mistake him for any other; and no one who really knew him but now feels he has one staunch and true friend the less.

Gentlemen, we cannot but mourn for Dr. Hogg; but even whilst we mourn let us not forget to thank God truly for the man, and for sparing him to us for almost fourscore years.

I beg to propose the following resolution:—

"The Fruit Committee of the Royal Horticultural Society desire to record upon their minutes the profound estimation in which they hold the life and work of the late Dr. Hogg. The Committee recognise with gratitude that Dr. Hogg's life was one of unceasing benefit to the best interests, not only of British pomology, but also of the pomology of the whole world. Wherever fruit is grown for the benefit of mankind, there for generations yet unborn will the name of Dr. Hogg be known and honoured. The Committee can find no words to express the greatness of the loss which they in common with all English speaking fruit growers have sustained by the death of one whom all who knew him held so dear; they are forced to content themselves with placing upon record their deep sense of the inestimable privilege they have enjoyed in being associated on this Committee for so many years with so kindly and eminent a man."

The members uncovered during Mr. Wilks' speech, and the resolution was accepted in mournful silence.

What little business there was then followed, and was soon completed. The English Fruit and Rose Company, Hereford, sent a seedling Apple, *Cranston's Pippin*, supposed to be the result of a cross between the Sturmer and Ribston Pippins. Fruit medium sized, oblate, slightly angular, heavily covered with russet, especially on the upper side, lower side clear; stalk thin, half an inch long, deeply inserted; eye partly open, set in a shallow, puckered cavity; flesh greenish yellow, tender, sweet, and with some of the flavour of Sturmer, but intensified. Some Apples look better than they are, this is better than it looks. An award of merit was unanimously awarded.

THE VEITCHIAN PRIZES.—The prizes for quality in dessert Apples and Pears were awarded as follows:—Two dishes of Apples.—First, Col. Brymer (gardener, Mr. Powell), with Allen's Everlasting. Second, C. J. Massey, Esq. (gardener, Mr. J. Day), with Adam's Pearmain. Two dishes of Pears.—First prize withheld. Second, Mr. W. H. Divers, The Gardens, Belvoir Castle Gardens, with Marie Guise.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. H. B. May, R. Dean, H. Herbst, G. Stevens, J. Jennings, J. Hudson, C. Jeffries, G. Nicholson, J. Fraser, J. D. Pawle, W. Bain, T. Peed, C. E. Pearson, C. E. Shea, H. J. Jones, E. Mawley, H. J.

Cutbush, E. Beckett, D. B. Crane, T. W. Sanders, C. Blick, H. Turner, G. Paul, O. Thomas, and J. Walker.

Mr. H. B. May, Upper Edmonton, exhibited a charming group of Crimson Rambler Roses, Clematis, and Ferns. New Camellias from Messrs. W. Paul & Son, Waltham Cross, were very beautiful. Amongst the varieties were The Duchess, Duchess of Teck, Duchess of York, and others. Roses also came from this source. Messrs. J. Peed & Sons, Norwood, staged healthily grown foliage and flowering plants, comprising Clivias, Azaleas, Dracenas, Ferns, Palms, Boronias, and others. Messrs. R. & G. Cutbush, Southgate, staged a showy collection of Dutch Tulips.

Alpine plants in variety were exhibited by Messrs. Paul & Son, Old Nurseries, Cheshunt. There were Primulas, Adonis, Anemones, Hepaticas, Megaseas, Irises, Violets, and a hybrid Rhododendron named Duke of York. Messrs. W. Gordon & Sons, Murrayfield, Edinburgh, sent a basket of Alpines. Mr. Kelf, gardener to Mrs. Abbot, South Villa, Regent's Park, sent a fine collection of Hyacinths, Narcissi and Daffodils. Messrs. Barr & Sons, Covent Garden, exhibited Narcissi in their usual style. Most noticeable were Mrs. H. J. Elwes, Queen Bess, Santa Maria, Sir Watkin, Grand Duchess, tortuosus, Empress, Horsfieldi, Henry Irving, Duchess of Wellington, Goblin, Golden Spur and Emperor.

Mr. W. Howe, gardener to H. Tate, Esq., Streatham, arranged a diversified collection of bulbous plants, in which Narcissi preponderated. The Church Road Nursery Co., Hanwell, sent Cyclamens, and Mr. G. Mount, Canterbury, superb cut Roses. The colours were very rich and clear. Mr. W. Fyfe, gardener to Lord Wantage, Lockinge, Wantage, sent Fortune's Yellow Roses, and Camellia reticulata. Messrs. J. Veitch and Sons, Ltd., Chelsea, exhibited blue Primroses and Calla Elliottiana. The Amaryllis sent by Messrs. R. P. Ker & Sons, Aigburth Nursery, Liverpool, were very good and well diversified. Winter-flowering Begonias from Messrs. H. Cannell & Sons, Swanley, were showy.

Miscellaneous foliage and flowering plants from Messrs. J. Laing and Sons, Forest Hill, were finely shown. There were Clivias, Dendrobiums, Cattleyas, Acacia Riceana, Azaleas, Boronias, Croton, Palms, Ferns, and others. Messrs. Cutbush & Sons, Highbate, staged a superb collection of Hyacinths, besides Tulips and other plants.

ORCHID COMMITTEE.—Present: S. Courtauld, Esq. (in the chair); with Messrs. J. O'Brien, De B. Crawshay, N. C. Cookson, G. W. L. Schofield, W. H. White, W. H. Young, H. J. Chapman, Thos. Chapman, T. Statter, W. Thompson, W. H. Protheroe, H. Williams, F. Mason, J. Douglas, H. Ballantine, H. M. Pollett, E. Hill, J. G. Fowler, and T. B. Haywood.

Messrs. Linden, Brussels, exhibited a collection of Odontoglossums, amongst which were some beautiful varieties. Messrs. F. Sander and Co., St. Albans, staged Cattleyas, Odontoglossums, Dendrobiums, Cypripediums, and others. Mr. S. Cooke, gardener to De Barri Crawshay, Esq., Sevenoaks, sent half a dozen Odontoglossums; Mr. W. S. Burnell, gardener to W. Ellis, Esq., Dorking, also sending Odontoglossums in good variety. Mr. W. A. White, gardener to Sir Trevor Lawrence, Bart., Dorking, sent miscellaneous Orchids of considerable beauty and interest. Mr. Whiffen, gardener to J. Bradshaw, Esq., Southgate, staged a small collection of Orchids; as did Mr. Guyett, gardener to J. Gabriel, Esq., Streatham.

Orchids were beautifully shown by Messrs J. Veitch & Sons (Ltd.), Chelsea. Quality and quantity were alike conspicuous. Odontoglossums, Cattleyas, Cypripediums, Dendrobiums, and others were represented. Mr. Ballantine, gardener to Baron Schröder, The Dell, Egham, sent a few Odontoglossums of great beauty. There were only a very few plants, but they were of the finest quality.

AWARDS.—Floral Committee.—Silver-gilt Flora medals to Messrs. R. P. Ker & Sons, Hippeastrums, and Messrs. Cutbush & Sons, bulbous plants. Silver Flora to Messrs. G. Mount, cut Roses; H. B. May, Roses and Clematis; J. Laing & Sons, miscellaneous plants; G. Kelf, bulbous plants, and the Church Road Nursery Co., Cyclamens. Silver Banksian to Messrs. J. Peed & Sons, miscellaneous plants; Mr. Howe, bulbous plants; Paul & Son, alpines; H. Cannell & Sons, Begonias; and W. Paul & Son, Camellias and Roses. Bronze Banksian to Messrs. W. Fyfe, Camellias and Roses; and Cutbush & Sons, Tulips. Orchid Committee.—Silver-gilt Flora medal to Mr. W. C. Cookson, Phaius Cooksoni; silver Flora to Messrs. J. Veitch & Sons, Limited, W. H. White, and H. Ballantine. Silver Banksian to Messrs. J. Bradshaw, W. S. Ellis, T. Gabriel, L. Linden, F. Sander & Co., and De Barri Crawshay.

CERTIFICATES AND AWARDS OF MERIT.

Amaryllis Pera (J. Veitch & Sons, Ltd.).—A handsome brick red variety with white markings (award of merit).

Anthurium Scherzerianum Géant Sanglant (L. Linden).—A very fine variety of the type (award of merit).

Disporum Leschenaultianum variegatum (J. Veitch & Sons, Ltd.).—An effective foliage plant. The colour is green margined and striped white (award of merit).

Erythronium Nuttallianum (R. Wallace and Co. and Barr & Sons).—A beautiful pure yellow variety of *E. grandiflorum* (award of merit).

Narcissus Ellen Wilmott (Rev. G. H. Engleheart).—A bicolor of the first quality. It has the substance of Empress, but is earlier than any other of the section (first-class certificate).

Narcissus Lettice Harmer (Rev. G. H. Engleheart).—This, too, is a bicolor of merit, with a beautiful trumpet, though not quite equal to Ellen Wilmott (award of merit).

Narcissus Southern Star (Rev. G. H. Engleheart).—Belonging to the small cupped section this is superb. The cup is of peculiarly rich orange red (first-class certificate).

Odontoglossum crispum Luciani (L. Linden).—The chocolate markings of this crispum are very handsome. The ground colour is white tinged with rose (first-class certificate).

Odontoglossum Ruckerianum ocellatum (W. Stevens).—The ground colour of this handsome variety is purplish rose in the sepals and petals and white in the lip. The spots of each are chocolate (award of merit).

Polyanthus Woodside Gem (R. Dean).—A gold-laced variety of excellent quality (award of merit).

Rose Antoine Rivoire (C. Turner).—A Hybrid Tea; the colour is cream, suffused with salmon (award of merit).

Tulipa Kaufmanniana (Barr & Sons and R. Wallace & Co.).—This is a very handsome Tulip. The colour is pale lemon, with a yellow centre. On the reverse of each outer petal is a large patch of red (first-class certificate).

ALLEGED "LAXITY" AT THE WESTMINSTER DRILL HALL.

WITH your permission, I should like to publish a matter which has just come under my notice. At the meeting of the Royal Horticultural Society, held at the Drill Hall, Westminster, on March 9th a gentleman known to me, and who is a most successful enthusiast in Violet culture, sent a sport to go before the Floral Committee. The plants were lifted, placed in a box, and sent off on Monday, the 8th, addressed to the Secretary, who did not acknowledge receiving them. Not hearing any more about them, a telegram was sent to Mr. S. T. Wright, asking him to send the plants back, who in return wired that the Violet proved to be Lady Hume Campbell. A letter followed the telegram to the same effect, and also contained an expression of regret that the plants were untraceable.

I should like to ask you who is responsible for the safe return of exhibits to their owners? If these plants are untraceable it naturally leads to uncomfortable feelings. Blooms from them had been sent previously to specialists, who recommended sending them to the Drill Hall. I hope soon to hear that the plants have been found, and by whom they were taken, and trust such laxity will not occur again on the part of those who are held responsible for the return of the exhibits, or the result will be that provincial growers will not care to send exhibits.

I have noticed there is no mention of the Violets in the reports, either in the "Journal" or "Magazine," which in my opinion makes it look worse, as all the other exhibits are given.—H. PROSSER.

[In reference to the last paragraph it is right to say that it would be practically impossible for any of the gardening papers to mention even half the plants that are sent to the Drill Hall meetings. As a rule only those which are honoured, or appear specially noticeable, are mentioned in the reports of the meetings. We do not know whether the Society is bold enough to make itself responsible for the safe return of exhibits. A clause is inserted in most schedules to the effect that while the officials will take all reasonable care they cannot hold themselves responsible for injury to or loss of exhibits. We have observed that Mr. S. T. Wright is most watchful during the meetings, but seeing the crowded tables from end to end of the Hall it would obviously be a simple impossibility for him to have his eyes, however sharp, everywhere at once, and thus prevent mistakes of the nature indicated occurring. It is very regrettable when they do occur, as also is in a less degree the moving of new plants from their positions before the appointed time except by the Society's officials; for instance, artists taking plants away for sketching, and thus denying to other artists an equal opportunity for sketching them, to which it seems to us they are justly entitled.]

ROYAL HORTICULTURAL SOCIETY'S COMMITTEES' AWARDS.

YOUR correspondent "A. D.'s" latest contribution scarcely shows much advance over his previous effort either in logic or consistency, but it must be admitted that he has developed a marvellous capacity for "straining at a gnat and swallowing a camel." He is keen to discern how "diverse the conditions" between the Temple and the York and Chester Shows, but is, apparently, not yet awake to the equal diversity between the latter and a Chiswick or ordinary Drill Hall meeting, a recognition of which tumbles his original criticism about his ears. "That is enough on that point," as your correspondent remarks.

But even when we leave it, and get to another point, Mr. "A. D.'s" longings are not very much clearer. In his original letter (p. 162) he "fears" that there is not "the slightest probability that any checks will be put on the present perhaps too free granting of awards," and has "long contended that in many directions it is now time that higher standards of excellence were set up." And then the Council of the R. H. S. falls under the critic's displeasure, and he "cannot see, without the Council take action and formulate some definite rule, how any reform can be effected."

Quite clear so far, but now this craving for "reform" and "definite rule" seems to have passed away. At any rate Mr. "A. D." (p. 212) now assures us "I do not think the present too free making of awards should be restricted in the least." This is a fairly startling anticlimax, surely, especially after his censure of the Council for not having formulated a rule to restrict it.

When a man frankly admits that the granting of awards has been "too free," and demands "reform" and "definite rule" to enforce it, one is scarcely prepared to be told that he is quite contented with things as they are, and that even if the granting of awards have been "too free" he has not the slightest wish that they should be "restricted in the least."

But, without labouring further to ascertain what may be your correspondent's very latest views upon the point, we may thank him for having (when in his earlier frame of mind) called attention to a matter which seriously affects the value of the Society's awards; and it is to be hoped that the Council will take Mr. "A. D.'s" (original) injunctions to heart, and formulate, for next year's guidance of its Committees, a practical regulation aimed at a reform which has become very necessary.—F. R. H. S.

DO PLANTS "THINK?"

ALTHOUGH I have not seen a bunch of Grapes spring from the "old stem of a Vine without any leaf whatsoever," as described by your facile correspondent "The Scribe" on page 206, I have seen bunches issue direct from the buds of canes for the time of bearing Grapes, which admits of a similar explanation to that given by "A Gardener." The Vine was so "full of fruit inside" that it sent out a bunch without leaves. This is a very important point, and indicates that fertility depends on the high elaboration of the juices and storing of assimilated matter. That the Drumlanrig Vines, under Mr. D. Thomson's charge for so many years, are "so full of fruit inside" as to push a bunch of Grapes from the stem of one beneath the stage is not matter for wonder, for the whole practice of the veteran has been to get the stores of the soil into his cultured subjects, and thus bring out a maximum of useful produce of superior excellence.

Whether "The Scribe" is not writing without book in stating that "the tendril of a Vine is a changed or modified leaf," does not appear "plain and easy." Of the tendril being ennobled into a bunch of Grapes whilst embryonic by the assimilated matter "full of fruit inside" the Vine there is no question, and good service has been done by introducing the "plain, good, working gardener" into the subject. Many such gardeners achieve great results without knowing exactly the "reason why."

But the bunch of Grapes is not unique in springing from the old stem "without any leaf whatsoever," for other plants with tendrils act similarly, and some that do not have tendrils also push flowers from the old stems. Passifloras do, especially *P. racemosa*, syn. *P. princeps*, not occasionally, but annually, and sometimes two and three times a year. I had one some thirteen years with 3 feet of old stem below a stone shelf of that width, which gave not one, but many racemes of scarlet flowers. Some of the racemes were 3 feet in length. The buds actually formed in the old stem, and every one produced nothing but flowers or bracts. In this case the whole leaves and tendrils were transformed in the bud, and this itself formed of the material "inside"—the elaborated and stored matter essential to fertility. But the raceme is not a transformed tendril, as in the case of the bunch of Grapes, for no Passiflora tendril undergoes such "metamorphosis," and thus an opportunity offers for explaining the "reason why" the tendrils, as well as the leaves, disappear as parts no longer useful.

The Aristolochias also push their curious flowers from old stems in some cases, leaves being dispensed with, there not being any tendrils in this instance to transform. Numerous other instances might be cited of the higher plants at times dispensing with leaves under certain conditions, but it proves nothing of cultural consequence, as the power to so act has been derived by the presence of them concurrently or at a prior stage. The plants, as the "gardener" has it, are "so full of fruit inside" that it must come out somewhere.

As for Vines or plants having the power to "think" there may be such thing. I will say that some of them act as if they had, for many of them possess much sense, both in phænogamous and cryptogamous, especially in "smelling out" their food and utilising it to the best advantage, which is not always the case with the highest creature assuming the prerogative of thinking. What has more of "think" in them than the lowest members of the vegetable world—the Myxomycetes?

Take, for instance, the clubbing, finger-and-toe fungus, *Plasmodiophora brassicae*, the plasmodium of which creeps about in search of its essential Cruciferae. Get hold of a plant of this lowly organism, and place it on a piece of glass in rain water, just a thin film sufficient to allow it to creep about. Place it under the microscope, and then see how quiescent it is in the dry air of an empty room, where no smell of cruciferous plant comes. Leave it there, and fetch a little Cabbage-stalk or Turnip-root pulp, place on the glass away from the plasmodium, then look, see the plant wake up, stream out in the direction of the pulp, and creeping, like a snail, even leaving a trail behind, behold it pass to the pulp, and at once work as "flowers of tan" on a bark bed. Whilst active sprinkle a little lime around, but not so as to touch the plasmodium, then see the amœba-like plant shrink into a ball, a dead-like body, and strive to surround itself by a wall for protection, forming, if it can, several cells, each containing a little of the naked protoplasm.

"Think" is not the word for such action, but sound, practical, useful "sense." Pursue the matter further, and afford a plasmodium of the fungus named opportunity of choice by placing it in the centre of a piece of glass in a thin film of moisture, also equidistant from it pulp of Turnip on one side and chalk on the other. Now note the plasmodium

make for the Turnip pulp and run away from the chalk. Thus the lowly Plasmodiophora "smells out" its food.

Finally give a Plasmodiophora brassicae plasmodium no choice, but place before it a dish of air-slaked chalk lime, and note how quiescent it becomes; then watch the lime diffuse in the film of moisture till it embraces the plasmodium, and observe how the organism gets "smaller by degrees and beautifully less," nothing at last remaining but a dark stain—organic matter resolved into inorganic—the essential food of chlorophyll-possessing plants.

Now "think," and, taking a lesson from the *sense* of the plant, act in favour of the crop by applying a dressing of lime to land on which Cabbages club and Turnips finger-and-toe, using sufficient to bring that in the soil up to 2 per cent., apply at the rate of 10 tons per acre, 1½ cwt. per rod, of best chalk or land lime freshly burned, placing in little heaps convenient for spreading, covering with a little damp soil till fallen, then spread evenly, leaving for a few days, and then ploughing in, which being about 5 inches deep amounts to about 2 per cent. of lime, therefore in digging-in lime do not place it deeper. Choose a dry time for operating, July being a proper time if Turnips or Brassicas are taken after Potatoes or other early crops, or in the spring, say March, for summer crops, always with ground in good working order.

Mr. Thomson's practice with the Vines, and getting them full of "fruit inside," is that of affording them a healthy rooting medium, supplying suitable nutrient elements and proper moisture, allowing ample foliage, kept clean and exposed to light and air for the elaborating and storing of nutrient substances in the Vines—to wit, Grapes in embryo; then they are sure to come out where wanted, with an occasional freak sufficiently strange to cause people to "think," as clearly plants do in their way, if there be any meaning in their ways. Even roots run after sweet wholesome food, and will not go where soddenness and sourness prevail if choice be given. In culture the plants have often only "Hobson's choice," the thinking on their part being precluded, and in many cases there are no Grapes on the stem, because there are not any "inside" the Vines to come out, or perhaps only a few for shanking, if before that they do not twist and twirl in any direction other than of bunches. The "metamorphosis" rests with the cultivator, some Vines having so much "inside" that they will even turn incipient tendrils on laterals into bunches, that often give Grapes of excellent colour and bloom.

What a plain gardener would term the following I do not know; but there is *sense* in it, and a confirmed habit, no mere freak of Nature. The antherozoids of Ferns are small slender bodies, coiled up in two or three turns and provided with a tuft of fine hairs at one end. They are the male organs in matter of fertilisation and contained in cells, which in water or on a film of it on soil, absorb moisture, swell, and burst, thus liberating the antherozoids, which move actively about in water, and then always manage to reach the archegonia or female organs, and effect fertilisation. That is Nature. Decidedly; but let us take a few of these antherozoids, and give them choice of something sweet—say, a weak solution of sugar and something acid, such as diluted vinegar. Place the antherozoids equidistant between the two solutions, letting them have water to move about in, and if they make for that consisting of sugar and water, leaving the vinegar and water severely alone, what is that but *sense* in choosing the sweet and refusing the sour? Oh, it is Nature! Why, everything is; and it works by undeviating law, so that "think" has no place therein, but all is matter of fact. Nothing else is evidence.

Plants have a certain power of selection in matter of food, and we like to make them harmonise with our views; but there is no analogy whatever between these and those of plants, those resemblances frequently advanced having no existence but in the imagination, and belong only to the creature of all the intellects, whose "think" often reaches the vanishing point when brought face to face with the stubborn realities of disease; then real fact alone is of any service, and the more of it the better.

Inherent tendencies, such as plants twining round sticks in accordance with the sun, others doing the exact contrary; some plants growing from gloom into light, others fleeing from sun into shade, together with such variations of forms and adaptation to circumstances so that no part of the earth's surface is without some form of vegetation, are wonderful things to "think" about, but whose knoweth anything for certain about any of these forms of life has attained unto a good thing, the "reason why." Then all is "plain and easy," and needs no "metamorphosis" any more than a parasitic fungus of an endophytic nature requires leaves or roots, but dispenses with such means as absolute hindrances and of utter inutility to its mode of life.

—G. ABBEY.

[Well done, Mr. Ahbey; nothing is too great or too small for him; but does he know that those wonderful organisms, Myxomycetes, are not as much animals as plants in the "creeping-like-a-snail" stage? This, however, does not affect the general question of the sentiency of plants.]

CHRYSANTHEMUM AND STRELITZIA.—I have enclosed a bloom of Chrysanthemum Mrs. E. W. Clarke, which I think is good for so late in the season. Also a flower of Strelitzia, which is not, so far as my experience goes, found in many gardens. — E. R. WEBBER, St. Catharine's, Worcester. [The Chrysanthemum is undoubtedly good for the time of the year, though other flowers are now so abundant that autumn beauties are scarcely wanted. The Strelitzia is curiously beautiful, and might be more grown for adding the desirable diversity.]

YOUNG GARDENERS' EXAMINATIONS.

VINES—SETTING AND THINNING.

ACTING upon the Editor's suggestion in the Journal of February 12th I enclose sketches of unthinned, also of properly and improperly thinned bunches of Grapes. In each case the drawing was made from a Black Hamburg Vine. To enable the flowers of the Vine to set it is necessary that the "cap" which covers the stamens be removed to allow the pollen to disperse. Shaking the Vines every day when they are in flower materially helps to achieve this object. In the case of shy-setting varieties the hand may be drawn lightly down each bunch. A dry, warm, and buoyant atmosphere is very essential at this period.

As soon as the berries are set all superfluous bunches ought to be cut off. Do not leave more than one bunch on a shoot. The quantity of Grapes to be left on the Vine should be regulated by the amount of healthy foliage it has. When the berries are almost the size of peas they are ready for thinning. A small forked stick is useful for holding the bunches, to avoid touching them with the hands. Be careful also not to rub the neighbouring bunches with the head or arms, as this often causes them to rust. The shape of the bunch varies in different kinds of

FIG. 56.—UNTHINNED BUNCH.

Grapes, and when thinning this should be considered. Some have large drooping shoulders, which require tying up lightly with matting. First dislodge all remains of the stamens, by tapping gently with the Grape scissors on the stick employed to hold the bunch; then remove the seedless berries, and those situated near and turning in towards the main stalk. The remaining berries may afterwards be thinned, so as to allow each one room for its proper development.—H. H.

[Sketches very creditable. It will be seen in the well thinned bunch that berries are left on the upper side of the shoulders, so that in swelling they will be pressed back to the stem, as they should be. The berries are also uniform in size. In neither respect is it the same with the improperly thinned example, while in this the workmanship is obviously inferior.]

TUBEROUS BEGONIAS.

It is now time to see about starting these most useful summer flowering plants which look so charming in our conservatories during the summer months.

Begonias are of easy culture, and can be produced from seed and by cuttings, tubers forming either way, and they will retain their vitality for several years if they are stored away in a warm cellar or a frost-proof shed.

The tubers should now be taken from their storing place (if not already done), and placed in shallow boxes, covering the bottom of the boxes with leaf mould, then placing the tubers on it, and partly burying them with more leaf mould. After this has been done they may be placed on a shelf near the glass in a cool house where ventilation is afforded daily in mild weather. If the leaf mould is fairly

moist they will soon make a move both in leaf and root action. After they have got a fairly good hold in the leaf mould they should be potted, and if they are wanted to be increased the tubers may be cut in two or more pieces, depending on their size.

The pots first used should be just sufficient to take the tubers so as to allow for larger pots eventually, the most useful size for flowering in being 6 and 8-inch. The plants should still remain on the shelf in the same house until the weather permits them to be removed to a cold frame, where they should be freely ventilated and shaded from the sun in hot weather.

They ought not to be allowed to flower until they are in their final pots, and all the buds should be picked out until the plants are well established in them; then remove them to the conservatory, where for the next few weeks they will be one of the chief features, arranged in a bank of Maidenhair Fern or other foliage plants, and frequently watered with weak soot water. As regards soil, I have always seen them do well in good fibrous loam and a little, but good, leaf mould with the addition of some coarse sand and old manure from a spent Mushroom bed. The pots should be clean and carefully crocked, as the watering of the Begonia must be carefully done, so as not to allow the soil to get sodden, as the roots are tender and apt to decay.

Ripening and storing the tubers, or commonly called drying them off, is one of the chief points in Begonia culture. As soon as they have finished flowering and the leaves begin to change colour and look shabby the plants should be removed from the conservatory to another house where ventilation is provided more freely, and there gradually dried off. They may be stored in a fairly warm cellar or under a greenhouse stage where the frost and water from the plants above cannot reach them. Care must be taken not to place them near the hot-water pipes or flues. Although stored away in their resting place they should not be forgotten, as if there are any mice about it is surprising what damage they will do in a couple of nights to the tubers.—W. LOCK.

DRACENAS.

In dealing with the propagation and culture of Dracenas, I will divide the subject into two groups—first, the large-leaved strong-growing varieties; and second, the narrow-leaved delicate varieties, commencing with the former. To obtain large plants in 9 and 10-inch pots, cuttings should be placed in a shallow pan or box about the end of July. I find those taken from the roots of old plants succeed the best. The roots should be cut in lengths of about half an inch, and inserted in a compost of one part leaf mould and one part silver sand. Place in

FIG. 57.—IMPROPERLY THINNED BUNCH.

the propagating box, and keep them close until small shoots appear above the soil, when they may be lightly syringed, and given a little air on bright days.

About the end of August we should have plants ready for placing in 3-inch pots, using a compost of one part good loam (not too rough), and half a part each of peat dust and silver sand; place in a propagating box, keep the plants well syringed, then little or no water will be required

at the roots. About the end of September the pots will be fairly filled with roots, when they may be taken out of the propagating box and placed on a shelf near the glass in a temperature of from 65° to 70°, never falling below 60°. They must be carefully watered through the winter or the roots will suffer.

Transfer the plants to 5-inch pots about the middle of January in a

FIG. 58.—PROPERLY THINNED BUNCH.

compost of two parts loam and one of peat, with a good sprinkling of silver sand and fine bones. Apply water very carefully; syringing may be sufficient until the plants begin to grow. As soon as the roots touch the sides of the pots give another shift into 7-inch pots in the same compost as before, with the addition of a little artificial manure, such as Clay's or Thomson's. The plants must now be shaded from bright sunshine and kept well syringed, also the floors of the stove well damped. About the beginning of July the plants will be growing vigorously, and may have their final shift into 9 and 10-inch pots, using a compost of two parts good loam, one part rough peat, half a part Mushroom bed refuse, half part silver sand and rough bones, with a sprinkling of artificial manure. Well drain the pots and pot firmly. The shading must be removed in September and plenty of air admitted through the day to get the plants well coloured and hardened before being taken to the house.

Some of the Dracenas for the above treatment are—Shepardi, Youngi, Mooreana, amabilis, Lindeni, Baptisti, H. K. Freake, Gladstonei, Victoria Regina, and australis. Large plants of these stand in the house for weeks, and some of them months, without much injury. They are extremely useful for dark recesses and corridors where flowering plants would be out of the question.

I will now deal with the narrow leaved varieties. These are more graceful than the former, and are better adapted for table plants and lighter forms of decoration. The cuttings should be inserted in shallow pans in January in sand and peat dust in equal proportions, this they seem to take root in very readily. Place in the propagating box, and when the plants are large enough to handle transfer to thumb-pots, using the same compost as for cuttings, place back in the propagating box, and keep syringed; no other watering will be required. When the thumb-pots are full of roots shift the plants into 3-inch pots, adding a little fibry loam to the compost, and keeping the plants in the propagating box until they commence to grow again, when they must be removed to a shelf near the glass, in the stove, and shaded from bright sunshine.

About the middle of June they will be ready for their final shift into 5 and 6-inch pots, using a compost of one part sound fibry loam, half a part of peat, with a good sprinkling of silver sand and artificial manure. A second batch of plants should be brought on later in the season, and established in 3-inch pots, these being very useful for table decoration. They are best grown in twos or fours of each variety. The tops may be taken from some of the older plants by mossing them,

but I think the cuttings grown right on without a check make the healthiest and most symmetrical plants.

Some of the best varieties for our purpose are Lord Wolsley, elegantissima, norwoodensis, Princess May, Duchess of Portland, ensifolia, and gracilis.

Dracenas are subject to the attacks of red spider, thrips, green fly, and mealy bug. The three former, however, may be kept down by the constant use of the syringe during the growing season. Sponging seems to be the best method for destroying mealy bug, using an approved insecticide solution. After the plants have attained a large size they should be kept clean by sponging. If syringed too much water lodges in the axils of the leaves, thereby causing them to drop off. The floors and stages may be kept moist with a fine-rosed can. I keep a diary, and enter all work carried out every day. I find it very useful to refer to for information.—LEARNER AND WORKER.

"SWEET VIOLETS."

THE wild wood Violet has formed the subject for many a stanza, and carries with it an air of sweet modesty unseen in any other member of the great family of wild flowers. The other day when walking in the woodland I was attracted by a delicious odour, powerful in the fresh morning air. It must be of Violets, though the season was unusually early, and after brushing away the covering of dry Oak leaves I found them—a large clump of tiny white flowers, modest and shrinking, as if "born to blush unseen," yet how pure, how sweet, carrying in their simple forms a charm which one might look for in vain in the most gorgeous of the Orchid tribe. A little further on was a similar clump of the wild blue variety, perhaps even more common. The situation might have been chosen by the most skilful gardener, as protection was ingeniously secured, and the covering of dead leaves had made it even more complete. Tiny leaves were just unfolding, and the earliest flowers were mounted on short footstalks. They seemed to have been in a hurry to open, in order to be the first to bring a message of gladness.

Let us turn to another section of the family—"Sweet Violets; penny a bunch." Turn down whichever street you will in the metropolis at the present time and this cry breaks on your ears, and bunches of Violets are poked in your face. Thousands of city clerks appear at the office every morning with a fresh bunch in their buttonholes. Watch them dotted round the theatres, the concert rooms, and every other place of amusement, and see the well-dressed city man stop to have a bunch pinned into his coat by the flower girl at the street corner. In the early morning Covent Garden Market seems pervaded with Violets. Wholesale dealers are busy selling, and retail vendors are equally anxious to buy. Box after box are opened, and no sooner opened than they are emptied and hurried off in this direction and in that to keep the cry and supply the demand for "Sweet Violets."

The Czar is the principal variety, and though the colour is deep and flowers of good size, there is a lack of the delicious odour which characterises the native of the woodland, or even the Czars which are now blooming so profusely in the garden. This is a pity, for when the Londoner buys his bunch of Violets one would like him to have with it its fulness of scent. Not being produced under their natural conditions, and in an atmosphere more genial than ours, we get the flowers in abundance, but little of their most pleasing attribute—the scent. Then there is the close packing, the long journey, and continual knocking about, which do not tend to improve the faint odour they have to begin with, and consequently the Londoner gets his Violets almost devoid of scent. The wily flower vendor knows this, and to supply the discrepancy he sometimes "fakes" them by dipping the flowers into a liquid scent of Violet odour, and then displays them "all sweet" to his customers.

So much for the imported Czar. But in our gardens we have no such fault to find, as the borders and beds where they grow are now delicious with them. Thanks to the mild winter we have been picking them for some weeks past. The Czar does well under the protection of a wall, and grown in such a position a few blooms can generally be picked through a mild winter. Even in a northern aspect so protected the plant does well, and produces abundance of flowers. Like its relative of the woodland, it revels in a rather moist position, a soil rather strong in character being the most suitable. The plant, however, is wonderfully accommodating, and there are numerous spots in many gardens that might be utilised, aye, and beautified by the introduction of this time-honoured member of the Violet family.

Those who aim still higher, and are content with nothing less than frame-grown Marie Louise, Neapolitan, and the white Comte de Brazza, have their wants supplied abundantly, for the recent warm sunshine and genial spring-like weather have caused the plants to flower profusely. These varieties, too, find their way into the market in increasing numbers, though the sale of them is principally confined to the florists' shops. Simple though the routine is, many people stumble over the cultivation of double Violets, generally through coddling the plants, a process to which they hold strong objections. It is during the growing period of the plants during the summer that the principal care is required, and various methods of propagation are adopted. Some growers split up the old plants in the early summer, and place the portions at once in their growing quarters. A better plan, however, is to make cuttings of the young side growths (not runners) in April, and root these in a frame over a slight hotbed. When thoroughly rooted they should be planted in rows on a warm border, previously forking in a dressing of thoroughly decayed Mushroom bed refuse. The after cultivation consists of keeping the hoe continually worked between the

rows, and pinching off all the runners as they appear. If the latter are allowed to remain they draw the nutriment from the parent, which is detrimental, as the aim should be to get plants as strong as possible for transferring to the frames in October. During periods of drought applications of water or liquid manure are highly beneficial.

Whether hotbeds are beneficial for Violets is a point that has been much discussed, and one on which opinion is divided. There are certain risks of the bed being too hot at planting time, and I have frequently seen plants produce abundance of bloom for a few weeks after transferring to the frames, owing to the forcing effect of the manure, and then the leaves have damped and withered, and the plants ceased entirely to throw up flowers. Such is not a desirable state of affairs, and perhaps there is no better method of growing Violets than close to the glass in an ordinary brick frame, round which runs one row of 2 or 3-inch pipes. These need not be heated, except in severe weather, and then only to keep out the frost.

Air is one of the great essentials to successful Violet culture under glass, and on all favourable occasions a free circulation should be afforded. Damping is often prevalent during severe weather, when the frames remain closed for any length of time. The earliest opportunity should always be taken of picking over the plants, and removing all leaves affected. If this is neglected the evil spreads, and wholesale loss is the result. At this time of the year and later care should be taken that the plants do not suffer through drought, and an occasional application of lukewarm liquid manure from the farmyard will increase and prolong the production of flowers. If the frames are required in a few weeks time for the raising of vegetables and so forth, and it becomes necessary to remove the Violets, those plants not required for propagation may be packed close together under the shade of a wall, and if supplied with water will continue the bloom for several weeks longer.

The once popular Neapolitan variety appears to be almost superseded by the deeper hued Marie Louise, which is also very sweet, and the white section is monopolised by the multi-flowering Comte Brazza. Several others there are, but the palm of popularity must be given to the above. Whether wild or cultivated, the early spring is the true season of the Violet. Year by year its popularity increases, and, unlike some flowers, its presence never seems to tire us. Take the Snowdrop, the Crocus, the Daffodil, or the Primrose; we welcome the first blooms with ardent admiration, but as the weeks roll on and the flowers are common we seem to take little notice of them. Not so the Violet; its charms are irresistible.—G. H. H.

SPRING SHOW AT EDGBASTON.

THE Birmingham Spring Exhibition, usually held in the Town Hall having been abandoned, it was a happy inspiration of Mr. Robert Sydenham to have a show on his own account by offering substantial prizes in classes of pot plants and cut flowers. A brilliant display resulted on the 18th and 19th ult. It may be remarked that the Show was appreciated all the more from the fact that no Daffodil and Narcissus show is to be held here this year owing to financial reasons. In addition to the exhibits of the competitors Mr. Sydenham contributed a splendid collection of such as Tulips, Hyacinths, Daffodils, and Narcissi in pots.

A group exhibited by the Rev. J. Jacobs, Whitechurch, Salop, in the class for a collection of Daffodils, not more than five of any one variety, was very beautiful. The best were Sir Watkin, Countess of Annesley, Obvallaris, Dean Herbert, Golden Spur, maximus, Emperor, Empress, P. R. Barr, Horsfieldi, Johnstoni, Queen of Spain, cyclamineus, W. P. Milner, Nelsoni major, Burbidgei, Barri conspicuus, Nelsoni major, poeticus poetarum, Grand Monarque, Cynosure, Jaune Supreme, Robin Hood, bulbocodium, and the sweet-scented single Jonquil. Mr. I. Cooke, Shrewsbury, was awarded the second prize for a good collection.

For twelve single Hyacinths, distinct, Mr. A. Cryer, gardener to J. A. Kenrick, Esq., Edgbaston, was awarded the first prize. Mr. Priest, gardener to A. W. Hulse, Esq., was second, and Mr. J. Price, gardener to Sir John Jaffray, third. For six pots Hyacinths the first prize was worthily awarded to Mr. W. A. Sarsons, Moseley, an amateur, for excellent examples not equalled by any other in the show; second to Mr. E. C. Fowke, and third to Mr. Snead, gardener to E. M. Sharp, Esq. For twelve pots of Tulips Mr. Priest ranked first, Mr. Isaac Cooke second, and Mr. A. Cryer third. For six pots ditto Mr. Snead was to the fore, Mr. C. Knight, Harborne, second, and Mr. B. Horton the third position.

For twelve pots of single Narcissi Mr. Priest took the lead, Mr. A. Cryer the second, and Mr. Isaac Cooke the third position. For six pots of Narcissi the first prize was awarded to Mr. Snead, the second to Mr. E. C. Fowke, and the third prize fell to Mrs. H. Mitchell. For six pots of Polyanthus Narcissus, not less than four varieties, Messrs. I. Cooke, A. Cryer, and Snead were the prizewinners.

For six pots of Lilies of the Valley Mr. A. Cryer, Mr. I. Cooke and Mrs. H. Mitchell stood in their order named. For six pots of Hoteia japonica Messrs. Priest and A. Cryer were awarded the first and second prizes. For six pots of Cinerarias Mr. A. Cryer was the only exhibitor, with very good specimens, and which secured the first prize.

For a group of spring flowers in pots arranged for effect in a space not exceeding 30 square feet there were three competitors. Mr. Isaac Cooke was awarded the first prize for a tasteful arrangement, Mr. Priest the second, and Mr. A. Cryer the third prizes. A special extra prize to the most successful exhibitor in classes 1, 3, 5, 7, 8, 9, 10 was accorded to Mr. A. Cryer. A special extra prize to the most successful exhibitor in classes 2, 4, 6, 7, 8, 9, 10, fell to Mr. Snead.

A fine collection of Cyclamen, containing several superb varieties, was shown by Mr. R. Sydenham, also a beautifully bloomed specimen *Dendrobium nobile*. Mr. A. Cryer staged an excellent collection of a dozen plants of *Hippeastrums* raised from seed of his own saving. The blooms were large, and of varied rich colours. A certificate of merit was accorded them. A certificate of merit was also awarded to Mr. Isaac House of Westbury-on-Trym for a collection of fine and sweetly scented Violets, said to be of Californian origin. Mr. R. Sydenham displayed a set of his popular "Rustic Table Decorations." A rich display of Orchids, Hyacinths, Tulips, and Cyclamen in the adjoining glass structures materially add to the delectation of the visitors.

HARDY FRUIT GARDEN.

Protecting Wall Trees.—The cold biting east winds of spring, which frequently follow and sometimes accompany bright sunny weather, are in some circumstances very trying to fruit trees in blossom. The early-flowering stone fruit trees on walls, Apricots, Peaches, and Nectarines, almost invariably need some protection so as to obviate injury to the reproductive organs of the flowers when the latter are fully open. The blossoms are then most susceptible to untoward influences, such as storms of rain and wind, which beat and cut them about, saturating the delicate parts with moisture.

A severe frost then following destroys their functions, rendering the setting of fruit impossible. The object of protecting is to avoid such disasters when bad weather is prevalent by timely covering the trees while still dry, endeavouring to keep them so during the continuance of unfavourable periods. Frosts or low temperatures have but little effect when the flowers are free from moisture.

Protecting material is occasionally employed with advantage on very sunny walls to retard the opening of the blossom, thereby causing the flowering period to be later, and probably at a more favourable time. In such cases the trees are screened from the warm sunshine and fully exposed when dull and cold. As soon, however, as the flowers open protection from wet and frost must be resorted to, with plenty of sun and light afforded at other times.

Moveable Protection.—The advantages of protecting material which can be drawn off or on one side are obvious. Copings projecting 18 inches from the wall may be affixed temporarily upon which to hang blinds or curtains of tiffany, canvas, or frigi domo. The front part of coping should carry an iron rod on which rings can be placed, these being attached to the protecting material. By this means the blinds are readily drawn over the trees when necessary, and as easily drawn off. Some provision must be made at the base for securing the blinds tightly. Similar iron rods to the others fixed to uprights about a foot from the ground are suitable. The material ought not to touch the trees, so that air can circulate about them freely.

Fixed Protection.—When protecting material is not daily removed, but remains over the trees continuously during the time they need such aid, it is termed fixed, or in a sense permanent. The character, however, of the material should be such that while affording protection it ought not to exclude light and air. This cannot be properly done by close-textured materials, but it may be effected by fish netting two or three times doubled laid over the trees. Such protection can remain until all danger from frost and cold winds is past.

Grafting Fruit Trees.—It will soon be necessary to carry out grafting operations where such is proposed to be done. Trees having large thick branches which it is intended to attach grafts to should have the limbs prepared by heading them down in readiness for working when the bark in the stocks lifts freely, showing that the sap is in motion.

Crown or Rind Grafting.—Preparation of Stocks.—This is the best method for attaching grafts to large branches. Those branches headed down early need to be freshly cut over immediately before commencing grafting. When the scions are ready for insertion cut a slit through the bark of stock longitudinally the same length as the prepared part of scion. Choose a smooth portion of bark for the incision.

Preparation of Scions.—Scions must be perfectly dormant. The best portions for forming grafts are obtained from the central parts of young shoots well ripened. The scions, when prepared, should be about 6 inches in length, and have three good buds on the parts left above the inserted portion. The lower part of scion is cut slantingly, making the cut quite clean and evenly. In order to facilitate the insertion of the scion firmly on the stock remove a small portion of wood at the top of the slanting cut, thus forming a shoulder which will rest on the stock, holding the graft exactly in position.

Uniting Stocks and Scions.—Carefully lift the bark of stocks with a smooth wedge-shaped instrument. This will admit the scions. Push each scion down until the shoulder portion rests on stock. It is important that the inner bark or alburnous tissue of both stock and scion exactly meet, on one side at least, but better if on both. The inner bark is the actively dividing tissue termed the cambium, where new growth is originated by cells receiving the sap on its returning course from the

leaves. Having fixed the scions on the above principle, proceed to secure them permanently safe by tying matting securely round them. Finish by covering the grafts, also top of stock, with clay or grafting wax. This is important to exclude air, and maintain moisture for assisting the complete union of the parts.

FRUIT FORCING.

Peaches and Nectarines.—Earliest Houses.—Careful attention to ventilation is necessary in cold sharp weather, as cold currents cripple the foliage and give a check to the fruit, often causing it to fall, therefore admit a little air early, and allow the temperature to rise somewhat higher than would ordinarily be permitted rather than give air to keep it down and in doing so cause an inrush of cold air. The advance must be from sun heat, turning off the artificial heat and closing early. Stoning will soon be completed in the most forward varieties, when the final thinning must be effected, and the border may be mulched with partially decayed manure 1 to 2 inches thick, and the night temperature may be raised to 65° to 70° in mild weather, 70° to 75° by day artificially, and 80° to 85° or 90° from sun heat. This will bring the fruit rapidly forward and insure its swelling to a good size, but it will not have the colour and quality of that given more time. Tie-in the shoots as they advance, regulating them so as not to be too crowded, as this lets more light to the fruit for colouring, and the wood becomes more solidified and better ripened for another year. Outside borders will only need sufficient protection in the way of a mulch against frost and snow, and inside borders must have due supplies of water or liquid manure. When close pinching of the laterals has to be practised to keep the growths in order there is danger of starting the base buds, and extension only increases the vigour, frequently resulting in the principal buds pushing laterals instead of forming fruit buds. Such trees must be marked for lifting at the proper time, and when a shoot becomes so gross as to push the whole of the buds it is best to cut such away altogether, as they have large sap-vessels, and may fall a prey to gum, interfering with the proper training of the trees.

Vines.—Earliest Forced in Pots.—The canes started last November, that were duly attended to in regard to heat, moisture, and other cultural requirements, also furnished with supplies of liquid manure and surface dressings of rich compost, have the Grapes swelled to a good size, and these are changing colour. The supplies of liquid manure should be lessened gradually, so as not to give a check, and the atmospheric moisture must be reduced, yet do not withhold it entirely; but allow a gentle circulation of air constantly, and damp the house in the morning and afternoon, as moisture is essential to the finishing of the Grapes, and does not inimically affect early crops. Maintain the temperature at 60° to 65° at night, 70° to 75° by day artificially, and between 75° and 85° through the day from sun heat, ventilating freely in fine weather.

Early Houses.—In the house started early in December the Grapes are rapidly advancing towards the colouring stage, and should be afforded a thorough supply of tepid liquid manure, mulching with a little partially decayed rather lumpy material, such as sweetened horse droppings, or stable manure, with the strawy portion shaken out, answers well after it has been properly sweetened. With the border in a proper state of moisture and the stimulus given the roots, little, if any, further moisture will be needed by the border until the Grapes are cut; but there must not be any deficiency, as it is important that the foliage be kept healthy. Continue damping the house at closing time until the Grapes are well advanced in colouring, after which reduce the moisture gradually, but provide a circulation of warm air by day and night. This is particularly necessary with Madresfield Court and other Grapes liable to crack, and where these are grown it may be wise to dispense with the dampings, covering the border with rather rough dry material, excluding water from the house after the Grapes show colour, but with a little ventilation constantly, and this increased early in the day, the border not being too wet, this very fine early Grape does not show much disposition to cracking in the berries.

Vines Started at the New Year.—When these come into flower they will need plenty of warm, rather dry air, with a temperature of 65° to 70° at night for Black Hamburgs and similar sorts, and 70° to 75° for Muscats. All shy setting varieties must have their flowers gently rubbed with a camel's-hair brush to rid the stigmas of the glutinous substance about the time the blossom is fully expanded, choosing a warm part of the day after the house has been freely ventilated. Varieties deficient in pollen may be supplied from that affording it freely. On no account allow the thinning to remain a day longer than is necessary to ascertain the best set bunches. Free-setting varieties, such as Black Hamburgh, may be thinned as soon as the berries are formed, but Muscats and other shy setters ought not to be thinned until the properly fertilised berries are taking the lead. No rule can be laid down for thinning, as the berries vary in size in different varieties, and even of Vines of the same variety. Healthy, strong Vines swell much finer berries than those not so vigorous, but space must be left that each berry will have room to swell without being wedged or crushed, yet the berries must be close enough to preserve the form of the bunch when placed upon the dish. When the Grapes have been thinned and are fairly swelling supply liquid manure in a tepid state, and mulch with about an inch depth of rather fresh, but sweetened, lumpy manure, keeping it damp by sprinkling daily, especially at closing time. Admit air early and liberally as the heat increases, seeking to secure short-jointed wood and thick leathery foliage. Close early, with plenty of atmospheric moisture, raising the heat from the sun to 85° to 90°, and allow the night temperature to fall to between 60° and 65°.

Watering, Feeding, and Mulching.—From the time the Vines are started until the fruit ripens they must not lack moisture at the roots. It is extremely difficult to state how often the borders must be watered through these being so variable in soil and dimensions, in depth, and in their formation. A narrow border will need watering twice as often as one double the width, and a border of loose materials will require much more water and frequently than one formed of firm retentive soil, consequently the cultivator must be guided by the state of the Vines in relation to their rooting area. The proper plan is to examine the border, and when water is needed give a thorough supply. Surface dressings of the approved advertised chemical manures, and supplies of liquid manure may be given. The borders having been dressed at the time the Vines were at rest, a dressing after the Grapes are set, repeated about the completion of the stoning process, will help considerably, the material as regards inside borders being at once washed in, or a good supply at those times of liquid manure, and when the fruit commences to colour will assure the berries swelling to a good size. In the case of Vines restricted to narrow borders higher feeding will be necessary, affording liquid manure whenever there is need of moisture. Supply a mulching a couple of inches thick of rather lumpy manure, the best being stable manure freed from the straw, but it must be sweetened before introducing to the house, otherwise too much ammonia vapour may arise and injure the Vines.

Late Vines.—Syringe those that have commenced growth two or three times a day, endeavouring to secure an even break by closing with a moist atmosphere of 75°. Employ fire heat as may be necessary to secure a minimum of 55°. Vigorous young Vines do not start regularly, therefore to prevent a rush of sap to the upper part of the canes they should be brought into a horizontal position until all the buds have started.

Late houses of Black Hamburgs may be allowed to start naturally next month, they advancing sufficiently by sun heat and a little artificial warmth on cold nights to set and have the Grapes thinned by early June, and the fruit mainly forwarded by sun heat ripen in late September, which suits them very well, for if ripened earlier they are liable to lose colour and quality by hanging, which is common to all black Grapes with thin skins; even Madresfield Court becomes quite red by November, yet none loses colour so badly as Hamburgs.

Young Vines.—Canes planted last year as such and cut back to the bottom of the rafter or trellis at the winter pruning must be encouraged by gentle fire heat, so as to allow time for their making and perfecting a good growth. The laterals must have their points pinched out at the first leaf up to a height of 6 feet of the current growths on the canes, which will cause the buds in the axils of the principal leaves of the canes to form fruit buds and become plump for next season's fruiting, but above that height may be allowed to grow more, so as to strengthen the rod.

THE BEE-KEEPER.

FLOWERS FOR BEES.

THE weather has been wet and boisterous for some time past. The temperature, too, has been lower than is usual at this season. Still flowers may be observed in all directions in country districts, not only on the sunny banks by the roadside, but in the sheltered woodlands. On the former the most prominent at present are the yellow Buttercup, Primroses, and the wild Violet. The latter will soon be carpeted with the Wood Anemone; already in the more sheltered spots the blooms are almost expanded.

The bees work more or less on all the above—in fact, at this early season they may be observed to be hard at work collecting from flowers which they ignore later in the season when flowers are more plentiful. Take the Violet for instance. Although they are somewhat plentiful in the majority of gardens in the country and bloom freely in the autumn, it is an unusual thing to see bees at work on the flowers. At the present moment during a spell of bright sunshine the bees are busy amongst the expanded blooms of a bed of Victoria Regina Violet within a few yards of where I am writing.

One of the best pollen-producing trees is the common Palm Willow, which grows freely in any situation, but, like all the Salix tribe, prefers plenty of moisture. They are not only ornamental at a season when the majority of deciduous trees are bare (not having yet put on their summer garb), but useful, owing to the great amount of pollen they produce. It is, however, many years since bees have been confined to their hives so much as they have throughout the past winter, as up to the present there have been but few days in which the bees were able to venture far from home, so have derived but little benefit from the flowers.

GARDEN FLOWERS.

Under this heading may be included some of the flowers mentioned above, for are not Primroses and Violets cultivated in the majority of gardens? and what a showy early flowering variety

is Harbinger Primrose, distributed by our old friend, the late Mr. R. Gilbert, of Burghley? A few square yards of a border planted with this variety near my bees have been a sheet of bloom for several weeks past, and should be grown by all, irrespective of bee-keepers, for its beauty. It has also the advantage of being perfectly hardy.

The Winter Aconite and Snowdrops are now over, but owing to reasons given above they have been of less benefit than usual to the bees. The Crocuses are nearly past; there has been plenty of bloom. The bees, however, worked but little on them. Scilla sibirica is fast opening its flowers, which will last for some time to come. How handsome masses of this bulb look when in flower if planted under trees in the grass. In fact, the majority of bulbs will grow and produce seed freely if planted on the grass and allowed to remain without being disturbed for several years. The common single Daffodil will soon be in full bloom. This is one of the most showy and inexpensive bulbs grown, and when once planted on the grass may be allowed to remain. Bees work freely on it; but it does not produce pollen so freely as some of the others mentioned.

Tulips treated in the same manner are growing well, but the more forward varieties will not be in bloom for several weeks yet. Many other bulbs might be mentioned; useful as well as ornamental, but the above are amongst the most common.

FERTILISATION OF FRUIT TREES.

The buds of many of the fruit trees are now very prominent, the excessive rainfall experienced causing them to swell and expand earlier than might have been expected. Some of the more forward of the Apricots on south walls are a mass of bloom, and being within easy reach of the apiary the bees will fertilise the flowers, and in doing so will obtain sufficient pollen for their daily requirements. The fertilisation of fruit trees must not be ignored by bee-keepers, and the benefits derived from bees should be constantly kept in mind. I believe it would be of great advantage to all hardy fruit growers if they kept bees in proportion to the extent of their fruit farms.

If no account were taken of the honey they would obtain, in fact make that a secondary consideration, the fruit grower would still be a great gainer by having better crops of fruit, and as is well known, if the bloom is properly fertilised there is a much better chance of the fruit coming to maturity than if the reverse is the case.—AN ENGLISH BEE KEEPER.

TO CORRESPONDENTS

* * All correspondence relating to editorial matters should be directed to "THE EDITOR." Letters addressed to members of the staff after remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return rejected communications.

Kangaroo Vine (W. W.).—This is the popular name of your window plant, botanically *Vitis antarctica*. It is of easy culture, but some of the leaves are prone to fall after a winter's sojourn in a room. If the roots are healthy the plant will improve now. Stand it outdoors now and then during a warm shower, cleanliness of the foliage being highly conducive to health.

Green Fly on Gooseberry Bushes (Ama'eur).—The bushes may be dusted whilst dormant and damp with mist, or after rain, with quicklime. This has a good effect on the eggs, cleanses the trees of lichen and moss, and does good to the soil. Upon the first appearance of the aphides the bushes may be syringed with quassia water, 1 lb. of chips to 3 gallons of water; let it stand twenty-four hours, and strain before use. Another plan is to use the following:—4 ozs. of quassia chips boiled a quarter of an hour in a gallon of water, adding 2 ozs. of soft-soap whilst hot, dissolving it thoroughly, and straining. Both the

preceding are best applied with a spraying nozzle, directing the spray upward, so as to reach the under side of the leaves. A cheaper yet efficacious plan is to syringe the bushes with clear lime water, made by placing 1 lb. of quicklime in a tub with 3 gallons of water, stirring well together, letting stand twenty-four hours, then pour off the clear water, leaving the sediment. Later in the season it is also a good plan to cut off the infested points of the shoots and burn them, thus clearing the bushes of many aphides.

Cœlogyne Unhealthy (G. H.).—The discoloration does not extend beyond the surface, and we should not anticipate any evil results if the plants were healthy; but that does not seem to be the case, as the pseudo-bulb is puny, the leaves small and not well developed. Perhaps the plants require repotting, and if you do this give them fresh good peat with plenty of drainage. If you can induce a more vigorous growth they will flower satisfactorily, but when in a semi-starved condition you cannot expect them to succeed.

Scale on Oleanders (W. V. B.).—Neriums are subject to this species of scale insect, and then follows black fungus. The insect is known to gardeners as the orange scale. To free the leaves of it they should be washed with a solution of softsoap at the rate of 6 ozs. to the gallon of water. The plant first of all should be syringed with water at a temperature of 140°, which is not too high if syringed on the plant; but if the latter be immersed the water must be at 120°, and the plant may be kept in the water half a minute. The leaves are to be washed on both sides with a sponge, pressing whilst washing them, so as to dislodge the insect and remove the black fungus. After the leaves have been washed on both sides they should be allowed to dry, and then the plants should be syringed with water at 140°, laying the pots on their sides so that the hot water may not wet the soil. The insects near the midribs may be dislodged by employing a pointed stick. A good washing with softsoap will generally keep the insects under, but repeated washings are necessary to keep plants subject to it clean.

Compost for Cypripediums and Dendrobium (Young Grower).—A suitable compost for Cypripediums insigne and barbatum would consist of equal parts good fibrous peat, fresh sphagnum, and loam fibre, with a liberal admixture of potsherds or charcoal. The drainage must be exceptionally good, as these plants require abundant supplies of water at the roots while growing, and even in the winter must not be dried off in the way pseudo-bulbous plants generally are. In potting be careful to cut away all decayed roots, and spread out those that are healthy, so that the compost runs evenly amongst them. Cypripediums should not be raised above the rims of the pots, but kept slightly below, as in potting ordinary plants. Dendrobium nobile thrives best in peat and sphagnum in about equal proportions, with a few nodules of charcoal added to insure aeration. Fill the pots two-thirds of their depth with crocks, over these put a thin layer of rough moss, then press the compost firmly about the roots, keeping the base of the bulbs an inch or so above the rim of the pot, finishing so that they just rest on the top of the compost.

The Lackey Moth (A. B. C.).—The following methods of prevention and remedies are recommended by Miss Ormerod:—"Some good may be done by looking for the rings of eggs on the shoots, cutting these off and destroying them; also by destroying any yellow silken cocoons that may be found about the trees; but these methods are tedious, and, though they are of use where just a few trees can be carefully tended, are of little service in orchard treatment. A far better way is to watch for the webs, and, as soon as they are seen, to carry out the old French method and cut the shoots through with a pair of nippers and destroy them. It is well for one person to cut and another to hold a pail below for the web and all the caterpillars (which on the first alarm would throw themselves down by their threads) to fall into. The pail should have a few inches depth of water in it, or mud thick enough to prevent the caterpillars from escaping. A less troublesome, but less complete method, is to shake the boughs, or strike them smartly, so as to make the caterpillars drop, and sweep those that dangle by their threads in the air down with the hand. These may be trampled on, or gas-lime, quicklime, or anything that will kill them may be thrown on them, but it should be done at once. As the moths harbour under leaves and long grass, a properly kept state of undergrowth in orchards, free from overwhelming weeds and rank herbage, is of service in preventing attack. Much more attention to this matter is needed relatively to keeping down Apple pests than is commonly supposed. The dark, damp, confined air of the neglected overcrowded orchard fosters all kinds of insect pests, and as no grass cut in such circumstances would dry it is often left for rough feeding, or an occasional "skirming" of what is too long to remain uncut, and thus "pests" have possession; whilst where the trees stand apart, as they should, there is sunshine and fresh air to cause ripened growth, and lighten up the dark nooks that insects hide in. The grass can be properly pastured and attended to, and also the small birds have fuller access to do their work as insect-clearers."

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, at being often difficult to separate them when the paper is damp. (J.)—*Spiræa astilboides*. (W. H.).—*Forsythia viridissima*. (W. W. C.).—*Narcissus minor*.

WIREWORM.

WE have had it in mind to write of this pest for some time, but somehow other subjects came to the fore, and the wireworm was left in its native obscurity. However, to-day in reading the "Agricultural Gazette" we find their ravages are referred to, and a remedy—an old remedy in a new form—suggested.

What, in the first instance, is a wireworm. The wireworm is the larva of a small beetle known as "skip jack," "snap," or "click beetle," from their habit of flying up in the air with a kind of snap or click. They pass through three stages of growth—larva, pupa, and complete insect; but there is with them one strong point of difference with regard to other sorts, in that they continue in the grub or wireworm state for many years. The pupal stage appears only to last about a fortnight or so.

The "click" beetles are about a quarter to half inch in length, with a pair of long horns and six legs. The wireworms are of a straw colour. They, too, have six legs, and by these six legs can

be easily distinguished from other worms, which are all furnished with many more of such appendages.

Miss Ormerod, who has been a close personal observer of the habits of insects, has little doubt but that the eggs are laid either just below the ground near the food plants, or among the leafage on the ground level. Wireworm is most injuriously active on light soils, chalk, gravelly soil, fen land, and the like. It is a matter of vital importance to the wireworm that it should be able easily to get through the soil in search of fresh food, so that we find as a general rule that strong clay lands are exempt from this pest.

We have been looking over some old statistics of damage done by wireworm, and we will just note a few instances for the sake of the unbelieving. On one farm of 1000 acres the occupier notes that in an average of seasons the loss on his corn crop would amount to £700. This is Hampshire; and he further adds that the losses on most Hampshire and Wiltshire farms is equal to the rent! This is owing in a great measure to Sainfoin being a leading crop, and Sainfoin is the home and nursery of the wireworm.

Another man from Derbyshire says 5 bushels an acre is what he estimates as his loss from this cause. From Canterbury: "The average amount of injury is about one-tenth of the crop." Dalkeith: The wireworms have not left half a crop. These crops mentioned are corn crops. It attacks the young Turnip, Swede, and Potato plants, exterminating, or nearly so, the two former, and making of the latter a grubby sample. To the Hop grower it is an enemy to be fought against, and only exterminated by great cost. The wireworm is always to be found after such crops as Clover and old Grass. These crops are usually allowed to stand several years, then when broken up and sown, whatever the crop may be, the farmer is sure at least of one thing, and that is the presence of the wireworm in great numbers. "Dirty" land, too, encourages the growth of the pest—the cover is there, and advantage is taken of it.

Grass or Clover which is to be broken up for a crop should be fed down as closely as possible; then, say many experts, dress well with lime or salt, or both. Nothing consolidates land like the treading by sheep, and they are also close feeders. After ploughing, the land should be well rolled with what is called a Cambridge or ring roller. Where the turf has previously been pared and burned the danger of wireworm is reduced to a minimum, but this process is one that entails more expense than the ordinary farmer can stand.

Four, and even 6 tons of lime per acre are recommended, and even in one case 15 tons of gas lime per acre, but this seems to us very much in excess. No corn crop could stand this, and it is doubtful how the Turnips would like it the following summer. In a case where the farmer suspects the presence of wireworm to any extent (that is in old Clover ley or old grass), the safest crop to take, and a profitable one, is a Potato crop, especially a strong-growing variety. The plant is so vigorous that it gets clean away from any harm, then a crop of Wheat may be sown with confidence, and a good return expected.

In all and every case he must insist on generous cultivation. A strong healthy plant well forced on by suitable manures soon gets beyond fear of damage, while a poorly nourished plant must of necessity succumb. Firm ground and a healthy flourishing plant will bid defiance to the wireworm. Farmyard manure, by opening and lightening the land, will seriously encourage wireworm. Artificial manures are free from this defect.

It is also advocated that a crop of White Mustard grown and then ploughed in is a certain remedy; at any rate, it makes a capital manure. As a crop, too, Flax is safe from injury, and is being grown with success in some parts of the kingdom. It is an old remedy to sow Rape cake dust with the grain; the worm prefers the cake, and thus allows the young plant to get well ahead. Miss Ormerod has been trying some experiments, feeding worms with two different kinds of cake—viz., Indian Rape cake and Black Sea Rape cake. The Indian cake is made from

Mustard seed. Worms fed entirely on this cake died at the fortnight's end. She found those fed on Black Sea cake, or true Rape, were alive at the end of three weeks. She exposes a common fallacy that the worms burst from over-feeding. She found no one instance of this.

Now for this week's writer to the "Agricultural Gazette." He says, "Remembering the old custom of ploughing in a crop of Mustard as a protection for Wheat, I have had all my garden crops dressed with Mustard dross, a cheap form of Mustard refuse. This dross kills the wireworm in a few minutes." He goes on to add that this dross is pressed into cakes and exported to Belgium, to be ploughed into the ground where wireworm abounds. The cost is about 2s. to 4s. per cwt. He adds, that when farming in Northampton and Hereford 400 acres of land his annual loss from wireworm averaged £50 per annum.

This statement about the effect of true Mustard seems to fully bear out the facts in Miss Ormerod's experiments.

WORK ON THE HOME FARM.

We have again to chronicle a week of disappointment. No sooner have a couple of fine breezy days dried the land surface and the horses are yoked in the drill than down comes the rain again, and we are just where we were before. As we write it is too wet to cart muck, and as for the drag or the plough, they are much better in the shed than on the land in its present state. We have to-day met one of the largest arable land farmers in Lincolnshire; he says he has quite given up sowing for the present, and shall wait for drier conditions, even if he has to drill his corn late. Meanwhile he has been ploughing Wheat up, and says that much in his district is too thin to give any real prospect of an average crop. He attributes the loss of plant to the seed having been too bold, and having burst in the soddened soil; in his own words, "No more fat seed Wheat for me."

We hear many complaints of loss of plant from wireworm. Unfortunately rolling, the best remedy, has been hardly possible lately.

Lambing has proceeded more rapidly, and the yard at night is presenting a thinned appearance. Lambs are plentiful, but there is loss amongst the ewes; several cases of liver fluke have been noted, and these on farms not usually liable to this disease. We suppose the disease has been encouraged by the abnormally wet autumn.

The wet has been bad for the young lambs, still they are better out than in the pens. It is bad for the ewe to keep her stewed up in a close place. Care should always be taken that the ewes should not have access to water, as if a sheep is in the least feverish, and gets as much water as she cares to drink, she will almost certainly die.

It is time the cattle were getting a little hardening by being turned out for a few hours every day. If the pastures are handy to the yards they would be better out altogether during the day, and most farmers will be glad to have them out, bedding is so scarce. With shelter to fly to in a storm and careful shepherding there is little gained by keeping cattle up after the equinox; there may not be much grass to look at, but it will grow, and what there is will be young and sweet.

It is almost time to drill Thousand-headed Kale. We intend putting a small acreage in early in April for autumn feed.

REMARKS.

- 14th.—Spots of rain early, wet from 10.30 A.M. to noon and 9 to 10.30 P.M.; fair between, and a gleam of sun at noon.
 15th.—Sunny early and between 8 and 4 P.M., otherwise overcast, with rain from 11.30 A.M. to 2.30 P.M. and at 6.30 P.M.
 16th.—Overcast, with frequent rain in morning and evening; generally sunny in afternoon.
 17th.—Occasional sun in morning; frequent rain in afternoon, and heavy rain at 10 P.M.
 18th.—Very rough and wet till 10.30 A.M., much bright sunshine from 11 A.M., and bright night.
 19th.—Brilliant from sunrise to noon, frequently cloudy, with high wind after.
 20th.—Bright and sunny till 11 A.M., cloudy after.
 A wet and rather warm week.—G. J. SYMONS.

BARR'S EARLY DWARF "BEST OF ALL" CAULIFLOWER.

Remarkably early, dwarf and compact, with heads as white as snow.

Per Packet, 1s. 6d. and 2s. 6d.

BARR'S CHAMPION SOLID WHITE CELERY.

Very solid and sweet, remaining longer in condition than any other White Celery.

Per Packet, 1s. and 2s. 6d.

BARR'S NEW THICK-FLESHED TOMATO.

Surpasses all other Tomatoes in depth of fruit, solidity of flesh, high quality, and heavy cropping. Per Packet, 1s.

BARR'S SPECIALTIES IN FLOWER SEEDS FOR 1897.

BARR'S SUPERB MIXTURE OF GLOXINIAS.

Seed saved from a selection of the finest named varieties. Certain to please. Per Packet, 1s. 6d., 2s. 6d., and 3s. 6d.

BARR'S EXTRA SELECTED LONG-SPURRED COLUMBINES.

A very choice mixture. Flowers of great beauty in form and colour. Per Packet, 2s. 6d.

TREE LUPINS, mixed, saved at the "LONG DITTON" Nurseries from 10 beautiful delicate shades. Per Packet, 1s.

BARR'S NEW SEED GUIDE FOR 1897

will be sent free on application.

BARR & SONS, 12 & 13, KING STREET, COVENT GARDEN, LONDON.
Nurseries at LONG DITTON, Surrey, near to Surbiton Stn., S.W.R.

ORCHIDS.

CLEAN HEALTHY PLANTS AT LOW PRICES.

Always worth a visit of inspection. Kindly send for Catalogue.

JAMES CYPHER,
Exotic Nurseries, CHELTENHAM.

LILIUM AURATUM.

The beautiful golden-rayed Lily of Japan. Magnificent for pots in the greenhouse, or for growing in the open garden. Deliciously scented, quite hardy. Planted now will bloom splendidly during the summer and autumn. Extra fine roots, 10 to 11 inches circumference, per doz., 7s. 6d.; 6 for 4s.; or 25 for 14s. Grand selected roots, 11 to 13 inches circumference, per doz., 12s.; 6 for 6s. 6d.; or 25 for 21s. All post or carriage free for cash with order.

DANIELS BROS., Town Close Nurseries, NORWICH.

CARNATIONS.—Clearance Sale.

A grand collection of choice named double flowered, in beautiful variety, including all the finest sorts. Strong plants from single pots, correctly named, per doz., 4s. 6d.; six for 2s. 6d.; or 25 for 8s. Double crimson Clove, deliciously scented, per doz., 3s. 6d.; six for 2s.; or 25 for 6s. 6d. Packing and carriage free for cash with order.

DANIELS BROS., Town Close Nurseries, NORWICH.

CHRYSANTHEMUMS.

CLEARANCE SALE.

A splendid collection, including all the most beautiful and popular of the Japanese and incurved varieties; strong, well-rooted cuttings, correctly named, per doz., 1s. 6d.; per 100, 10s. 6d. Extra choice sorts, per doz., 2s. 6d.; per 100, 15s. Six grand new exhibition varieties splendid, the set 8s. 6d. All post free.

DANIELS BROS., Town Close Nurseries, NORWICH.

FUCHSIAS.—Clearance Sale.

A magnificent collection of superb double and single flowered varieties, including the newest and most beautiful sorts in cultivation. Splendid for pot culture or the garden. Strong young plants, from single pots, correctly named, per doz., 2s. 6d.; six for 1s. 6d.; or 25 for 4s. 6d. Extra choice sorts, per doz., 3s. 6d.; six for 2s.; or 25 for 6s. 6d., post free.

DANIELS BROS., Town Close Nurseries, NORWICH.

NO. 875.—VOL. XXXIV., THIRD SERIES.

Barter's IN VICTA GRASS SEEDS

FOR

Garden Lawns, Tennis Lawns,
Croquet Grounds, Bowling Greens,
For Shaded Places.

Entirely Supersedes Turf, which is always full of vile weeds.

Old, worn out, and mossy pieces of Grass can be renovated at little expense if the following directions are attended to.

Lightly scratch the surface with a rake, to make a bed for the Seed, which sprinkle over the ground at the rate of 1 lb. (costs 1s. 3d.) to every 500 square feet, and the contents of a 3s. box of Carter's Lawn Manure (No. 1 prescription); cover the whole with a barrowful of good clean loamy soil. Brush it over the ground, then thoroughly well roll down. Choose a dry day for the work, and where the Grass is very thin do not stint the Seed. If there is no rain within a few days after sowing, and dry winds prevail, a good watering is desirable. Do not cut too closely at the first two mowings.

Estimates for Quantities on application.

CARTERS' PAMPHLET
ON THE MANAGEMENT OF LAWNS,
FREE, FOR ONE STAMP.

Barter's New and Improved Flowers

CARTERS' HOLBORN PRIZE PRIMULA.

We commenced growing and saving our own seeds of this popular winter-flowering plant forty years ago, and have since carefully selected and improved our strain, that we unhesitatingly pronounce it the finest in cultivation; and as we try all others each season for comparison, our statement is authoritative. We were the originators of the Blue Primula, which resulted in some cross-breeding experiments we were making to this end; and were awarded a First-class Certificate by the Royal Horticultural Society, in 1882, for the first Blue Primula ever offered. Our collection also comprises the following beautiful colours:—Scarlet, Carmine, Magenta, Ruby, Vermilion, and White, all of which originated at our Nurseries, and are the most approved types at present attainable.

Each separate, in sealed packets. Price 2s. 6d., 3s. 6d., and 5s., post free.

All Colours, Mixed, in sealed packets. Price 2s. 6d., 3s. 6d., and 5s., post free.

CARTERS' BRILLIANT PRIZE CINERARIA.

Our House has long been famed for this beautiful flower, and our strain is unequalled for profusion of bloom, size of flower, and general habit. We grow all our own seeds, and test other strains each season. A magnificent group exhibited at the Royal Botanic Society's Show, in the spring of 1896, easily gained the First Prize.

In sealed packets, 2s. 6d., 3s. 6d., and 5s. each, post free.

CARTERS' VICTORIA PRIZE CALCEOLARIA.

Our fine strain is well known at all the leading Horticultural Exhibitions, where magnificent specimens have secured First Honours on nearly every occasion.

In sealed packets, 2s. 6d., 3s. 6d., and 5s. each, post free.

ILLUSTRATED CATALOGUE, Post Free.

Journal of Horticulture.

THURSDAY, APRIL 1, 1897.

DIGGING AND FORKING.

GARDENING presents an ample variety of subjects for the studious worker, and even the apparently simplest operations contain in their principles and the method of application abundant material for observation and reflection. The following remarks are not, however, intended for the "old hands," but for the "youngsters" who are eager to learn, and who, I know from long experience, look to the Journal for the practical instruction that is so much appreciated in the novitiate stage.

Important as it is in all its bearings, digging is a part of a gardener's work which should be thoroughly mastered as early as possible. It may be that there are a few "kid glove" young gentlemen in gardens who would almost think themselves disgraced if called upon to handle a spade; but happily they are rarities, and every young man blessed with "a sound mind in a healthy body" should regard "digging" as an essential portion of his education, the acquirement of which may be accompanied by back-aches and arm-aches, but which is nevertheless excellent training for the muscles.

There is an old adage to the effect that "A bad workman quarrels with his tools," but it is equally true that a good workman cannot do his best with bad tools; a preliminary word or two may, therefore, be devoted to spades and forks in connection with our subject. It is my opinion, founded on long experience and close observation of workmen, besides having had to perform no mean share myself, that spades are commonly made too heavy and too large. The object in all manual labour should be to secure a maximum of efficient work with a minimum expenditure of strength, and anyone who has watched a man struggling with a heavy spade must be conscious that neither of these conditions is being fulfilled.

Spades furnished with ponderous blades, 8½ inches in diameter by 12½ inches in length, which are the dimensions of a No. 3 size of some makers occasionally seen in gardens, are more adapted for a pre-historic giant than the ordinary run of young gardeners, muscular though most of them are, happily. In very light soils it is possible to use such spades to some purpose,

NO. 2531.—VOL. XXVI., OLD SERIES.

but in those of a more substantial nature they are worse than useless.

An instrument with a hard steel blade, that has been worn down to about 9 inches in length, is much better suited for ordinary surface digging, and even for trenching or double digging two spits or 18 inches is sufficient depth for the majority of garden crops. Men naturally prefer a spade that is used with the least labour, and the affection they display for their old worn instruments is remarkable; but though this may be chiefly prompted by a regard for themselves, yet I am certain that they usually do more work, and in a better manner, than if they are burdened with larger tools. For ordinary use in moderately heavy soils, a blade $7\frac{1}{2}$ inches by 10 inches is quite large enough.

The size of a fork is of less consequence than strength, for this is one amongst the garden tools that should be made of the best quality material, particularly where there is much rough heavy work to be done. Either four or five-tined forks can be used, and in light soils the instrument known as a Potato fork—*i.e.*, with flat tines—is extremely useful where soil-stirring only is required, and the cultivation has been good for some time.

The method of using the spade requires attention, for there are several labour-wasting ways which seem to be learnt naturally if not corrected. Some men hold the spade with the handle in the right hand, lifting and turning with the left, while others reverse the process, the right hand doing the lifting. In my experience I have found that the majority adopt the former method, and though there is little difference in the quality of the work performed by good workmen in either way, yet I believe that if two men are evenly matched in strength the one who uses his right hand for lifting can do the greatest amount of work, unless he be a left-handed man. The hand and arm engaged in lifting the soil has considerably the greater strain to bear, and it seems unreasonable to tax more severely what is usually the weaker arm.

A few men can work both ways equally well, which is useful when two are together, or an awkward piece of ground has to be finished. The right or left foot is used to force the blade into the soil according to the way the man is digging, but even in this simple matter I have found young men at a loss. If the spade is held at a slight angle one firm pressure with the foot should force it into the soil to the top of the blade, but too often several little jerky pressures are given, that an old instructor of mine used to call "dancing" on the spade, which is a waste both of labour and time.

Except for rough digging in autumn or early winter, when frosts are expected to do the breaking down, it is not desirable to take a great thickness of soil for each spit. Some, with the object of getting over the work as quickly as possible, will take as much soil as the spade will hold every time, and the result is in heavy soil that the clods are rarely reduced properly, and they harden into dry unworkable lumps. A moderate thickness of soil turned completely over and broken down gives far better results in exposing more surface to the air and improving the tilth. This is one point I have found it necessary to frequently impress upon young workmen—namely, that there is a great difference in the methods needed for soil that is to be exposed for some months before it is occupied with crops, and that which is required for immediate use. In the one case the weather performs a greater part of the work, and more efficiently; in the other it must be done as well as possible to secure what is desired—namely, the utilisation of the plant-sustaining properties locked up in every clod of earth.

The necessity of keeping spades clean and bright should be enforced in every garden. One of my rules that I insist upon being rigorously enforced is that all tools shall be properly cleaned at the conclusion of each day's work, and before they are hung up in the tool house. When once a spade or fork becomes rusty it detracts considerably from the ease of working until it has been brightened by use.

Most of the remarks in reference to digging are equally

applicable to forking; but in a general way it may be taken as a subsidiary operation, either preparatory to digging later on or to follow that done roughly in the autumn. It is usually a less thorough means of ameliorating the soil, but is useful where simple breaking down or stirring is of more need than turning, though in fairly holding soils the latter may be accomplished with the fork provided the conditions be suitable.

The objects of such an important operation as digging should be thoroughly understood, for it is a knowledge which guides the hand. It is astonishing what an immense amount of plant food a fairly fertile soil contains, and a large proportion of this can be prepared for utilisation by plants by working the soil in digging and other operations. Some years back Dr. Voelcker examined the soil on good farm land in Hertfordshire, and the result of his analysis, we learn on the authority of Mr. T. Francis Rivers, showed that in the first 6 inches depth there were the following quantities per acre of important elements or compounds. Phosphoric acid, $2\frac{1}{2}$ tons; potash, $5\frac{1}{2}$ tons; lime, 37 tons; magnesia, $4\frac{1}{2}$ tons; sulphuric acid, $2\frac{1}{2}$ tons; nitric acid, 22 lbs.; and nitrogen, 1 ton.

Moderately heavy soil, such as is suitable for fruit trees, taken to the depth named—*i.e.*, 6 inches from the surface, would average about 1000 tons per acre, or 50 lbs. to 55 lbs. per square foot. So that the proportions named may be regarded as approximately those in 1000 parts by weight of the soil referred to—*i.e.*, phosphoric acid 2.5 per 1000, potash 5.5 per 1000, and so on. This is the most striking illustration known to me of the wealth locked up in a good soil, and serves to show what it is the object of digging to aid.

The more soil is stirred and exposed to the air the quicker are the chemical changes which reduce insoluble substances to a condition in which they become available as plant food. Further, by permitting the air to enter freely the soil is rendered dryer, and therefore warmer, besides being more readily permeable by the roots. With judicious use of the spade, the fork, and the hoe a man can in some soils be partly independent of manure, or what is equally to the purpose, he can turn to the best possible use whatever is applied.—PRACTITIONER.

CUCUMBER AND TOMATO TROUBLES.

(Concluded from page 175.)

AMONG other advice given by scientists we are told that directly a plant is affected by the black stripe it ought to be pulled up, and the soil it was rooting in either wholly changed or disinfected with lime, phenyle, and the like prior to putting out another plant. That is what we do when the affected plants happen to be quite small, but if the disease is not noticed till after the plants are 2 feet and upwards in height they would have to be in a very bad plight indeed before I should advise rooting them out. Instances have come under my observation where, if all the affected plants had been removed, few or none would have been left standing.

Market growers cannot afford to miss the best part of a season in that way. What they ought always to do is to raise a few score more plants than they think of planting in the first instance. These will be found handy for filling up blanks that may occur from any cause, also, if my advice is taken, they will shift a considerable number of plants into 11 inch or larger pots. These may be stood among the rest till the plants become tall enough to shade and injure each other, when they may be turned to good account either for taking the place of comparatively strong plants that have become badly diseased, or they may be arranged along the walks at the ends of the houses or other positions that can be found for them. The plants must be slightly sunk in the soil, well supplied with water and liquid manure. Thus treated they will do well, as the roots are certain to spread out of the drainage into the border.

Nothing I have tried by way of a dressing applied to the foliage and stems has done anything towards checking the spread of the black stripe; but by attending well to the roots, not omitting a dose of phenyle, and maintaining a warm dry atmosphere, the bulk of the diseased plants have "grown out of it," the later supplies of fruit being heavy and free from disease marks. A friend of mine with whom I have compared notes has had a very similar experience. Most of his affected plants "grew out of it" last season.

The foregoing was penned in response to an "Anxious Inquirer," who wished me to specially advise upon the treatment of diseased plants.

The "yellow spot," or *cladosporium*, though not so troublesome as it was six or more years ago, has still to be reckoned with by both market and private growers. It would really appear that private gardeners have more cause for complaint than market growers, this being due to the fact that they are not always in a position to give Tomatoes special treatment. When Tomato plants have to be grown in vineries, Peach houses, and forcing pits generally, they cannot always be treated to a warm, dry, airy atmosphere. They get the heat, but it is accompanied by too much moisture, and that is just what favours the spread of the mildew-like *cladosporium*. Before this disease was introduced from America (that is where I say it came from, with Tomato seed) I could grow Tomatoes with Cucumbers and Melons; but it cannot be done now—at least, not by me. Luckily, this highly contagious disease seems to be "wearing itself out," or may I say that an improvement in our methods of culture of market growers' plants is responsible for the comparative immunity from it? It is now generally known that an excess of moisture in the atmosphere leads to the appearance and favours the spread of this once much-dreaded disease; but if by affording fire heat and ventilating freely we can bring it to a standstill, who will be foolish enough to begrudge the cost of the fuel or neglect this timely attention? Market growers are particularly warned against any false economy in the matter of fuel for these and other reasons which will presently transpire.

A few hours' stagnation in the atmosphere sends the disease rapidly through a crowded house of plants, and there are days when this cannot be prevented without the aid of fire heat. Some of the disease will find its way to the plants in spite of all preventive measures—at least, such is my experience—and the question is, What is the best that can be done towards eradicating it? Spraying with the Bordeaux mixture was to have been as effective against *cladosporium* as it has proved against the Potato disease; but one trial of that remedy was quite enough for me. All things considered, it did more harm than good. Such a mess it made, too, of the fruit and everything else it lodged on. Next I tried what could be done with sulphate of copper and lime in a powdered form, and by means of bellows distributors coated the foliage and fruit of hundreds of plants with this pungent mixture. My men were not sorry to hear that none of the sulphate of copper and lime mixture was to be applied last season, and the boys missed the tedious occupation of wiping the ripe fruit before it was packed. I believe it checked the disease, and so it did the growth of the plants, and if it is ever used again it will be as a last resource.

Sulphuring the hot-water pipes and turning on the heat so as to generate fumes strong enough to make the eyes tingle is more to the purpose, and so is making the pipes hot on a warm day. A dry heat of 100° or rather more, accompanied by a little top air, actually kills the fungus, and that is our principal remedy. It is applied as often as the disease threatens to spread again. The plants must not be kept dry at the roots in order that the atmosphere may also be constantly dry; if a mulching of strawy manure is applied there will not be much moisture arising from the soil, the straw drying quickly and preventing evaporation.

Scarred fruits have been much in evidence of late years. As a rule the scars are only skin deep, and may be easily removed by those who eat the fruit; but all the same it sells badly. Once more the microscope brings to light a disease, but I forget whether or not it has a distinctive name. Anyway, if a name has been found a good remedy has not been given. The Bordeaux mixture and the sulphate of copper and lime in a powdered state have been suggested as a matter of course, but these are doubtful remedies—they are next to worthless in fact. Whether right or wrong in the conclusions I have arrived at, I have yet the satisfaction of knowing that the preventive measures we adopted "worked well." I noticed particularly that large quantities of fruit showed the scar, and worse still, that many more showed signs of decaying at the point after a short spell of extra bright weather. When basket after basket of fruit with decaying centres have to be gathered, mixed with lime, and buried, it sets us thinking.

Clear cold nights frequently follow the hottest days, and unless fire heat is given the fruits become very cold. Try them against the cheek at six o'clock in the morning. Directly the sun strikes on the houses the temperature rises rapidly, moisture condensing on the cold fruit only to be rapidly evaporated directly the ventilators are set wide open. What follows? The fruit, tough in the skin, scars, while much of that less advanced scalds, a soft shrunken patch being the first indication of this, and if there is any disease this is an effect not the cause of those black patches of decay that follow. It is simply a repetition of what sometimes occurs with Grape berries.

Instead, therefore, of discontinuing the fires during hot weather I gave orders to start them at 4 P.M., and to keep the pipes moderately warm all through the night. A "notch" of top air has always been left on during the summer; but this is not enough, and I had them opened wider not later than 6 A.M., an hour earlier if possible, thereby preventing any condensation of moisture, and obviating the equally injurious rushes of cold air. The result of this simple change of treatment more than equalled my expectations. The remedy was found.

Mr. Abbey may explain this away how he may, but he will have his work cut out to convince me that a new disease or a disease of any kind has been responsible for those losses of tons of fruit in various parts of the country. It is to be hoped that the several growers who sent boxes of decayed fruit to me last season will read, mark, learn, and inwardly digest what I have just advanced on this portion of my subject. It should also be added that those who ventilate early and gradually will find that there will be far less difficulty in keeping down the temperatures during the hottest part of the day than is the case when ventilation is deferred till the temperature of a house is risen considerably, and for which the remedy is opening the ventilators widely at one time.

One of the penalties attached to a free employment of fresh loam, especially that taken from the surface of meadows, is a plentiful and most unwelcome supply of wireworms. What these are I need not enlarge upon; what they do is only too evident to those who have used loam in which they abound. They bore into the centre of the underground portion of the stem of Tomato plants, and then eat their way upwards, this meaning death to the plants. Wireworms are easily found in the centre of the stems, that is if they are responsible for the drooping of the leaves, so that their attack can be readily distinguished from all other destructive agencies.

When only a few plants are grown in pots, it is a simple matter to hunt out and destroy the wireworms abounding in the soil, breaking up the lumps of fibrous loam in particular. This plan of pulling fibrous loam into small pieces may not commend itself to those who attach so much importance to having their loam in a coarse condition; but if it is a question of fine soil and no wireworms, or the retention of coarse lumps and what wireworms it may contain, decide in favour of the fine soil. Small ridges of soil may be similarly treated, but hunting for wireworms in the long borders covered by market growers' houses is a "horse of another colour."

A light surfacing of gas lime left on the surface for a month to sweeten, and forked in two months prior to planting, or a dressing of salt, may be of service in freeing the soil of wireworms, but may also be easily overdone, more harm than good resulting. I have never tried feeding the wireworms with rape cake or other delicacies till they burst from repletion, nor have I ever dug in a crop of green mustard with a view to making it too hot for the pests. There is some sense in soaking the ground with hot water, and still more in not depending upon any nostrums. "Catch 'em and kill 'em" is the best motto. Nothing easier, nothing safer, nothing surer. When the plants are put out, plant baits at the same time. Insert short labels or pointed sticks in 2-inch lengths of Carrots in preference to Potatoes, plunge these just below the surface midway between, or not far from the plants, and every second day draw out of the ground, remove all wireworms protruding from them, and return the baits to the ground. Wireworms much prefer Carrots to Tomato stems. I have had two boys at this kind of work morning after morning, and whole potsful of wireworms to destroy. It was a case of death to the wireworms, or no Tomatoes. Can anyone suggest a better remedy? If so, please let us have it.

One more trouble and then I have done for the present, always provided I am allowed to remain quiet. Woodlice and crickets are an "awful nuisance" in many market growers' houses, the strawy mulchings and excellent cover afforded by the hot-water pipes resting on the soil favouring the increase of these destructive pests by millions. As a rule they are slow in eating young Tomato plants, but will "bark" them wholesale if no other food is available, while Cucumbers seem exactly to their liking. I have tried drenching with insecticides, including petroleum mixtures, but they seem uninjured by these, and woodlice actually crawl out of crude petroleum. Hot water rolls them over, as well as crickets, and is by far the best remedy I have tried. All the heat is turned on to a flow and return pipe in the houses we wish to clear of woodlice and crickets, and if a good fire is going the water quickly becomes hot enough to kill these insects. Their favourite haunts are drenched with it, and in the Cucumber houses heaps of dry moss placed for their special benefit are also drenched. If this is followed up it is not many that will survive.—W. IGGULDEN.

HARDY BULB CULTURE IN ENGLAND.

[By F. W. BURBIDGE, M.A. Read before the Birmingham Gardeners' Mutual Improvement Association.]

(Concluded from page 245.)

THE best bulb soils are deep, rich tracts of alluvium or "Trent Warp," beside rivers, or in valleys near the sea. In Lincolnshire there are deep sandy soils, not unlike those of Holland, on which most bulbs thrive well. Near Caistor very fine flowers and bulbs are grown, and so also in the neighbourhood of Boston and Wainfleet. Messrs. Pearson & Sons of Chilwell, Notts, have been very successful in growing Narcissi, as also many market growers in the Thames valley, and especially Mr. James Walker, formerly of Whitton, and now of Ham Common, Middlesex, who was one of the first growers to make a speciality of Narcissus culture for the London markets.

In planting stock bulbs do not plant too deeply. It is true that the finest flowers are those produced by bulbs deeply planted, especially on light, warm, and sandy soils, but such flowers are produced later, and the bulbs' increase is much less than when shallow planting is the rule. A depth of 3 to 4 inches is ample on ordinary soils. It is most important to replant stock bulbs as early as possible, and to perform that operation during dry weather. Plant dry and on a firm bottom. All stock should be planted at latest before August, if the best of results are desired.

Sloping land or banks amongst sheltering rocks, totally inaccessible to horse or plough, may often be made profitable by the spade and bulb culture. I have seen the wind and spray-swept Scilly Islands, and the thrifty flower plots along the rocky Riviera, and I am sure that along our English shores there are sheltered and well-watered spots now lying waste, where many things, if not everything, would be possible to the intelligent bulb grower. It is almost incredible, but it is true, that one hundred thousand (100,000) Hyacinths or Narcissus may be grown on an acre of land. Of Tulips, 115,000 to 120,000 may be grown on the same area; and when we come to such small fry as Crocus, Snowdrops, Squills, Anemones, Winter Aconites, and others, the numbers run up to 200,000 and 300,000 per acre.

Bulb culture often means a double profit, because if produced early the flowers are a valuable crop, and a remunerative bulb harvest still remains. The best results will be obtained by utilising light and airy greenhouses in which to forward or develop the earliest flowers, and in such structures in the sheltered, sunny nooks by the sea, before mentioned as most suitable, but little fire heat will be necessary. These greenhouses are of course available for Tomatoes, or other cultures after the bulbs are over. I shall not go into the price of bulbs per 1000 in order to show you how very profitable bulb growing must be on all suitable soils when undertaken by people who understand the subject. There are several factors that must agree in bulb culture, as in all other ways of making a living off the land.

First, the land must be that naturally most suitable to the kinds of bulbs grown, and naturally or artificially well-sheltered; secondly, the cultivator must not only know how to grow his bulbs well, but how to put them on to the best markets; and thirdly, only the best kinds or varieties popular in the market must be largely grown. In special cases a combined course of culture is better than a simple one—that is to say, fruit trees and bulbs may both occupy the same acreage with advantage, or bush fruits and choice vegetables may also be grown side by side with the bulbs; but on soils especially suitable in sheltered aspects, no culture I know is more surely remunerative than bulb culture. Nothing but a new railway, or the most liberal of building contractors, can induce the successful bulb grower to move on and vacate his holding.

To new beginners the selection of the land is a complex problem—to the experienced it is less difficult. Now and then an accidental clump of bulbs or a fruit tree tells the tale. A practical bulb grower has a seventh sense, and knows as it were by instinct when he sees a suitable bulb soil; but, if at all possible, an actual trial of bulbs of all kinds should be made, when they will soon give evidence of the best, as to the suitability or otherwise of the land. As Arthur Young long ago said, no rental is too high for the best land, and none too low for the poorest of soils; and land that will grow bulbs and fruit to perfection is often to be had at a reasonable rate.

An acre or two of good bulb land will pay better than 10 acres of ordinary farm or garden produce, and I should not like to say the value of a rood even, of such select Daffodils as Madame de Graaff, Golden Bell, or Glory of Leyden—to say nothing of choice sorts that are rare, such as Monarch, Weardale Perfection, Hodsock's Pride, or the big and beautiful Ellen Willmott. The same is true of most of the Rev. G. H. Engleheart's seedlings, not alone of Daffodils proper, but of other sections such as Peerless or Incomparables.

Any hardy bulbs that are worth more than £1 per 1000 in the market will pay to grow. Sound and heavy bulbs, as clean skinned as possible, find a ready sale even though not quite so perfect in form and in coat or skin as those from abroad. I have had bulbs of this class by the thousand from Scilly and the Isle of Wight sent tied tightly in sacks like Potatoes, and they flowered as well or better than the finest Dutch roots packed in buckwheat chaff and paper. The rough exterior of a bulb is not always an indication of its flowering qualities. A smooth skinned and shapely bulb looks better in the store or shop, but it does not always behave better in the garden. All large, sound, and heavy bulbs, even if rough coated, may be trusted to bloom well. As to the comparative merits of Continental *versus* English bulbs, I may say that while I believe our friends in Holland can, or rather do, produce the best Hyacinths, and perhaps also some early Tulips, yet we in England and Ireland can grow by far the best Narcissi, late Tulips, Snowdrops, and Crocus of all kinds. So far as Narcissi are concerned we can defy the world, both in rearing new and in growing all other varieties to the greatest perfection of luxuriant health and beauty.

It is not easy to find out how much is paid by us for imported bulbs from all sources every year, but it must be an enormous sum, and a very large proportion of it might be spent at home in the encouragement of bulb culture on English soil. I am a believer in free trade and in all fair trade; but above all do I believe in our home trade and in our home industries. Finally, I believe that every bulb-grower should also devote some of his leisure to rearing new hybrids and seedlings, so that there may be progress ahead, as well as lateral diffusion in bulb culture.

What Leeds, Backhouse, Herbert, Horsfield, Engleheart, and De Graaf have done, may be equalled or surpassed by other cultivators. Beautiful as are the finest of our new seedlings to-day they are not perfect in all ways, and there is room and a welcome for many more equal or superior to them. It may not be so profitable to rear seedlings as it is to grow quantities of older kinds in good demand, still, given a perfect bit of Narcissus soil, I believe it would soon pay for a clever grower to take up the special culture and increase of all the rarest and most beautiful new kinds. The best varieties of bulbs to grow of course depend on soil and climate, but all the best Narcissi, self Tulips, Squills, Anemones (especially *A. fulgens*), Gladioli, Crocus, and Snowdrops, are profitable crops wherever they will thrive in quantity, and these may be supplemented by other and rarer kinds.

It only remains for me to acknowledge the honour your Association has conferred upon me by requesting me to read a paper before your members; and, having many friends, and many pleasant memories of former visits to Birmingham, my deepest regret is that I could not come over in person. Your city is, and has long been, a centre of horticultural energy and progress, and a history of that constant progress would form one of the most interesting of papers that could be read before you, and one that I hope our good friends Mr. W. B. Latham or Mr. W. Spinks will take the slight trouble of laying before your Association.

[By error we stated in our last issue that Mr. W. Sydenham was present at the reading of this paper; it should have been Mr. Robert Sydenham.]

HYDRANGEAS.

THIS very useful plant being so rarely seen well grown I thought a few remarks on its somewhat simple requirements might be useful to many of your readers. Several growers depend year after year upon their old stock, which with proper management may be grown to give excellent results. We prefer, however, to keep weeding the oldest out and filling their places with younger and stronger plants, which are flowered in 6-inch pots. I have no hesitation in saying that cuttings rooted early in the year and treated in a similar manner to an ordinary bush Chrysanthemum in mode of stopping would the following year produce twenty fair-sized heads of bloom in a 6-inch pot.

Immediately the plants have passed their best we prune them hard back, place them in a warm pit, dewing them over with the syringe two or three times daily, and when well broken they are shaken out and repotted in not too light a mixture, though rich, and placed back in the warmth, where they are allowed to make a good portion of their growth, afterwards gradually hardening them till they are able to stand outside on a bed of coal ashes, under partial shade during the hottest part of the summer. Weak applications of liquid manure are given each watering until the growth is completed, when feeding is stopped.

The plants are allowed to remain outside to get a slight frost to remove the foliage, and are subsequently laid on their sides under the greenhouse stage until the desired time for starting has arrived. The variety I specially allude to is Thomas Hogg, of which we grow about fifty, starting a few at a time to form a long succession. We have at this moment about a dozen plants carrying eight to twelve trusses of bloom in 6-inch pots. These when neatly staked form useful plants for table decoration, though their value is most appreciated for church decoration at Easter.—T. SNELL, *Grimston*.

HAMBURG EXHIBITION.

WE are informed that Baron Sir H. W. Schröder, The Dell, Egham, is sending to the Hamburg Exhibition a collection of his magnificent Orchids. Sufficient will be forwarded to make an exhibit occupying a space equal to 55 square yards. It is probable that the quality of the Baron's Orchids, as grown by Mr. Ballantine, will be a surprise to considerable numbers of our German friends.

DENDROBIUMS IN BEAUTY.

THOUGH the beauty of individual plants of good species and varieties of Dendrobiums is well known and thoroughly appreciated, the sight of a large collection in full flower always claims a wonderful amount of admiration. There is a brightness of colours in one, a depth of tone in another, a softness in a third, and an exquisite harmony in a fourth that maintain the interest and appeal with irresistible force to everyone's sense of beauty. Interesting as is the Veitchian collection of Orchids at all times, no visit was ever more enjoyed than that made recently to see the Dendrobiums in beauty.

Scores of plants were blooming profusely, representing several sections, and inclusive of such as Wardianum, crassinode Waltoni, Dulcie, nobile Cooksoni, Euosmum, splendidissimum, Veitch's var., Wigani, Edithæ, atro-violaceum, Endocharis, nobile Sanderiana, and many others. These names will, however, suffice to show the diversity of the plants that were then in flower. It is surprising how healthy the Chelsea plants always look when the smoke-laden atmosphere in which they are growing is taken into consideration, and Mr. Harris, Messrs. Veitch's grower, is deserving of credit for the incessant care and skill he must accord to them.—VISITOR.

CYMBIDIUMS.

WITH the exception of one or two well-known species Cymbidiums are not popular Orchids, the most grown and most admired species being *C. eburneum* and *C. Lowianum*. It is a very widely distributed genus geographically, the habitat extending from China and Japan in the East to Western India, a few kinds also hailing from Madagascar and the Australian Continent. As a rule, I am told the larger members of the genus grow in the vicinity of water, sometimes being in fact almost in the bed of mountain streams, and this doubtless accounts for their liking for atmospheric and root moisture.

In most instances the roots are large and fleshy, liking a substantial compost and good root room. The smaller growing species of course do with less of the latter than such as *C. giganteum* or similar kinds; and the compost, too, may with advantage be kept a little lighter and more open. Equal parts of peat fibre, loam, and sphagnum moss suit them well, abundance of rough crocks or charcoal being added to this, and also a little dried cow manure or some artificial fertiliser for the stronger growers. The majority do best in pots of suitable size according to habit, and these must be thoroughly clean and well drained, a layer of rough moss being placed upon the crocks to prevent the finer particles of the compost from silting down among the drainage.

Healthy plants usually produce roots in such abundance that the pots are entirely filled with them; they enwrap every bit of compost, and cling with tenacity to the sides of the pot. In such a case it is obviously impossible to spread the roots out, and beyond picking out a few of the lower crocks nothing is needed in this way. A pot large enough to allow a couple of inches of new material all round must be given, and this should be firmly placed with a thin potting stick, but not rammed. On the surface a little new material should be laid and trimmed off neatly, bringing this well up to the base of the last formed pseudo-bulb.

Should the plants by any means have got into bad condition at the roots turn them out, and remove all the old material from

about them. Any that are dead or far gone should be cut clean out with a sharp knife, and it is just as well to wash the living roots that are left and the bases of the old bulbs in tepid water before repotting. A lighter make up of material may be used for this class of plant, leaving out the manure and most of the loam, adding more moss, charcoal, and crocks in the place of it. They are better, too, for a little nursing afterwards, a little more heat and atmospheric moisture, the compost being kept rather on the dry side.

With regard to temperature, such kinds as *C. eburneum*, *C. giganteum*, *C. Lowianum*, or *C. Mastersianum* are often kept too hot. They are quite at home in a cool, moist house such as suits greenhouse Ferns, and may be, in fact often are, well grown with them. Here one seldom comes across cases of flower bud dropping that used to be so frequent in plants grown too warm. The foliage and bulbs take on a deeper green, insects are less often seen about them, and they are more satisfactory in every way. One of these species at least—*C. giganteum*—has been known to withstand frost; but this, of course, is carrying cool treatment much too far.

From the time they begin to grow until the pseudo-bulbs are finished, and in some cases until the flowers are open, these plants require almost aquatic treatment. Owing to the open condition of the compost the water rapidly gets away, and almost daily applica-

FIG. 59.—CYMBIDIUM TRACYANUM.

tions are required when the weather is bright. During the winter evaporation is of course slower, and root action not quite so brisk, and in consequence less water will be needed. But by this it must not be inferred that they require drying, as this treatment is about the worst possible for them, and weak, puny, oftentimes flowerless growths are the inevitable result. Endeavour then to strike a medium course that will keep the plants plump and healthy, yet not damage or surfeit the roots.

Abundance of air is also of great help. Early in the morning before the sun reaches the house let the top ventilators be opened a little to let out the night moisture. This chink of air can be increased as soon as a slight rise in temperature is felt, and by this gradual increase the foliage will be kept cool, and it will not be necessary to shade the plants so soon. Thus the plants get a nicely tempered and evenly balanced atmosphere combined with plenty of light, and this will go a very long way towards their successful cultivation. There is not space to describe the flowers of these useful Orchids; but all are beautiful, if not very showy, while many combine the two qualities. In most cases they are very long lasting, and often the blossoms are of the most delicate perfume. The beautiful *C. Tracyanum* (fig. 59) is not so well known. In the growth and foliage with the smooth stem or leaf bases it resembles *C. longifolium* or *giganteum*, but the flowers are of great size, 5 inches or more in diameter, with broad sepals and petals evenly and strongly veined or spotted in lines of a reddish tint on a yellow ground. The lip is long and broad, pale yellow spotted with red. The raceme was about 4 feet long, bearing numerous flowers.—H. R. R.

SPRING SCENES.

"SPRING'S Delights" are seen everywhere now in fields, lanes, on banks, and in woodlands, as in gardens. For some time past I have been watching a *Pyrus japonica* on a wall. At first there seemed no sign of life, then a slight swelling of the buds, which increased perceptibly, and now a blaze of scarlet. It was an old tree, open to the public view, and beautified a wall that perhaps would otherwise have been bare. It was a happy inspiration that guided the hand which planted it. In the shrubberies *Pyrus malus floribundus* and others are covered with their wealth of blossoms, and one notices here and there the telling flowers of some of the earliest *Rhododendrons*, such as *fulgens* and *Nobleanum*. "What is that which smells so sweetly?" was asked the other day when walking round a garden. Soon we learnt, and I may say that the *Daphne Mezereum* is without a rival at this time of the year for its delicious odour. There they were, large bushes, both white and pink, and a mass of bloom—surely one of the most charming of Spring's pictures.

Recently there appeared in these pages a brief note on the "London" Almond trees, as the writer aptly termed them, for they seem peculiarly at home amid the outside show of the modern builder. Everywhere in the suburbs of the metropolis one sees them, where they form the brightest of spring scenes. One might go on enumerating the flowering shrubs and trees that are and soon will be features in the garden, but we have other scenes to note.

Everyone is thinking of Daffodils just now, and here we mark the hold which these flowers have during the past few years taken on public favour. I do not wish to assume that the nodding Daffodil has not always been popular to a certain degree, and I remember how in the orchard adjoining an old farm house we used to watch the yellow flowers unfold with pleasure, intermingled with some anxiety that they would be out for the Easter decorations. Under the shade of orchard trees seems to be the true home of the double Daffodil, and it would be difficult to point out a site where they look more charming. The clumps referred to were not cultivated; they grew themselves, yet their non-appearance at this time of the year would have been the talk of the country side. When they were planted no one knew, nor took the trouble to inquire, so far as I am aware. It would, however, be interesting to learn how these showy flowers in the first place got spread about, as we are told they were first brought by the hardy seamen who came from the shores of the Mediterranean to barter for tin and soft metals with the rude inhabitants of the Scilly Isles and Cornwall. Assuming this to be so, when they first brought their bulbs little did they think of the foundation they were laying of the gigantic industry that was to follow centuries after.

Hybridisers have brought their art to bear on the *Narcissi*, and the enthusiastic grower who would ride his hobby to the latest introductions has to reluctantly tighten the rein when he sees them priced at 2 or 3 guineas per bulb. This brings us to the commercial aspect of bulb growing, and when such an expert as Mr. F. W. Burbidge recommends it as a means of pulling the British farmer out of the quagmire of agricultural depression—well, we begin to think there must be something in it. It seems feasible, too, for why should not English land grow bulbs as well as that of Holland? One hundred thousand pounds is a large sum to pay the Dutchmen annually for bulbs,* and in these days it is of the utmost importance that home productions should be encouraged. At the same time we must bear in mind that the English agriculturist follows the track of his fathers, and is loth to depart from it, even though his banking account may be at a low ebb. Moreover, he knows nothing of bulb culture, and must be taught ere he could make it a success. The question is well worth consideration, and perhaps the future may find us exporting instead of importing bulbs. Let us hope so.

Thoughts of utility have caused me to digress, so to return with yet another word about the beauty of the bulb family. Hyacinths in the beds are pushing their showy spikes, and when planted in masses form one of Spring's most chastely painted pictures. They lack, however, the gracefulness of the Daffodil, or the elegance of form noticeable in the Dutch Tulips. "Plant bulbs in the grass," say able writers on the subject; and here is a scene: A breadth of sward, undulating in surface and interspersed by trees and shrubs. In the glades and on sunny slopes were first the Snowdrops, then the Crocuses, and now the Daffodils, with *Chionodoxas* and others of elegant character. Plant bulbs in the garden borders, on the flower beds—anywhere; but it is when we see them under the above conditions that we appreciate the force of the advice aforementioned.

* Do not the importations exceed twice the amount named? We think so, and are glad to know that *Narcissi* bulbs are largely exported from England, also Snowdrops, the demand for these often exceeding the supply.

Yet another picture—this time Polyanthus, so showy at spring time. "Two things are necessary," said a successful grower of the Polyanthus to the writer. "Firstly, a good strain; secondly, strong plants." There is the whole thing in a nutshell; and perhaps the reason why Polyanthus have lost some of their popularity as bedding plants is because the importance of these points has been overlooked. A good strain means large distinct flowers on stout footstalks, and it can only be obtained by careful watching and saving seeds from the best forms. That reminds us that Polyanthus should be raised from seeds sown in cold frames at this time of the year in preference to the ancient custom of splitting the old plants in the early summer. They have then a long season of growth before them, and are large and sturdy at the time of planting. It would be difficult to speak too highly of a good display of Polyanthus, such, for instance, as that which may annually be seen at Hampton Court. Ardent growers also speak well of them as pot plants for decoration, and if taken up and potted, supplying abundance of water, they will not suffer to any extent. Of the Primrose family the blue form seems to be all the rage now, and a daily paper spoke of it as being the chief feature of a recent Drill Hall show. Blue, forsooth! The other day I saw plants of it varying in shade to the deepest purple, and not a small proportion of the flowers were perfectly white. I would like to hear the opinion of other growers as to whether the "blue" Primrose keeps to its true form, or whether its tendency is generally to turn white with here and there intermediate shades of blue.

These notes would be incomplete without a word about Wallflowers, now so beautiful in the gardens, and so eagerly sought after by flower vendors. What spring flower is more popular in London streets or more plentiful in Covent Garden Market? The very name is applicable, as *Cheiranthus* is derived from *cheir*, the hand, and *anthos*, a flower, according to Johnson's Dictionary, in reference to the custom of carrying the Wallflower in the hand for a nosegay. Many market gardeners in the neighbourhood of the metropolis grow large areas of Wallflowers for sale every year, and as the cost of production is light no doubt the returns are satisfactory. The mild winter has been favourable for the plants, and one particularly floriferous form sent out by Messrs. Sutton of Reading has been in bloom for some time past.

Failures often result from too generous treatment. A gardener lost all his Wallflowers during a severe winter except a few that he had planted in an unmanured corner of a ploughed field. He was observant, and learnt his lesson. Next season the stock was transplanted from the seed bed to the hardest and most exposed piece of ground he could find. The result was sturdy plants, that not only withstood frost, but produced an abundance of flowers, and never after did he have reason to complain of failures with Wallflowers. As the time of seed-sowing is not far distant perhaps the hint may be acceptable.—G. H. H.

THE LATE DR. HOGG.

I REGRET that I was unable to be present at R.H.S. on Tuesday last to join in the general expression of sorrow at the loss of our head authority on fruit, as so well expressed by Mr. Wilks. Allow me, therefore, to do so now, and to say further that I have a keen remembrance of many kindnesses from our "good old Doctor," especially when I first emerged, as it were, from the chrysalis state in the provinces to the Fruit Committee.—GEORGE BUNYARD.

IT WAS with feelings of the most profound regret that we saw the notice of the death of the venerable and respected chief, Dr. Hogg. Especially was his loss felt by us when we know the very high esteem in which our poor father held the Doctor, while we have recently been the recipients of his best wishes for our prosperity. On the part of the horticultural world we feel that a loss has been sustained that will never be made good. To all the members of the Hogg family we wish to convey feelings of our deep regret.—W. AND E. LAXTON.

PERMIT me to add my expression of appreciation and esteem over the finished work and noble character of our leading pomologist, since the death of the late Mr. Robert Thompson of the Royal Horticultural Society of Chiswick. In much, perhaps most, of their best work these two great authorities worked as one man for the advancement of the art and science of horticulture. Those of us who have entered into their labours, to ever such a small extent, can appreciate in a small measure the enormous difficulties these pioneers in fruit culture and fruit classification had to meet and to vanquish. Neither was able to finish his work. But Mr. Thompson and Dr. Hogg made it easier for all true workers in this promising field to achieve greater victories, win more solid profits, and enjoy more satisfying pleasures in the near future than have been possible in the past. Dr. Hogg's "Fruit Manual," in various editions, fed the fire of my ambition to keep as nearly as I could be abreast of his knowledge and industry in matters relating to fruit.

culture, and chiefly determined me to devote my future mainly to the higher development of fruit, flower, and vegetable culture, through the technical education schemes of County Councils.—D. T. FISH.

I FEEL I must join in the universal expression of regret at the loss of our dear old Dr. Hogg. It is over twenty-five years ago that I first met him in the Council-room of the R.H.S. at South Kensington. I was then yearning for knowledge of the names of Apples and Pears then unknown to me, but hardly liked to approach the highest authority with a few pocketed specimens. But on an introduction I was very agreeably surprised to find how affable and agreeable he was to impart any information on fruit to inquirers. For that and other favours I shall ever cherish his memory, and feel that gardeners and horticulturists generally have lost a true friend.—C. ORCHARD.

I SHOULD like, as a young gardener, and I am sure I may say on the part of others in the same domain, to tender our deep sympathy with members of the Hogg family in their bereavement occasioned by the decease of the late Dr. Hogg. The biographical sketch on page 232 enlightened probationers respecting the youthful career of the esteemed Doctor, and what lessons it affords. A successful career, terminated amid universal regret; the possessor of great horticultural knowledge, gained by undaunted courage and energetic enterprise, freely and impartially expounded "for gardening and gardeners." Let us hope that this irreparable loss to the horticultural world may teach us to persevere until we reach the ideal of our ambitions. "The Fruit Manual" is a literary monument, and when those who possess it reflect on the benefit derived by its teaching and guidance the name of the author, the late Dr. Hogg, will find a cherished place in the heart of many a gardener.—H. TURNER.

I WAS very sorry to see that we had all lost the good old "Doctor," and to me it seems like the falling of one more of the staunch old ramparts of the past. I knew him since 1869, when he, Mr. Moore of Chelsea, and the late Rev. M. J. Berkeley formed the Chiswick Garden Committee, and a noble trio they were in all truth.

I remember the dear old Doctor once giving me the kindest and best of advice at a crisis in my life, and though I did not see and take it at the time I have since regretted that I did not do so, as time has proved his advice to have been true, sound, and disinterested.

Ah! in those old days (1868) Chiswick was a garden to see and feel proud of. Though not quite, even then, in its most prosperous time, but it was intact, covering 33 acres, and the things and the men of the best. The fruit room alone was a sight to see, and its like could not now be found in Europe. Certainly not in Britain. George Gordon, Robert Thompson, and Robert Fortune, the Chinese collector, used now and then to visit the former scene of their labours and triumphs, and the visits of the Garden Committee were red-letter days indeed.

One or other of the young gardeners used to prepare a frugal luncheon in the old Council room for the Committee. One day it fell to my share to do this duty, and, boy like, I was most anxious, and had things ready half an hour or so before the time. Then I began to look out for the members of the Committee. Seeing another young gardener at work in an enclosed plot near the Council room I shouted to him, "Hev' you seen 'oud Smellfungus about yet?" This was our usual appellation for Berkeley, the eminent fungologist and Fellow of the Royal Society! "No!" he shouted, and I returned through the doorway of the wall, and almost fell into Rev. Mr. Berkeley's arms! Catching hold of me, he asked, "Who were you calling oud Smellfungus just now?" "Yourself, sir," I managed to stammer, though I felt like sinking into the earth. "Ah! quite right," said he. "Good boy; always tell the truth when you are in a difficulty." Just then Mr. Thos. Moore and Dr. Hogg came up, and by the laughter I heard proceeding from the Council room shortly afterwards I suspected that Mr. Berkeley was telling the story to them.

When I was abroad collecting in Borneo Dr. Hogg did not forget me, but asked Mr. Veitch several times as to my welfare, and he also made me a good offer of employment on my return, which circumstances, I need not now mention, prevented my accepting.

Though I only saw Dr. Hogg occasionally I always found him to be a good and faithful friend, and now he is gone from us I feel that I should be lacking in grateful sympathy did I not lay a tiny green leaf of Laurel and a sprig of Rosemary at his feet.

Words sound thin and poor in the face of death, but they are now all that are left to us excepting our grateful memories of such a noble man.—F. W. BURBIDGE.

It was scarcely possible for anyone interested in horticulture, or those who, like myself, have read the "Journal" year by year, to fail to take an interest in all that the good Doctor said or did. May the force of his example and the value of his life's work never fade.—W. HOLMES, *Guernsey*.

[We have not been able to publish all the communications and kind references that have been received on this mournful subject, and have selected those that were generally representative. The kind expressions tendered, whether published or not, are highly appreciated by the family and coadjutors of the dear old Doctor, as are the generous allusions to the memorable event which have appeared in the horticultural press. Mr. Harrison Weir has proposed, in the *Gardeners' Chronicle*, that a fund be raised for providing a "Robert Hogg fruit medal" to be offered as the highest award for fruit by the Royal Horticultural Society.]

WEATHER IN LONDON.—Again we have to record a week of changeable weather, gleams of brilliant sunshine alternating with drenching downpours of rain. Besides these we have had on several occasions high winds that have combined with the rain to make travelling thoroughly uncomfortable. Sunday, both in the morning and evening, was very wet, the afternoon being bright, fine, and warm, as was the whole of Monday. Early on Tuesday morning there was a white frost, followed by a genial day. Wednesday was dull and showery.

— WEATHER IN THE NORTH.—Gusty winds frequently accompanied by heavy showers of rain marked both days and nights of the former part of last week. The afternoon of Saturday was breezy and cold. Sunday morning extremely wet; Monday bright and sharp throughout, with the hills around whitened by snow. On Tuesday morning 8° frost were recorded.—B. D., *S. Perthshire*.

— GARDENERS' ROYAL BENEVOLENT INSTITUTION.—At a meeting of the Committee of the Gardeners' Royal Benevolent Institution, held at the Offices, 50, Parliament Street, S.W., on March 26th last, the following resolution was unanimously adopted:—"The Committee of the Gardeners' Royal Benevolent Institution desire to place on record an expression of the deep regret at the severe loss they have sustained by the death of Dr. Hogg, Chairman at the anniversary festival dinner in 1876, a Vice-President, and a Trustee. For the long period of fifty-five years Dr. Hogg had taken a keen and active interest in the work of the Institution. He always had its welfare at heart, and his warm support will be greatly missed. The Committee further desire to express their sincere sympathy with Mrs. Hogg and her family in their bereavement."

— THE QUEEN'S JUBILEE AND HORTICULTURE IN SCOTLAND.—The Royal Caledonian H.S. and the Edinburgh Horticultural Association are offering respectively £120 and £150 for extra prizes by way of celebrating our good Queen's Jubilee. It may be asked what lasting benefit will accrue from such prizes beyond a little gratification to the prizewinners, and there it will end. It is quite certain that it would be more in accordance with Her Majesty's feelings, and be a lasting good to the needy connected with horticulture, if the money were given to the Gardeners' Benevolent Institution and the Gardeners' Orphan Fund. To bestow the money as is proposed will not result in a fraction of benefit to horticulture for the present or future years, and will be of comparatively little benefit to the few who may share in it.—OBSERVER.

— THE HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—Mr. Chas. Lawton occupied the chair at a special meeting on Tuesday, March 23d, when a most excellent paper was given by Mr. J. Johnson, gardener to G. Marshall, Esq., Claremont House, Grimsby, on "Odontoglossums." He dwelt upon advantages and pleasures to be derived from such cool-house Orchids as Odontoglossums, it being possible with but a comparatively small collection to have blooms during the greater part of the year provided the cultural details are duly attended to. Every point in their culture is of importance, one neglected item often causing much trouble which would otherwise be avoided.—F. L. T.

— WEATHER AND CROP PROSPECTS IN GUERNSEY.—After a spell of six months dreary dripping weather, we have at last had a bright week or two. The effect of this is already apparent in the improved appearance of all kinds of crops out of doors, and it has also had a very beneficial effect upon the Vines and Tomato plants indoors. These had been badly in need of sunshine—indeed, had not the change come when it did, the "set" of Tomatoes in many places would have been a very light one. The damp sunless weather was causing many of the flowers to drop, and where Grapes were being forced strongly mildew had in several instances made its appearance. Now, happily, all is changed for the better, and should the fine weather continue we may yet have an early season. Narcissi have come and gone very quickly, so that, excepting Ornatus, there will be few left for gathering for Easter. Pear trees, now in full bloom, promise a very full crop. Melons have been pretty extensively planted, and in view of the coming busy season of the Diamond Jubilee these should pay well.—X.

— THE QUEEN'S GARDENER.—We understand that by the gracious invitation of Her Majesty Mr. Owen Thomas will shortly enjoy a fortnight's holiday in the south of France—a sojourn that will no doubt prove to be very delightful.

— EARLY SPRING VISITORS.—Swallows have made their appearance here, two having been seen on Saturday, March 27th, which, I think, is the earliest recorded date. The dates for 1894, 1895, and 1896 were April 4th, 9th, and 3rd respectively. It may also be of interest to some of your readers to know that I cut 100 heads of Asparagus from out of doors on March 26th, which is a few days earlier than last year. The very mild nights and bright days is bringing things on apace.—C. ORCHARD, Bembridge, I.W.

— THE SEASON IN THE ISLE OF WIGHT.—During the month of March winds have been high and rains heavy in the Garden Isle; still vegetation has developed rapidly in all parts of the island. Mr. A. Gell, Sandown, has been pulling Rhubarb in the open air since February 26th; Mr. C. Orchard, Bembridge, made his first cutting of Asparagus on the 26th of March. On Saturday, March 27th, several Pear trees were observed in full bloom in Westhill Gardens, Yarmouth, I.W. In many parts of the island early Potatoes are up, whilst Peas are sown in several gardens. There is an abundant show of bloom in the woods and hedgerows of Primroses, Daffodils, Violets, and Periwinkles.—S. H.

— CINERARIAS AT PERRY HILL.—The beauty of collections of Cinerarias when in full flower has frequently been extolled in the pages of the *Journal of Horticulture*, while their culture has often been described by masters in the art of growing them. A few lines may, however, be devoted to a brief reference to what may be termed a London display, which is now on view at the Perry Hill Nurseries of Messrs. Jas. Carter & Co., High Holborn. There may be found a large house completely filled with splendidly grown plants, carrying thousands of shapely, variously hued flowers. The plants are not so dwarf as those of some other strains, but this, to my mind, is by no means a disadvantage, for it allows of the flowers showing themselves off much better than could otherwise be the case. The individual blooms are excellent in shape, the petals overlapping, with in several cases remarkable evenness. The colours comprise whites, reds, and all shades of blues. The strain is known as Carter's Brilliant Prize Cinerarias.—H.

— POTATO SCAB AND A NEW REMEDY.—The scab disease of Potatoes causes annually an enormous loss throughout the country, and the fact that ground on which the crop is scabby one year is infected with the germs of the disease, which will necessitate its being used for some other crop the next year, is an important factor in some sections where it is not customary to follow a strict rotation. There have been various trials of germicides and antiseptics as preventives of the disease, but Potato growers have generally followed the practice of soaking the "seed" for a couple of hours in a solution of corrosive sublimate, a substance which, while most effective as a germicide, demands that it be handled with great precaution because of its very dangerously poisonous properties. However, its use has been rapidly and largely extending, and we have not hesitated to advise its employment whenever asked to prescribe for Potato scab. Dr. Byron D. Halstead of New Jersey, in the year 1895, made a series of trials which led to the conclusion that flowers of sulphur dusted in the rows acted most beneficially as a preventive, but we do not know that any extended trials with this material were subsequently made. In the search for a preventive it is highly desirable that some less dangerous body than corrosive sublimate be discovered, and it is, therefore, with much delight that we note Dr. J. C. Arthur, botanist at Purdue University, reports favourably on the use of formalin, a substance which has been largely experimented with of late as an antiseptic and germicide by physicians and biologists generally in hospital and laboratory practice, and which has given much satisfaction. As this substance is not dangerous, not expensive, and is a powerful germicide, the preliminary notice just issued is an important vindication of experiment station work. Further information is promised shortly; in the meantime the following quotation will explain the method of use:—"Eight ounces of the formalin are added to 15 gallons of water, and in this the seed Potatoes are soaked for two hours. After being taken from the bath they can be cut and planted as usual, either at once or after some time. Formalin is not corrosive, and so can be used in any kind of vessel, and not being poisonous there are no particular precautions to be observed. It does, however, make the hands smart if there are any raw spots, and the fumes irritate the eyes and throat. But these are only slight annoyances."—"American Gardening.")

— THE NATIONAL AMATEUR GARDENERS' ASSOCIATION.—The National Amateur Gardeners' Association will visit Messrs. Barr and Sons' Nursery, Surbiton, on Saturday, 10th April, leaving Waterloo (South Station) at 2.33 P.M. Return fare to members, 1s. 3d., on application to the Hon. Secretary—LEONARD BROWN, *The Cottage, Seven Arches, Brentwood*.

— "FERNS AND FERN ALLIES."—We have received a small pamphlet containing a list of the Ferns and Fern allies (all the vascular Cryptogams) that are cultivated in the University Botanic Gardens at Cambridge. The list occupies eight pages, and comprises hundreds of names. The preparation must have entailed a considerable amount of work on Mr. R. Irwin Lynch, the Curator, by whom it was undertaken.

— VIOLETS FROM THE NORTH.—As Violets are attracting a good deal of attention at the present time, I am sending you a few blooms of a new variety that originated here a few years ago as a sport from Count Brazza's White Neapolitan. In its charming colour and fragrance it seems identical with the old Neapolitan, but it is a much stronger grower. The flowers are not so large as last year, owing to the plants having suffered a good deal from red spider last summer.—NORTH-NORTHUMBRIAN. [The specimens were excellent, and the variety is evidently well worth growing.]

— POTATO PESTS IN AMERICA.—For some years past Potatoes in many parts of the country have shown unsightly pimples or projections on their surface, which have seriously diminished their value. The cause of this pimply condition has not been thoroughly understood until certain investigations carried on by the New York Experiment Station in Long Island showed that the injury was worked by a small flea-like beetle, well known as the black Cucumber beetle, which has been detected in eating holes into the leaves of the Potato and Tomato just as it does in the leaves of the Cucumber. These voracious insects, however, are not the immediate cause of the mischief, but minute white grubs which are hatched from the eggs laid by the female beetle. These grubs burrow into the tuber and cause the pimples and the sliver-like projections which accompany them. The pimples result, it is probable, from the irritation caused by the worm, and the slivers are slender canals in which a single grub feeds. Either one of these characteristics of the disease may be found without the other. Bulletin 113 from the Geneva Station gives this important information, and states clearly how the disease can be controlled. The Bordeaux mixture, which has been found useful for so many purposes, is an efficient remedy here also, and when thoroughly and intelligently applied it keeps the beetles away from the plants.—("Garden and Forest.")

— WAKEFIELD PAXTON SOCIETY.—"Some Phases of Bird Life" was the title of a most interesting lecture delivered by Mr. George Parkin, at the Paxton Society's meeting, on Saturday evening the 18th ult. Cr. Milnes occupied the chair, and Mr. Herbert Chapman the vice-chair. The Chairman at once made way for the lecturer, who treated his audience to a lecture on some of the less known and less common features of bird life. The various subjects treated were beautifully illustrated with limelight views, ably shown by Mr. Harold Parkin, son of the lecturer. The first picture was a "freak," and this was the only one of the kind shown throughout the evening. Amongst other birds exhibited were pheasants of all varieties, such as the white, or albino pheasants, female birds assuming the plumage of the male; pied birds, with some illustrations of almost white blackbirds; cream coloured starlings, pied sparrows, pied robins, cream coloured swallows, the cuckoo, the renowned great auk, the principal British divers—the great northern diver, the black-throated diver, and the red-throated diver. Some curious specimens of birds' nests were also given, showing the wonderful adaptation to circumstances exhibited by the birds when building. The concluding slides were mostly of sea birds and their homes, the various breeding grounds on our coasts, with such well-known places as Flamborough. The methods employed for obtaining these eggs were also lucidly explained, and examples shown on the screen. A vote of thanks was unanimously awarded the lecturer and the lanternist for their services, on the motion of Mr. Webster, seconded by Mr. L. Dobinson. The Vice-Chairman announced the death of Dr. Hogg, editor and proprietor of the *Journal of Horticulture*, a well-known writer on these matters, and a friend of the Wakefield Paxton Society. He (Mr. Chapman) moved a vote of condolence with Dr. Hogg's family. This was seconded by Mr. George Gill of Eastmoor, a personal friend of Dr. Hogg's, who, on the occasion of his last visit to Wakefield, paid a visit to his garden, admired his extensive and beautiful display of Tulips, and made some interesting comments upon them.

— **SALE OF FRUIT PULP.**—A sale by auction of fruit pulp was held at Lenham, near Maidstone, a few days since, when 1400 tons passed under the hammer. We learn from a Kentish paper that there was a good attendance, and although the prices obtained were not particularly high there was a brisk competition for the various lots. The leading prices obtained for the pulp in bulk were—Damson, 32s. to 40s. per ton; green Gooseberry, 37s. to 55s.; red Gooseberry, 37s. 6d. to 67s.; Raspberry, £18 to £19; Black Currant, £18 to £45; and for the same, two-thirds whole fruit, £26 to £27; Red Currant, 72s. 6d. to 125s.; Morello Cherries, pulped, 25s.; the same, whole fruit, 32s. 6d. to 37s. 6d.; Blackberry, 27s. 6d. to 30s.; Black Diamond Plum, 30s. to 55s.; Victoria Plum, 45s. to 87s. 6d.; Green Gage Plum, 30s. to 50s.; Mogul Plum, 30s. to 32s. 6d.; Orleans Plum, 30s. to 35s.; and Apple, 25s. to 35s. per ton.

— **AMUSING CLAIM FOR PLANTS.**—The Cardiff Burial Board recently purchased some land for the purpose of enlarging the cemetery, and three of the tenants claimed compensation. One of the claims was for £500, and the specified items included the following:—Two hundred Michaelmas Daisies, eleven Polyanthus, five roots of Anemones, three Jacob's Ladders, six Aule major, one Evening Primrose, 4 feet Father Before Son, two Lilacs, eleven pink Carnations, one Sunflower, four hundred and twenty Daisies, one Pansy, two Musks, two Noah's Arks, a further two Michaelmas Daisies, and two Gladioli. Our knowledge of Welsh plant names is not sufficient to enable us to identify "Aule major" or "Father Before Son," and none of the dictionaries of plant names that have a place on our bookshelves afford us any assistance. "Jacob's Ladder" is, of course, *Polemonium coeruleum*, and "Noah's Ark" is *Cypripedium pubescens*.—(Gardeners' Magazine.)

— **PEAR BLOOM.**—There is every promise of a wonderful bloom on Pear trees shortly. I could wish it were not quite so abundant, and that the buds were rather less precocious. I do not think the organs of fertility in Pear blossom, or, indeed, in any fruits, are helped by slow expansion. Too often a long cold dull spell of weather, which keeps the buds in check, is inimical to fertility. It is intensely disappointing to see trees literally masses of blossom and then a few days later it has all disappeared, and a very poor set of fruits left behind. Does so great an abundance of bloom by so far exhausting the tree—for bloom expansion usually precedes leaf expansion—so far exhaust the trees that pollen grains lack the elements of fertility? It would be a capital plan were those who have numerous Pear trees that are so abundantly set with blossom buds to cut off one-half of the clusters, leaving the spurs, to see what was the ultimate effect on the cropping of the trees as compared with others of similar varieties not so thinned. According to present appearances the bulk of the trees should be masses of snowy whiteness by the end of the month. That is too early, and there would be more hope for a good set a fortnight later. However, in such case it is not possible for us to set back the course of Nature, though by the aid of some dull cold weather Nature may do it herself. We have had three or four very sharp white frosts, but some of the day hours have been warm.—A. D.

— **CHELSEA PHYSIC GARDEN.**—The suggestion that the Chelsea Vestry should apply to Lord Cadogan to have conveyed to them the old Chelsea Physic Garden on the Embankment, near Cheyne Walk, in commemoration of the Diamond Jubilee, seems to offer a faint hope of a satisfactory termination of a long-standing agitation; but unfortunately the matter does not rest with Lord Cadogan, but with the Apothecaries' Company. The case affords a striking example of how the objects of the pious founder may be frustrated, and mischief done where good was intended. The garden was conveyed in 1721 by Sir Hans Sloane, then Lord of the Manor of Chelsea, to the Apothecaries' Company by deed of gift, on condition that it should at all times be continued as a physic garden for "the manifestation of the power, and wisdom, and goodness of God in creation, and that the apprentices might learn to distinguish good and useful plants from hurtful ones." But the Royal Botanic Garden, as it is officially called, is now surrounded by houses, and is really no use for these purposes; and though there is a greenhouse and a medical library there, the growing of medical herbs has come to be a mere formal compliance with the terms of the gift. Science would certainly lose little by converting this quaintly pretty spot, with its statue of the worthy Sir Hans, and its magnificent old Cedars of Lebanon, into a pleasure garden open to the public. At present it is hidden from sight on one side by a high and particularly ugly brick wall, and on the other can only be dimly discerned through a close set iron railing.—("Daily News.")

— **NITRATE OF POTASH.**—Nitrate of potash accumulates in valuable quantities in the organically rich alluvial plains of India and China, the nitrate rising to the surface with the moisture by capillary attraction in the hot dry season. There have been discoveries made lately in South Africa of nitrate deposits of a high degree of purity, and said to be in enormous quantities, derived from the direct putrefaction of animal excreta.

— **BIRMINGHAM GARDENERS' ASSOCIATION.**—A very interesting paper on "Hardwooded Plants" was read by Mr. Walter Jones, gardener to Thos. Gladstone, Esq., Edgbaston, on the 29th ult., before an appreciative assembly of the members. The essayist is a well-known old local exhibitor of stove and greenhouse plants. The subject, which was treated in an excellent manner, was followed by an interesting discussion.

— **BAKED BANANAS.**—South Americans say baked Bananas are an excellent substitute for meat. They travel, fish, and hunt solely upon a Banana diet. For those weary of meat or unable to eat it (during the warm weather nearly all of us would gladly do without it) it would be well to try the baked Banana. Each end should be cut off, the jackets being left on, after the fruit is washed. From twenty to thirty minutes are needed for baking. They are placed upon the table, and one served to each person, instead of his usual piece of roast or fowl. They should then be slit lengthwise and buttered; the butter greatly improves the flavour.

— **NITRAGEN.**—Prof. W. Somerville has carried out a series of comparative experiments to test the value of the pure cultures of the several varieties of bacteria that inhabit the roots of our more important Papilionaceous plants, now sold under the head of "nitrogen." The investigation was described before the Botanical Society of Edinburgh on January 14th. Experiments were made with Peas, Broad Beans, Lucerne, and broad Red Clover. Only in the case of the Peas did the application of nitrogen result in an increase in the yield, and even then the variations in the weights of produce were too small to make it possible to say definitely that the inoculating substance affected growth either one way or another. The experiments were carried out in a garden attached to the Durham College of Science, in which it may be assumed that Peas and Beans have frequently been cultivated during recent years. As the soil was thus well supplied with the bacteria that associate with the roots of these plants, Prof. Somerville agrees that it is not surprising that the application of a pure culture of these bacteria should have been inoperative. But as regards Red Clover and Lucerne, neither of these plants has ever been cultivated in the garden, and the probability is that not a single plant of Lucerne ever grew in the garden, or, indeed, in any fields in the neighbourhood. The conditions, therefore, were to be regarded as distinctly favourable for exhibiting the action of the specific bacteria of these plants, and yet they failed to produce any effect. Apparently some improvements are required in the methods of manufacture or application in order to make nitrogen of service in agriculture and horticulture.—("Nature.")

LINES ON READING A SEED LIST.

Let others sing the Lily and the Rose,
Or scented secret of the Violet praise,
To me the meanest Broccoli that blows
Is more deserving of a laureate's lays.
And I would sing the Celery's stately ways,
The mysteries of Chili and Cardoon,
With laud of Leek and Lettuce fill my days,
And sing the Mushroom to the mild May moon.

What is a flower, when all is said and done?
'Tis, to the eye of sanity, a weed.
Look rather kindly, fructifying sun,
On my Savoy and Scorzonera seed!
O mother Earth, from thy rich bosom feed
My Parsley and my Parsnips and my Peas,
To glorious growth my Gourds and Marrows lead,
And my Shallots shall breath your eulogies.

Who sings of flowers? Mesembryanthemum
Shall pale before the Radishes I sow!
Cilanthus, Coleus, and Chrysanthemum—
My Cucumbers shall shame them at the show.
Kohl Rabi, sprout! Endive and Egg Plant, grow!
Thus watered by a poet's lyric tear,
And let the haughty horticulturist know
The kitchen garden is the Muse's sphere!

—("Pall Mall Gazette.")

HYBRID NARCISSI.

YEAR by year the number of Narcissi is being increased by a few cultivators who spend much time and trouble in the work of hybridisation. One of those whose efforts have been crowned with some truly remarkable results is the Rev. G. H. Engleheart. This worker has already in previous years given us many of great excellence, but crowned all his efforts so far by the exhibition on Tuesday, March 23rd, at the Drill Hall of two varieties named respectively Southern Star and Ellen Willmott. The first named belongs to the small cupped (*parvicoronati*) section, and is really superb. The perianth segments are broad, stout, and white in colour. But the chief feature in the flower is the cup, which is singularly broad and spreading, while the colour is bright orange red, becoming richer as it approaches the slightly fringed margin. The woodcut (fig. 60) depicts this gem amongst Narcissi. Ellen Willmott, of which fig. 61 is a representation, is a massive bicolor that can be placed second to none, even in this section of beauties. The blooms are large, bold, and wonderfully telling, standing up in a most desirable manner. The perianth segments are pure white in colour, broad, and of remarkable substance. The trumpet is of the brightest gold. The Narcissus Committee of the Royal Horticultural Society awarded each of the varieties figured a first-class certificate.

BEDDING
CALCEOLARIAS.

How disappointing it is to have gaps made in flower beds when they should be at their best, by that mysterious "going off" so prevalent among Calceolarias. Under the best of management a few plants will occasionally succumb, but the losses may be reduced to a minimum if the plants are properly prepared and planted in their summer quarters at the end of April or early in May.

Too often, I fear, the plants are left in their winter quarters till bedding out time arrives, instead of being transplanted in March. There is also a great tendency to unduly coddle Calceolarias, and in following such a course the cultivator takes a great amount of trouble, which might with advantage to the plants be dispensed with. At the present time we have about a thousand well rooted plants in frames, and before these lines appear in print I hope to have them all transplanted into beds 4 feet wide. The soil is already manured and dug, and the outline of the beds bounded by strips of board 10 inches in width, which are fastened to upright stakes driven into the ground. The plants will be lifted with nice balls of earth and planted 5 inches apart, the soil being pressed firmly around the roots as the work proceeds. If old lights were available these would be placed over the beds for a time, but as they are not at command strips of wood will be laid across the boards forming the edge of the beds, and these covered with garden mats. These mats will not be removed for a few days should the weather prove bright or windy; after that time they will be taken off each morning and put on again at night. When cutting winds prevail during the day the mats will not be removed, and by the beginning of April the night covering will be dispensed with unless a sharp frost seems likely to occur. A few degrees will not injure Calceolarias when properly hardened. I have followed this practice for several years, and have found it to answer well in every way.

When it is not easy to obtain boards to form sides for the beds a trench should be taken out 6 inches in depth, and the soil thrown up on either side. This will be found to give good shelter and plenty of head room for the plants. After levelling the ridges and beating with the back of a spade all is ready for planting and covering by means of cross stakes and mats. Plants grown under conditions above described are sturdy and hardy, will bear with impunity cold and frost severe enough to seriously cripple others that have been

coddled or grown too closely together. The former may therefore with safety be planted in their summer quarters at the time named, as it is important to get the plants thoroughly established before the drought of summer begins.

I have several times planted out Calceolarias during the last week in April, and these have more than once withstood 10° of frost without the slightest protection. All who have experienced a difficulty in getting good beds of Calceolarias I strongly advise to try the plan above detailed.—FLOWER GARDENER.

PLANTING OUT SHRUBBY CALCEOLARIAS.

THE half-hardy shrubby Calceolaria is not, perhaps, quite so popular for decoration in the flower garden as formerly. In its season of the first flush of blooming it is most attractive and showy, and merits a place on a border or in a bed where the plants can be massed together to give a decided tone of colour. A mass of Calceolarias when in good health and full of bloom never fail to elicit admiration. Although numerous other plants now compete with them in attractiveness, and probably surpass them in usefulness, yet yellow and brown Calceolarias still occupy a place in popular regard. It is true that the flowers are not the best for cutting purposes, as they soon drop. Hence their usefulness lies in affording a display upon the plants.

The treatment of Calceolarias is simple enough, providing the details are carried out at the right moment. It is quite wrong to allow the plants to stay in the cutting beds until late in May or into June. They become in these positions attenuated and unable to reveal their true character, which is, under suitable conditions, sturdy and shrubby.

In order to do justice to Calceolarias there are several methods of treatment applicable now, one of which should be adopted so as to secure good results in the culture of these plants. It will be evident to all who have safely wintered a number of cuttings in a frame, that the plants now need more room. Some time ago they commenced to form roots freely, and shortly afterwards to extend the stems, forming fresh foliage. As soon as this was apparent the growing points were nipped out, which has caused several shoots to form and grow simultaneously. All this has been done under airy conditions—that is, the plants have had a constant circulation of fresh air about them, with full exposure whenever frost was not

present or expected. Under any other conditions the growth would have been tender and elongated.

Methods frequently adopted are to lift each plant separately, transplanting in frames wider apart, or to place them in 5 or 6-inch pots. The best method, however, is to lift and plant at once in their flowering positions. At no time will they lift and plant better. They have time to become thoroughly well established while making slow and steady growth, which is essential to a bold, sturdy, floriferous habit.

The ground for their reception should be moderately rich and not too light. An application of decayed manure and a little leaf soil will give something for the roots to lay hold upon, and assist in retaining moisture in the soil, which is as essential as any food the manure supplies; in fact food supplies from any source are not available without a due supply of moisture in the soil. Incorporate the soil and materials added well together.

If the ground were well manured in the autumn, or for a non-exhausting previous crop, no manure will be necessary, but the ground may be well broken up, inasmuch as the planting can be better carried out. Eight to 12 inches of space may be given to each plant. The latter ought to be raised from their position in the frame with as much soil adhering to them as possible. Place in holes sufficiently large, and sink them a little lower in the soil than they were previously, so that the roots near the surface may have something fresh to work in and feed upon. Watering is scarcely needed, but should the soil in which the plants were previously growing be dry, a thoroughly good soaking should be given before lifting.—E. D. S.

FIG. 60.—NARCISSUS SOUTHERN STAR.

KITCHEN GARDEN NOTES.

WORK in the kitchen garden has during the present year been performed under exceptional difficulties. Continual rains and an absence of sunshine has thrown out of order the regular working of the soil and sowing of crops. The consequence is, that although vegetation generally is in a somewhat forward stage, kitchen garden operations are in a backward state.

A welcome change in the weather has apparently arrived at last, and all good cultivators know that it is now necessary to use every effort to bring up as far as possible arrears of work, so that crops may become fairly established before the drought of summer comes. In many instances, I fear, the sowing of the main crop of Onions has yet to be made, and numerous complaints of the ravages of maggot may, under the circumstances, be looked for later on. Much, however, may be done in the way of preparing for the attack of this insidious foe by dressing the soil heavily with soot as the seed bed is prepared, and by scattering dry wood ashes along the drills before sowing the seed. Another dusting of soot ought also to be given on a showery day, as soon as the young plants are well above the soil. Trivial as these matters may appear they are factors in cultivation which ought not to be neglected by those whose aim is to "deserve success."

The main crop of Carrots should now be sown as soon as possible, for there is always the danger of an attack of grub to be feared when late sowing is practised. A plentiful supply of dry wood ashes placed in the drills before sowing is the best precautionary measure to take that I am acquainted with. It is a plan I have often recommended in cases where grub has been troublesome, and its adoption has invariably been attended with satisfactory results. It is, perhaps, difficult to advance a convincing reason why this is so, but my opinion is that the minute particles of wood ashes favour rapid germination and root production; the young seedlings, therefore, become firmly established before dry weather sets in, and it is usually during dry summers that grub is so destructive.

Those who were fortunate enough to sow early Peas and Spinach during the few fine days that prevailed during the last week in February have cause to congratulate themselves, as both have made good progress; for notwithstanding the many wet days we have experienced since the soil has not been particularly cold, and later sowings will not, as in some previous years, overtake crops sown several weeks earlier. Cabbage plants, as a rule, are very backward this season, owing, no doubt, to the long spell of cold and wet during August and September last. This checked the young plants so much that in many instances they were not large enough to plant in their permanent quarters at the usual time, and those who left them to winter on the warm borders where they were pricked out will this year have the advantage in point of earliness over others who followed the usual course.

The time has, however, now arrived when plants in all stages may by taking a little extra trouble be considerably hastened towards maturity. On bright days the hoe should be kept going among them; the warm air will then penetrate the loosened soil, sweeten and enrich it, and by so doing start into activity innumerable thread-like roots. Those who are yet sceptical as to the possibility of forwarding crops by these means should remain in doubt no longer, but test the matter for themselves. Let the hoe be run through half their Cabbage bed twice weekly, while the other half is left untouched, and I shall be much surprised if they need further proof of the correctness of this scientific principle. A little later on when the plants are growing freely a small quantity of nitrate of soda should be sprinkled between the rows, choosing a showery day for the purpose.

Lettuces have not wintered well with us, and excepting a few dozens of plants grown in a very warm position, our spring-sown plants seem likely to overtake those sown in August last. Golden Queen and Early Paris Market are a pair very hard to beat in point of earliness and good quality.

Asparagus Kale is at the present time affording a plentiful supply of greens of the choicest description—indeed, there is nothing among Borecoles to surpass it during March and April. This should be borne in mind and acted upon, now that the time for seed sowing has arrived. The next few weeks will be extremely busy ones to kitchen gardeners and allotment holders, as the work of sowing and planting must perforce be pushed on with all possible speed, for when the performance of these operations is too long delayed, scanty or diseased crops are often the result, and general work is kept in arrears throughout the summer. The good cultivator therefore realises that the present moment calls for an extra effort on his part in the endeavour to derive a full share of benefit from Nature's storehouse, the soil.—KITCHEN GARDENER.

PEACHES AND NECTARINES.

It is well known that thinning the fruits has for its object the production of flesh with a minimum of skin and stone. This requires early attention to attain the end in view, especially where the fruits are

too thickly set, removing those that are badly placed first, and performing this often-neglected operation gradually. It is well, however, to let the fruit attain the size of horse beans before removing any but the very small, and in thinning the others remove those at the back or under side of the trellis, leaving the best placed for receiving light, three to five being retained on a last year's shoot, to be reduced to two or three when the size of marbles, and when not larger than Walnuts to two on strong shoots and one on weaker, always retaining a few over the number required for the crop to meet casualties in stoning. Likewise have regard to the vigour of the trees and the relative size of the different varieties, weakly trees being more severely thinned in the fruits than those which are vigorous, and the large-fruited varieties more than the medium-sized.

Disbudding is a very unnatural but essential process in cultivation. It should be commenced early and followed up at short intervals until no more shoots are left than are necessary for bearing another season, attracting the sap to the fruit, and for furnishing and extending the tree. This means a shoot being left at the base of each bearing one to take its place after fruiting and cutting out, training in its full length, or if likely to become too long stopping at about 14 inches. Then a shoot must be retained on a level

with or above the fruit, and this stopped at the third leaf, all laterals in either case being pinched at the first and to one afterwards as made. Extensions of last year's shoots should be left at about 15 inches distance to form bearing wood, and the extremity growths taken forward, laying in shoots where required for furnishing the trellis early in every part with branches and bearing wood on them in due course, avoiding overcrowding.

Of insects the most troublesome next to red spider are aphides. Fumigation with various preparations of tobacco, self acting or otherwise, and vaporisation with nicotine essence, are still the best means of destroying aphides under glass. But both fumigating and vaporisation must be practised very carefully in Peach houses with trees in tender leaf, indeed at all times with the fruit, from setting to stoning, always having the foliage dry, and taking special precaution against an overdose by moderate application, repeating if necessary at short intervals, or on consecutive evenings to effect a clearance with safety. When an overdose is given the leaves are scorched, and the damaged parts shrivel and fall off, thus giving the trees the appearance of having had the foliage eaten by insects. Tobacco water leaves a stain on the fruit, which may or may not disappear with subsequent syringing. It acts very effectively against all the race of aphides, and a pint of strong tobacco juice to 3 gallons of water serves as a preventive and remedy. The various advertised insecticides serve equally well, and in some cases better than home-made ones, always being careful to follow the instructions.

FIG. 61.—NARCISSUS ELLEN WILLMOTT.

Brown aphides are more difficult to kill than green fly, as they have such shining bodies, and hug the twigs so tightly as to throw off solutions intended for their destruction, but the narcotic properties of tobacco overcome the pests. This can be applied with a brush, or rub the infested parts gently with the fingers frequently dipped in the liquid, then followed with the tobacco water by means of a syringe to make sure of stragglers. Timely attention, however, to first attacks of these pests on the shoots often saves a whole house.

Soapy solutions are potent for the prevention and destruction of red spider, but prevention is better than remedy, and a few are easier killed than a great number. To prevent or destroy aphides, red spider and mildew at one application, a somewhat strong decoction of quassia chips and solution of softsoap may be used, 4 czs. of quassia chips being steeped overnight in a gallon of rain water, then boiled a quarter of an hour, adding to it as it cools 4 czs. of softsoap, straining and applying to shoots infested with brown aphides by means of a brush, or dipping them in the mixture, and rubbing gently with the fingers. The material is sooner applied with a syringe, and better with a spraying nozzle than through a rose; but I find it best to go over the trees in the manner indicated, and having dressed the worst parts spray the trees thoroughly, syringing the following day with clear water. If repeated twice or thrice the black and brown aphides are got rid of, but it is not necessary or desirable to use the mixture so strong for aphides and red spider, as it is safer and quite efficacious at half strength, having two gallons of water instead of one.

—GROWER.

SEASONABLE HINTS ON FLORISTS' FLOWERS.

AFTER a long period of wet and stormy weather there seems to be some prospect of a change, which will be especially grateful both to farmers and gardeners, and the cultivators of florists' flowers are beginning to hold their heads up. A busy time is before us, for the broken weather has greatly retarded both farming and gardening operations. It has been difficult to snatch a time for planting the *Ranunculus*, and one is only waiting now for a few dry days in order to plant *Gladiolus*, so let us see what is to be done with our favourites.

AURICULAS.

Where drip has been successfully excluded these delightful spring flowers have a most flourishing appearance; the mild winter has been in their favour, and although I do not think they are particularly early, it seems as if we are on the point of having a good bloom. As the practice of top-dressing has been to a great extent abandoned, there is little to be done now except to watch the development of the trusses. Where it is wished to have a thoroughly well-proportioned truss, scissors must be carefully used to get rid of some of the pips when they are too much crowded, and as the plants are now growing rapidly they will require frequent watering. Wherever it is possible rain water should be used. There ought to be no difficulty about that, as in the four months of this year we have had more than 8 inches.

It would be well in a little while, when the pips begin to colour, to screen the plants from too much sun. While in all other classes of flowers new varieties are pushing the older ones out, the Auricula is still very chary of admitting new varieties into its ranks. Thus, for instance, our great northern champion exhibited a stand of twelve at the last spring show of the Southern National Auricula Society, of which eleven, I believe, were new ones raised by himself and friends, and yet of these only one was in commerce, and probably this the least desirable of the lot. We go to the exhibition, admire the new seedlings, but alas! it is admiring them at a distance; the hope of obtaining them is but a shadowy one, and very often some of those which gave promise in their youth fail to fulfil that promise as time goes on. The date for the Southern show is fixed very early this year; but one can only hope the fine weather we are now experiencing may bring the plants on in time for it.

CARNATIONS AND PICOTEEES.

It has been a curious season for these plants, at least last autumn was most unfavourable for the rooting of the layers. One of our largest growers for sale told me he had never had so many badly rooted ones; in many cases the layers were left on the plants in the hope that in the early spring they might somewhat recover themselves. I have just planted out my own beds, and the plants in the main were fairly well rooted; they had been in pots in the frames during the winter, and were singularly free from spot and aphides. They were, however, most of them from seedling plants, and were consequently border varieties.

GLADIOLUS.

The very wet condition of the soil has greatly hindered the planting of these bulbs, but if we have a continuance for a few days of fine weather I shall soon be busy about mine. In planting them it is well to give them plenty of room, and to see that they are firmly planted. A little very coarse sand or road grit may be placed about them, but I do not care for fine sand, as it becomes too close, and does not give the roots that freedom of action which they like to have; and I think that the distances which I have always given—that is, of rows 12 inches apart, and the roots about 9 inches apart in the rows, and about 4 or 5 inches deep—cannot be improved upon. I have said nothing about preparation of the beds, because I gave directions for that in the autumn, and it is too late now to apply any manure. I find there is still a good deal of confusion in people's minds about the *Gladiolus*. Some tell me, "Oh! we do very well with them;" but when I come to

inquire I find that the sorts grown are either *Brenchleyensis* or some of the *Lemoine's* section, which are certainly more easily grown, and not subject to the disease which is so fatal in most gardens to the hybrid *Gandavensis* section. However much people may admire this section the number of those amateurs who grow it to any extent rather diminishes than increases.

PANSIES.

I have, alas! little to say on the subject of these flowers. The drought in the early part of last year was fatal so far as my own small collection was concerned. It is one of those florist flowers which do not flourish in the South of England, and when one recollects how grandly they grow in Scotland and the North of England, I cannot but feel that it is growing them under difficulties here. As far as the winter is concerned they would probably have done very well in beds, but I have not ventured upon that method of growing them for years, as they used to get so eaten off with snails and slugs. By-the-by, has anyone noticed that notwithstanding the wet and mild winter how few of these pests of the garden there are about? People have a notion that a hard winter destroys these, and that a mild one tends to their increase.

I believe the reverse of this is the truth, and for this reason—in a mild winter they keep nearer on the surface, and consequently become an easy prey to blackbirds, thrushes, and starlings, which are always on the look out for them. In a hard winter, on the other hand, when the ground becomes frozen, they have no difficulty in getting down out of its reach, and the harder the frost the deeper they go, and then when the thaw comes they emerge from their hiding places, and after their long fast are ready to devour anything that comes in their way. Where Pansies are grown in pots they will require some attention now to be transferred to larger pots, and where the shoots are long small sticks should be placed to them to keep them upright; these sticks must be very slight not to spoil the appearance of the plants.

ROSES.

The winter has been a most favourable one for this queen of the garden. There has been no frost to injure them, and from all parts of the country I daily receive letters saying how well Roses are looking. Pruning will now, of course, be in full swing; it is really on the tyro who requires instruction on this point. Hybrid Perpetuals may now be pruned, and where the plants are strong growers they require less pruning than when they are weaker; in fact, the weaker the plant the harder it must be cut, and where Roses have been planted during the past autumn they must be cut hard. Teas may, of course, be left until next month. They also look well, but we must recollect that we are not out of the wood yet; we have to go through the Blackthorn winter, and the delightful weather of the past few days must not make us forget this, or that we have those terrible May frosts to dread. It may be that we may escape them, but past experience makes it doubtful.—D., Deal.

BEGONIA GLOIRE DE SCEAUX.

OF the winter-flowering section of Begonias this is decidedly one of the best and most useful, and deserves to be extensively grown in every garden where a supply of bloom is desired through the dull months of winter and early spring. With me it commenced flowering towards the end of December, and from the middle of January to the beginning of the present month it was a mass of bloom, almost entirely covering the foliage. When it would have finished blooming I cannot say, for at the last named date the flowers were removed to encourage fresh growth for propagating, as I wish to obtain as large a stock as possible. At that time it showed not the least inclination to terminate its season of flowering, and, even if no more buds had been produced, it must have continued to the end of this month, probably much longer.

The plant possesses a sturdy, upright, and compact habit of growth, and branches freely at every joint until it shows its first buds; after that it is covered with flowers. I have only one plant, but was evidently fortunate enough to hit upon the exact mode of culture it likes, and I append a few particulars of the treatment, as they may be of service to other amateurs who are growing this Begonia.

The cutting, a very small one, was obtained on April 17th of last year, and was inserted in a 2-inch pot in a propagating case in a greenhouse. When rooted through to the sides of the pot I removed the plant to a light but shaded position on a shelf near the glass at the back of my stove, where it soon commenced growing freely, but, having taken so long to root, did not require potting until the middle of July, when it was shifted into a 3½-inch pot and returned to the same quarters. On September 24th it was again shifted, this time into a 5½-inch pot, which size would be found very suitable for most purposes, and the plants can be conveniently accommodated on a shelf near the glass better than if in larger pots.

When at its best the plant was more than 2 feet high and 15 inches through at the base, forming a small pyramid-shaped mass of bright rosy flowers, which contrast admirably with the bronzy green cordate leaves of this variety.

The soil used consisted of two parts peat, two parts loam, one part leaf soil, with a fair addition of charcoal broken small, and sand. The temperature ranged from 65° to 70° at night, with a rise of 5° or 10° by day during the early stages of its growth, gradually falling to 60° at night, with a proportionate rise by day in November and December.—C. L. B.

ROSE SHOW FIXTURES FOR 1897.

- June 17th (Thursday).—Colchester and Ryde.
 „ 18th (Friday).—Portsmouth (N.R.S.).
 „ 26th (Saturday).—Windsor.
 „ 29th (Tuesday).—Canterbury, Sutton, and Westminster (R.H.S.).
 „ 30th (Wednesday).—Croydon.
 July 2nd (Friday).—Crystal Palace (N.R.S.).
 „ 7th (Wednesday).—Glasgow and Reigate.
 „ 8th (Thursday).—Bath, Gloucester, and Woodbridge.
 „ 15th (Thursday).—Norwich (N.R.S.) and Helensburgh.
 „ 22nd (Thursday).—Halifax and Trentham.
 „ 27th (Tuesday).—Tibshelf.

The above are the only dates definitely fixed that have as yet reached me. I shall be glad to insert in the next list, which will be issued about the middle of April, any further fixtures that may be sent me.—
 EDWARD MAWLEY, Rosebank, Berkhamsted, Herts.

N.R.S. SOUTHERN SHOW.

LOCAL considerations having rendered any day in the Diamond Jubilee week impracticable, the date of the National Rose Society's Southern Show at Portsmouth has been changed from Wednesday, June 23rd, to Friday, June 18th.

ROSE BUDDING IN FEBRUARY.

I OFTEN get letters with questions on Rose culture, which I answer to the best of my ability; and I think the subject matter of one lately received is worthy of record. I was asked when it would be advisable to cut back the laterals of stocks budded last month (February). Budding under glass being rather unusual, as grafting is the mode generally adopted, I asked for more particulars. My correspondent—Lady Fawen of Bealings House, near Woodbridge—then informed me, to my astonishment, that the budding was done out of doors, and appeared to be quite successful. She received some Marie Van Houtte Roses by post from Nice. Though four days en route they arrived in such good condition, with such nice plump buds for working, that she was tempted to try them. Some old standard stocks were soon discovered in an orchard which were not utilised last summer, and had last year's laterals still remaining, and just (but, of course, only just, as it was February 16th) commencing to grow afresh. The bark did not rise very well, but the buds were put in, and would I come and satisfy myself as to their being thoroughly alive?

I would, and I did, on March 24th, five weeks after the budding. As far as I could see every bud had taken, most of them had swelled, two had actually commenced to grow, and the cuts were healed. I could only say I wished that every one of my Tea buds, put in last July, looked as well.

I was also shown some Scarlet Thorns which were budded instead of grafted in March on White Thorn some years ago; they were nice young trees, and the unions appeared perfectly sound. This last success—sound unions—may yet prove not to have taken place with the Tea Roses, but after all there does not seem any reason why budding should not be successful on old wood at any time as long as the sap is in full motion, and no check takes place.

The experiment has at all events been successful at present. I should not recommend it as a rule without further test, and I fancy Tea Roses have never been budded out of doors in Suffolk in the middle of February before.—W. R. RAILLEM.

ROYAL HORTICULTURAL SOCIETY.

MARCH 23RD.

SCIENTIFIC COMMITTEE.—Present: Rev. W. Dod (in the chair); Mr. Douglas, Mr. Michael, Dr. Müller, Rev. W. Wilks, Dr. Bonavia, and Rev. G. Henslow (Hon. Sec.).

Bulbs with Arrested Roots.—With reference to the samples sent to the last meeting by Mr. Atkinson, Mr. Douglas was of opinion that the treatment had perhaps not been quite advisable, for he thought that they should have been put out of doors, and not in a shed, and covered with 6 inches of cocoa-nut fibre. If, however, there was something deleterious in the compost sent for inspection, this could be at once ascertained by analysis. Such, however, would be beyond the province of the Society.

Wireworms among Carnations.—Mr. Weguelin of Torquay asks for remedies against this trouble. The suggestions of linseed cake, carrot, scooped out potatoes, as for slugs, &c., were made, but it would appear that in the present case they are too numerous for such traps, as indeed the writer admits. Gas lime was recommended as the only very efficient remedy, but it might injure the Carnations. The land having been well dressed with lime or soot shows that these ingredients are quite insufficient, though gas lime would probably have been effective.

Carnation Leaves Diseased.—Mr. Fagents of Honey Pots, Westfield,

Woking, sent some leaves with peculiar red streaks upon them. They were forwarded to Kew for further investigation.

Germination of Mushrooms.—Inquiries were made by Mr. Baker of Cobham Park as to somewhat contradictory statements in books upon this subject, as in Mr. J. Wright's "Primer of Horticulture" it is stated that it has been observed, whereas in Dr. Scott's "Flowerless Plants" (page 268), it appears to have never been seen. Mr. W. G. Smith, having been appealed to by the Secretary for his opinion, writes as follows:—"I have many times seen the spores of the Mushroom and its allies germinating. With me they have often quickly germinated on glass, and more often on moist blotting paper. The fungi must be allowed to shed their ripe spores on to the moist paper. After a day or two a damp microscopic slide must be placed upon the part of the damp paper where the spores have fallen, and it will often happen that some will be found to have germinated. I have seen the germinating examples whilst drawing the spores with a camera lucida. . . . Messrs. Wood of Wood Green managed to get spawn of the Morel (from material sent by me) to germinate and form spawn. I once exhibited before the R.H.S. examples of *Coprinus atramentarius* raised by me from spores. This species can be easily raised (and it is not very far removed from the Mushroom) from spore to perfect fungus. The time it takes is three months. I believe some of the French manufacturers of Mushroom spawn have raised Mushrooms direct from the spores. The spores of some of the allies of the Mushroom germinate readily in expressed juice of horse dung. I have many times seen them, and am not the only person who has seen them on glass."

Trametes radiceperda, Hartig.—Dr. Plowright sent a specimen of this fungus "to illustrate the mode in which it develops its hymenophore upon the roots of an affected Scotch Fir. The hymenium is resupinate. The fungus finds an entrance into the roots of living Fir trees by the extremities of the mycelian hyphae insinuating themselves between the bark scales. It rapidly extends between the living bark and wood, and soon reaches the wood itself, which it at once destroys. The mycelium can travel in the ground from tree to tree."

Barley-smut.—Dr. Plowright also sent the following communication upon the injurious effect of this fungus upon the colour of the crop. "It is only a few years ago—a very few when one looks back upon it—that our attention was drawn by Mr. J. L. Jensen of Copenhagen to the fact that there are two distinct kinds of smut upon Barley. At first there was a considerable disinclination to regard these two smuts as being due to two distinct species of *Ustilago*; but since they are not only easily distinguishable by the unaided eye, but also differ in the size and form of their spores, and as the latter have been found to germinate in a totally distinct manner, there is now no doubt about it. Our American confrères at the time repeated the protective measures suggested by Mr. Jensen, and confirmed their efficacy; but here the matter stopped, for the simple reason that the damage done by smut was trivial, and from a monetary point of view the dressing of seed Barley was a needless expense. A few days ago a circumstance came under my notice which materially alters the complexion of the case. A gentleman who is rather an extensive grower of Barley in West Norfolk drew my attention to the fact that two years ago his Barley was of an excellent colour, while it was in the stack; but when it was threshed it was so discoloured that he had to accept a very low price indeed for it. He attributed the damage in colour to the number of smutted ears which remained intact when the crop was harvested, but which, by being broken up in the process of threshing, discoloured the whole sample, just in the same way as bunted Wheat does. Fortunately he had kept some of this discoloured Barley. On inspection it looks as if it had been damaged by exposure to the weather. When a little of it, however, is shaken in a test tube with clean water the water becomes discoloured, and a drop placed under the microscope is seen to be full of *Ustilago* spores. So convinced was this gentleman of the cause of the discolouration that in the next season he dressed his seed Barley with the ordinary sulphate of copper dressing, which is used for seed Wheat for the prevention of bunt. The result was eminently satisfactory; for that year his crop was free from the disease, and the grain, of good colour, realised a proportionately good price. The ordinary *Ustilago carbo*, as it used to be called, has no detrimental effect on Barley, beyond destroying a certain percentage of plants, its spores being all blown away long before the harvest; but with the species in question, which, by the way, has received already a considerable number of names—Mr. Jensen originally called variety *tecta*—the ears retain their shape, the awns do not fall off, and the kernels are converted into solid compact masses of black spores; not so compact, however, as to withstand the concussion of the threshing machine without being disintegrated into fine powder, which becomes scattered over the healthy kernels." With this communication were received:—(1) Specimen of the compact form of Barley-smut, gathered on the 15th of last July, at which time the common Barley-smut had all disappeared from the field. (2) Three samples of Barley, two of which are discoloured by the smut, as may be shown by shaking them in water and examining the washings. (3) A sample of healthy Barley from which no spores could be washed."

A vote of thanks was unanimously given to Dr. Plowright for his interesting communications.

Portugal Laurel with Defective Foliage.—Rev. W. Wilks showed branches, one healthy for comparison, the other showing a silvery appearance. It is a well-known case, and apparently attributable to defective nutrition. The peculiarity resides in the fact that the upper epidermis becomes detached, and the presence of air gives the whitish appearance. The palisade tissue also separates readily from the mesophyll, and its cells are easily broken asunder. There is no trace of

fungi or other organism. Mr. Henslow observed that a tree in his garden exhibited the same appearance and died. Its roots were found to have penetrated pure gravel.

ROYAL HORTICULTURAL SOCIETY'S COMMITTEES' AWARDS.

YOUR correspondent of last week, "F. R. H. S.," is still unsatisfied with me, although he greatly qualifies his criticisms now. In one case he seeks to charge me with inconsistency, because I am represented to have written that I do not think the present too free making of awards *should* be restricted in the least. I did not write *should*, which would have been absurd. I wrote *would*, which alters the complexion of my assertion entirely.

Putting the Chiswick or Drill Hall meetings in comparison with the Chester and York Shows is ridiculous, and has nothing to do with the matter. My previous reply related to a statement of "F. R. H. S." that awards were relatively far more liberally made at the Temple Show than the Council made them at Chester or York. I showed wherein laid the distinction, the former being a show without prizes, while the two latter were essentially competitive shows. What on earth has the Drill Hall or Chiswick meetings to do with this comparison?—A. D.

NOTES ON VINES.

THE preparation of Vines in pots for early forcing is an operation that requires a fair amount of attention. Cut-backs of last year's raising are the best for making sturdy canes and perfecting the growth early and well. The cut-back has the advantage of a number of roots to begin with, and if grown well in the previous season so as to have short-jointed and stout canes about 4 feet in length, and not given larger pots than 6, or at most 7-inch, they will push strongly when cut down to one or two buds and placed in gentle heat in February. Such "cut-backs" will have much of the appearance shown in the illustration on page 213, March 24th, 1892, as regards the roots when turned out of the pot for the first repotting after the cane has made a little top growth, this not being more than 3 or 4 inches, and better less, as no roots will then have been made, and the soil being mostly removed no damage will be done. Straggling roots would then be shortened, and the Vine placed in a 7 or at most 8-inch pot. All that is necessary at the first potting is to provide fresh soil and get abundance of fibrous roots in it.

The Vines thus treated will now require their final potting—12-inch pots are a proper size. They should be clean and efficiently drained, potting firmly in turfy loam, with about a tenth of old mortar rubbish added. This will secure a good root formation, and any extra vigour desired can be promoted by top-dressings or liquid applications of chemical manures. Bottom heat is not necessary, but if the Vines are plunged in it for accelerating root action, it should not exceed 80° to 85°, and they must not remain in that so long that the roots enter the plunging material. The better plan is to place the pots on slates over the hot-water pipes, or in such position that the canes can be trained from the sides of the house beneath the roof, near the glass to insure the solidification of the growth.

The house should be kept rather close, and if the weather be bright shade for a few days. Syringe the Vines and otherwise damp the house, so as to secure a sturdy and clean growth. Pinch the laterals at the first joint, and subsequent growths treat similarly, stopping the leader at 6 to 8 feet, according to the length of cane desired. With proper attention the Vines will make canes like walking sticks with eyes like nuts by August, when they can be subjected to a ripening off régime, but not too suddenly, and they will be in proper trim for starting in November to afford ripe Grapes at the end of March or early in April.

Vines for planting are usually a very motley lot unless picked, and many of them as notable for the pooriness of the canes as the paucity of their roots. Albeit the pots they are in may not be much less in diameter than that usually given to fruiting canes, yet they turn out with scarcely any fibrous roots, and the amount seldom comes up to that shown outside the mass of fibrelets on the illustration above referred to. This exhibits a grand foundation of roots, abundance of fibres issuing from the base of the cane and plenty for laying in the soil, so that a good grip of the soil is had without loss of time. Indeed, it shows exactly the type a planting Vine should be, for in addition to the splendid root system there is the advantage of a stout stem with free channels for conveying the sap, and as such Vine is cut down for inside planting to a few buds near the soil it must make a sturdy growth if properly planted and attended to afterwards. It is alluded to for contrast with straw-like canes and the thin bare roots frequently comprising Vines for planting.

Planting is, perhaps, best done when the young growths have extended an inch or two, which, when the Vines have been kept cool, occurs early in April. Where provision has been made for inside and outside borders, the Vines should be planted in the former, confining the roots to it until they have well occupied the available space—in fact, a 4 to 6 feet width of border is sufficient in the first instance. The Vines should be shaken out and placed in position either before or after they have grown to the extent of a couple of inches, the roots being disentangled and spread out evenly in the border, covering them about 3 inches deep, and watering moderately to settle the soil about them.

Vines of the present year's raising will not require to be planted out for some time yet. They are preferably raised in squares of turf, and may be planted when the roots are protruding through the sides, or if in

pots they should be turned out before they become root-bound. They will require to have the temperature suitable to Vines in growth—namely, 65° at night, and 70° to 75° by day, with an advance of 10° to 15° with sun; but Vines of last year should be allowed to start unaided, syringing them two or three times a day, according to the weather.—G. ABBEY.

EARLY CINERARIAS.

ON page 251 "A." says, "Those who grow Cinerarias for very early blooming must largely force, and, of course, the plants are drawn and the blooms somewhat demoralised." This is misleading, as is well known to those who grow Cinerarias for early flowering. I have them in bloom fully a month before Christmas, which, I suppose, would be considered early, as the regular Cineraria season is not till March and April. I find Cinerarias most useful during December, January, and February, and make a special effort to have a good stock of them. I do not find that the plants are "drawn" at all, and certainly they are not forced. I grow Sutton's strain of Cinerarias, which are good in form and colour, while the habit of each plant is dwarf, but not too much so. Extreme dwarfness is a defect not to be encouraged, as such plants have a "dumpy" appearance.

For having Cinerarias in flower at Christmas, or earlier, the seed is sown during the early part of May. A long season of growth is thus afforded, which dispenses with any necessity for forcing the plants in strong heat. I make two sowings—one at the time named and another the first week in June. A regular succession of flowering plants is then assured, assuming, of course, neglect does not follow the initial stage. Any fine sandy sweet soil will suffice to sow the seed in, and well-drained pans are the best for the purpose, covering with a square of glass. To maintain the soil in a moist state a little moss over the glass will dispense with the necessity for shading the frame.

Directly the seedlings show through the soil we remove the moss, and tilt the glass on one side to admit air to keep the plants sturdy. A weakly growth cannot produce dwarf plants with robust foliage and strong heads of bloom, such as are required to be effective in a decorative point of view. The pots in which the plants are to flower range from 4½ inches to 7 inches in diameter. A compost largely composed of decayed leaves, loam, and sand suffices for the first potting. Afterwards more loam is added in the place of the leaves, with a small quantity of partly decayed horse droppings for the final shift. It is a mistake to allow the roots of Cinerarias to become matted together before they are repotted, the foliage becomes crippled, and the flower spikes are never so stiff as they ought to be; in fact, the plants always present a half-starved appearance.

The first sowing is made in a partly spent hotbed, the second in a cold frame behind a north wall. The latter affords the best site for the plants for the first four months of their growth, as the trouble of shading the frame can be dispensed with, which is a great saving of labour.

During the month of October frames or pits with a southern aspect suit the plants better, as here the growth becomes more matured than if the plants remained in their previous position, until finally removed under cover, as they must be before frost renders their removal imperative, as Cinerarias cannot withstand any frost.

For flowering the plants we erect a flat temporary stage in a large airy Peach house, which is kept as cool as possible. By the first week in November the bulk of the leaves have fallen from the trees, the Cinerarias then get plenty of light. At no time must the plants be crowded, and the leaves of one plant should only just touch those of its neighbour. Cinerarias are subject to attacks of green fly and a leaf-mining maggot, common to Celery. Frequent fumigations with tobacco smoke will rid the plants of the aphides, but hand-picking must be resorted to for ending the maggots.

Cinerarias must have abundance of water both at the roots and over their leaves during active growth, especially when the pots in which they are growing are small; stimulants frequently applied are a great aid to the plants, a little and often is the best course to pursue in feeding them. Liquid made from cow manure and soot is excellent for the purpose.—E. MOLYNEUX.

GOOD CINERARIAS.

I NOTED recently at Anningsley Park, Chertsey, an exceptionally fine strain of this useful winter and spring flowering plant. It is a selection that has been fixed by careful crossing during a considerable number of years by the gardener (Mr. Tomlin). Most colours general among Cinerarias are represented, but the indigo blue shades and self crimson and rosy hues appeared extra fine. Others with a broad white ring accompanied by various rich shades of colour were also most attractive.

The individual size of the flowers, too, was in many instances exceptional. I prefer a Cineraria pip a couple of inches or so across to one 3 inches in diameter. The latter lose that finish noted in the smaller kinds. But this is a matter of taste. Whilst improving the blossom Mr. Tomlin has had in view a not less desirable point—namely, a dwarf sturdy habit of growth.

Cultivation has, of course, much to do with the appearance of the foliage; but there is no mistaking the general sturdiness of leaf and the dwarfness of the plants in this instance. When a tolerably large greenhouse is filled with capital specimens of this nature such a collection is worth a passing notice.—H. S.

PLATYLOBIUM FORMOSUM.

LIKE many other hardwooded plants, the *Platylobiums* are not grown so extensively as they formerly were, notwithstanding their decorative merits. There, however, are several species well worthy of the attention of plant growers. When well grown *P. formosum* (fig. 62) is a most beautiful object, and will thrive well under the conditions generally assigned hardwooded plants. It is a free branching plant, and the stems are slightly hairy. The leaves are dark green above, paler below. The buds are deep crimson, and when expanded the back of the whole flower retains this colour, whilst the front side is rich orange yellow, saving a reniform belt of radiating crimson lines near the bottom of the standard. The flowers are produced during the summer.

PANSIES AND VIOLAS.

THE usefulness of Pansies and Violas for the decoration of beds and borders in spring and early summer is unquestioned. Lines of yellow, blue, and white Violas are very effective for the front rows of long borders, whether straight or curved. Plants, however, do not succeed well too near or under the branches of shrubs or trees, less because of the shaded position than to the absence of moisture in the soil, where the roots of vigorous shrubs and trees ramify and feed. It is, therefore, desirable to avoid all such unfavourable positions, choosing those which are, and will continue to be, moist, and open to frequent showers. For the same reason beds in dry poor soil, and extremely hot positions, should be avoided.

Pansies and Violas like a fairly rich and retentive soil, though one that admits of the free passage of water. Heavy soil may be well dug over and lightened with leaf soil, sand, or gritty material, containing no injurious substances. Wood ashes are an excellent addition to the soil for Pansies. As is well known, wood ashes are largely composed of mineral matter, chiefly potash. Light soils are frequently deficient in this, therefore their addition will be beneficial. The chief effect of wood ashes on heavy clayey soil will be in the mechanical effect they exert by accelerating the division of adhesive particles. Potash is naturally more abundant in heavy soil, and becomes more or less available for the wants of plants. Light soils may be further improved for Pansy culture by incorporating with them a fair quantity of well-decayed manure and leaf soil. The manure tends to hold the moisture in the soil, and with that appropriate food is readily available, while more can be obtained as required by the roots. Excess of organic matter must, however, be guarded against. Under very moist atmospheric conditions the growth which follows may be too luxuriant in foliage.

The positions intended for planting Pansies and Violas are best prepared in autumn, when the soil requires enriching with manure, and the planting deferred until spring. A further course of preparation may be adopted at the latter period, consisting of well forking over the soil, so as to make it workable for planting. It is assumed that when spring planting is carried out the plants are strong, sturdy specimens from cold frames, in which they were inserted as cuttings in the autumn. Such plants are usually freely furnished with healthy roots, having active fibres bristling all over them, hence the change to a new root run and more space is productive of rapid growth, as well as a floriferous habit.

While the plants are yet young they move readily. It is very desirable to plant early for other reasons. By removing them to their flowering quarters early in April they have time to become established in the soil before the hot weather arrives. Late planting is frequently the cause of unsatisfactory results following. Considerable care is needed in lifting and transferring them to the positions, care which is not always accorded. It is true Pansies and Violas are not so difficult as some plants to lift and replant even in May if the ground is moist and the plants not too large. The objection to allowing them to remain in the cutting beds is that they are liable to be spoiled in habit and flowering proclivities. Early planting induces the formation of bushy plants. The main stem is arrested in growth by the removal, and the fresh run for the roots gives an impetus to the production of numerous shoots from the base, which in due time flower freely.

Plant 10 inches to 1 foot apart. Sink the plants a little lower than they previously were. Keep the ground free from weeds, and occasionally stirred with the hoe. This allows warm air and moisture to enter, and is an important factor in promoting free growth. In dry weather a copious watering once a week will be beneficial, followed the next day by loosening the surface. Should the weather continue dry mulch between the plants with a mixture of decayed manure and leaf soil.

The flowering period may be prolonged by following the simple practice of cutting off the withered flowers, thus preventing the formation of seed pods. Beds of Pansies which have stood the winter unprotected require now some encouragement in order to assist growth. The whole of the space between the plants ought to be stirred, and a little soot dusted over. Work this in with the hoe, and on an early, warm, dry day give a copious watering of liquid manure made by pouring 30 gallons of water on a peck of cow or sheep manure. Frequently stir this for a week, then allow to settle, and give the clear liquid occasionally until the growth is free.

In choosing a position for planting Show and Fancy Pansies to afford blooms for exhibition, shade from the midday sun should if possible be

secured. The shade and shelter of a well-trimmed hedge is an admirable place. Except for the shade the position should be fully open to air and light, but the plants are best protected from the effects resulting from rough and windy quarters. Regular and systematic attention must be afforded to prevent the plants being crowded with growth or weeds. A loose surface ought to be kept, and the careful removal of flowers as they pass their best condition, only allowing one or two at a time to open on each shoot. The plants require to be fed with liquid or chemical manures about every ten days. Protect the best blooms when open from strong sun and heavy rain.

Violas are termed by some cultivators Tufted Pansies. This certainly describes the habit of growth of Violas generally, but it gives no idea of the differences which distinguish them from the Show and Fancy Pansies. The old term *Viola* has long been understood to mean a class of the order *Violaceæ*, having small self-coloured blooms with a distinct

FIG. 62.—PLATYLOBIUM FORMOSUM.

eye and light pencilled rays on some of the petals. Some, however, of the Violas have very large blooms, but the distinction from Pansies is usually evident.—E. D. S.

READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—The usual fortnightly meeting was held on Monday evening last, and was largely attended. The President, Mr. C. B. Stevens, occupied the chair. Apart from the lecture, the feature of the meeting was a presentation of a purse of gold and an album containing the names of 138 subscribers to the Honorary Secretary as an acknowledgement of services rendered to the Association. Mr. Pound warmly thanked the members for the kindness they had shown him, and for such a handsome gift, and also the President for the kind words he had spoken. Mr. Townsend, The Gardens, Sandhurst Lodge, then read his paper on Summer Bedding and Summer Flower Gardens, also the Water Garden. A beautiful collection of *Cinerarias* was sent by Messrs. Sutton & Sons, consisting of their well-known florist varieties and *Cineraria cruenta* hybrids, also specimens of *Cineraria cruenta*, the original type introduced from the Canary Islands in 1777, the object of the exhibit being to demonstrate the result of a cross made between *C. cruenta* and the flowers of the present day, thus showing one generation removed from the original. The hybrids are sweetly scented with a hawthorn perfume, and are exceedingly useful for cutting.

TREE IVIES.

THE value of the Ivy as a climbing plant is well known and undisputed. The value of tree Ivy, however, as an addition to the not over lengthy list of good constituted hardy evergreen shrubs is not so fully recognised. Everyone knows how well the strong growing varieties of climbing Ivy do under most adverse circumstances. When growing in the middle of large towns the leaves keep fresh and green where little else would exist. Very wet or very dry weather does not appear to affect them; whilst for coming unscathed through London fogs the Ivy has few equals. As the climbing Ivy shows to such advantage it is a wonder we do not see the tree forms made greater use of, as they grow freely, made good plants in a short time, and are equally effective whether grown in beds, as groups in the shrubbery, or as specimen plants.

The arborescent form of the typical *Hedera Helix* is often seen to great advantage covering the tops of old trees; other varieties, however, which have much more beautifully marked leaves, are rarely met with. Some of the best varieties for the purpose alluded to are *Hedera Helix arborescens*, *H. H. Ragneriana*, *H. H. azorica*, *H. H. amurensis*, large green-leaved, strong growing varieties; *H. H. foliis aureis*, *H. H. foliis argenteis*, golden variegated; and *H. H. Silver Queen*, silver variegated. *H. H. conglomerata* and *H. H. minima* are dwarf growing distinct varieties. The stems are very short jointed, bearing numerous small green leaves closely packed together. They quickly form nice plants, and are very suitable for planting on rockwork.

Although most of the varieties of the climbing Ivy assume the arborescent form when they get above their supports, the strongest only should be grown as shrubs. They may be kept in the tree form either by grafting on stocks of the common Irish Ivy or by rooting from cuttings. The former is the most expeditious way, the latter the better. When grafting is resorted to the stocks should have all the buds removed from the base to prevent suckering. The stocks should be established in small pots, grafted in February, and stood in a cool case, when a union will be effected in about three weeks. Cuttings should be put in in August in sandy soil in a cool frame, where they will root during winter. If cuttings or grafts are put into too much heat the growths sometimes revert to the climbing form. Whether grown from grafts or cuttings it is advisable to keep the plants in pots until they are planted out permanently. Pots 5 inches in diameter will be found a good size for the purpose. The plants should be potted firm, and loam with a little decayed manure used.—W. D.

THE QUALITY OF POTATOES.

I CONFESS I am somewhat disappointed in failing to observe any further information towards an elucidation of the phenomenon in question—if, indeed, it be in the power of anyone to give it. I have been at some trouble latterly in ascertaining from market gardeners and other growers their views and experience pertaining to the subject, but I fear with, apparently, not a conclusive result, requiring also, as it evidently does, a scientific research as well as an ordinary cultural observation, so cogently advocated by "A. D."

The result of my inquiries, in the abstract, is to the effect that the condition of the weather during the growing period of the Potato was mainly responsible for promoting the ailment in question, as evidenced by the dual extremes of the weather last season—viz., a long period of dryness, succeeded by several weeks of more or less rain during the maturing of the crops, causing "swartuberation," so that the chemical constituents of the tubers were not fully elaborated at the harvesting of the crop. In contravention of this theory, several growers are of opinion that the use of artificial manures, particularly nitrate of soda, instead of good farmyard or stable manure, is a contributory cause towards the evil in question. In illustration of this a grower at Bromsgrove, from where a large proportion of the Birmingham market supplies come, informed me that a few years ago he planted a large breadth of Potatoes on a piece of old virgin turf, but without manure of any kind, and at the earthing-up period he sowed a good sprinkling of nitrate of soda along the rows. But, unfortunately, the protracted dry weather precluded the plants from assimilating the virtues of the condiment until the presence of the autumn rains, when a vigorous growth ensued, resulting in the discolouration of the tubers when cooked in a more than ordinary degree, inasmuch that the grower has ever since eschewed the use of the nitrate, excepting for other vegetables and cereals. As regards the Potato, he now pins his faith to farmyard or stable manure only.

When questioned as to the reason why so large a percentage of cultivators patronise nitrate of soda and other artificial manures, his answer was to the effect that artificial manures are more readily obtained than stable manure; also that many growers do not care for the trouble of "loading back" from market town-made manure. Probably there is a considerable amount of truth in my deponent's asseverations, and which are so far qualified by the fact that, without exception, the best consignment of Potatoes, in regard to quality, I have purchased during the past winter from various sources is one recently procured from him, the variety being either "Bruce" or "Magnum Bonum," and it is noteworthy that the sample is of medium size, thus evidencing the absence of strong or excessive manurial stimulants in their production.

A remarkable feature presenting itself in connection with the quality of the numerous samples of Potatoes procured from several growers

during the past season, and which in regard to size and appearance were all that could be desired, was the apparent absence of any internal symptom of discolouration prior to the cooking for table use, consequently necessitating a trial of the sample before purchasing the stock. The importance of the ailment in question admits of no further demonstration here, and it certainly demands all analytical research, ranging as it also does next of importance to the Potato "murrain" itself, and probably as difficult to combat, if not more so.—W. G.

BUTCHER'S BROOM.

It would be interesting to learn if this somewhat rare and interesting indigenous evergreen sub-shrub has been known to fruit as freely in the British Isles, as it is said to do in the South of Europe. I am partly induced to ask this question at the present time from the fact of having recently seen a small quantity of its branches profusely furnished with bright red berries for sale in Birmingham market halls, and where it attracted much attention and admiration in the way of a newly introduced decorative subject there. The consignment came from the Riviera amongst some cut flowers.

The plant is a familiar acquaintance of mine, as for some years when resident near Stratford-on-Avon I had under my charge hundreds of the plants growing in the shrubberies. Excepting in one or two isolated instances berries were not produced, though flowers were freely expanded in April and May. Perhaps this generally non-fruited proclivity arose from some fertilising disability, owing either to the dioecious character of the species or to adverse climatal influences. Possibly the latter, inasmuch as I believe that in the South of England, and especially in Arundel Castle Park, where it abounds, the plants fruit pretty freely.

Altogether the various characteristics of the plant constitute it one of the most interesting and unique members of our indigenous vegetable kingdom. Its persistent foliage, or, strictly speaking, cladodes, twisted at the base, render it a conspicuous plant in any garden. Botanists assign the genus to a position among the earliest of our plants, and degenerated in character.

Reverting to the habit of the plant, I may remark that if grown for several years in one position it assumes a stunted growth from lack of nourishment required by the numerous fleshy Asparagus-like roots and shoots, indicating the necessity of occasional division and transplanting into rich soil. These conditions also apply to its congener, *Ruscus racemosus*, commonly called the Alexandrian Laurel, and which deserves extended cultivation if only for the sake of its long and graceful shoots, so admirably adapted for decorative purposes. Another species, *Ruscus androgynus*, a native of the Canary Isles, and occasionally to be found in our own country as a greenhouse plant, also lends itself to purposes similar to the last named.—G.

SPRING SHOWS.

TORQUAY.—MARCH 24TH.

THE members of the Torquay District Gardeners' Association held a most attractive exhibition on Wednesday, March 24th, in the Bath Saloons, Torquay. Both financially and artistically this was the most successful show ever held in Torquay. By arrangement with a local firm the large hall, 100 feet by 50 feet, was illuminated with the electric light, and the effect in the evening, when over 200 ornamental electroliers, standards, and brackets were lighted, was extremely beautiful. Many of the lights were placed amongst the flowers and foliage with fairy-like effect.

A select string band, organised specially for the occasion, and including the best local instrumentalists, drew large crowds in the afternoon and evening. There was a record attendance, which included Prince Albert of Belgium, who is now staying at Torquay. The show was formally opened by the Mayor, J. H. Rockhey, Esq., J.P., who was accompanied by the Mayoress, Miss Rockhey, Dr. R. Hamilton Ramsey (President of the Society), and a number of other leading residents. The Committee, Judges, and honorary exhibitors had previously lunched together.

With regard to the show itself, many present observed that they had never seen a finer spring exhibition. In the centre of the hall was arranged a large group, consisting of high Palms, surrounded by a brilliant bank of flowering plants. This was contributed by Messrs. W. Burridge & Sons and Messrs. Horn & Sons, both nurserymen, and formed an effective centrepiece. Messrs. Curtis, Sanford & Co., Limited, showed a most attractive stand. The South Devon Fruit Farm contributed a good show of fruit and vegetables. Mr. J. Snelgrove of St. Elmo, Torquay (gardener, Mr. W. Bale), exhibited a grand group of flowering and foliage plants, including many Orchids. Mr. W. B. Smale, J.P., F.R.H.S., was well represented by a showy stand of Palms, Lilliums, and Azaleas, together with a table of cut Narcissi. Messrs. R. Veitch and Son of Exeter attracted much attention with their novelties in the shape of rock plants and Cacti, which, together with their large variety of Narcissi, made up a very lovely exhibit. Messrs. Allward, Beachey, and Co, the Jadoo Fibre Company, and Mr. W. J. Godfrey of Exmouth, also had stands, the latter showing some fine new Zonal Pelargoniums.

One of the most novel features was an exhibit by the Torquay Town Council. This consisted of an imitation garden, with miniature beds laid out in turf and backed with virgin cork and subtropical plants.

The beds were filled with Hyacinths and Tulips, and the display reflected great credit upon the designer, Mr. J. B. Dyer, Corporation head gardener.

The chief prizewinners were Miss Lavers (gardener, Mr. G. Lee), who showed some grand Orchids, including *Lycaste Skinneri alba* and some magnificent specimen *Cœlogynes* and *Dendrobiums*; Dr. W. Ford Edgelow (gardener, Mr. C. R. Prowse), who was first in the miscellaneous group in form of circle: Captain W. Fane Tucker (gardener, Mr. J. Sloman), with some well grown *Narcissi* and *Hyacinths*; and Mr. P. W. Bushby (gardener, Mr. F. Peacock), who won the first prize in the table decorations with an extremely light and effective exhibit; and Mr. J. W. Kimber (gardener, Mr. F. C. Ferris). The Judges were Mr. W. Swan of Bystock, Exmouth; Mr. W. Rowland of Parker's Well House, Exeter; and Mr. T. Pender of the South Devon Fruit Farm, Mr. F. C. Smale being the Hon. Secretary.

ROYAL BOTANIC.—MARCH 31ST.

THE spring show of the Royal Botanic Society was held in Regent's Park on the above date. As a competitive exhibition it was very poor, for so far as we could see there was no competition in any class, save the one for twelve pots of *Cyclamens*. Miscellaneous exhibits from nurserymen, however, made a bright display, and were as a rule of high quality.

Mr. J. G. Mowbray, gardener to Major the Hon. H. C. Legge, Fulmer, Slough, was apparently the only exhibitor in the class for six Chinese *Primulas*, receiving the premier prize for splendidly grown specimens. Mr. W. Rumsey, Waltham Cross, was placed first for six *Roses* in pots with fairly well-flowered plants. For twelve *Cyclamens* the St. George's Nursery Co., Hanwell, secured the chief award. The plants were admirably grown, and carrying fine flowers and good foliage. Messrs. Petridge, Brentford, were a fair second.

The *Hyacinths* staged by Messrs. Morle & Co., Finchley Road, in the class for twelve, distinct, and for which the first prize was awarded, were barely of average merit. For twelve *Amaryllis* Mr. H. Perkins, gardener to the Hon. W. F. D. Smith, Henley, was first.

Though competitive exhibits were very meagre, collections staged by the various nurserymen were numerous and of high quality. Messrs. Barr & Son, Covent Garden, staged *Narcissi* from their Ditton Nurseries. Amongst others were noted *Duchess of Westminster*, *bicolor Victoria*, *Barri conspicuus*, *Emperor*, and others. The same firm sent *Tulips*, *Fritillarias*, *Primulas*, and *Muscari*. Mr. R. Scott, gardener to C. Newington, Esq., The Holme, Regent's Park, arranged handsome flowering and foliage plants that made a bright display.

The St. George's Nursery Co., Hanwell, exhibited a large number of *Cyclamens*, as did Mr. Petridge, Brentford. Splendid *Camellias* in pots came from Messrs. Wm. Paul & Son, Waltham Cross. Such varieties as *The Duchess*, *alba plena*, *Cup of Beauty*, *Duchess of Teck*, and *Beauty of Waltham* were very conspicuous. *Azaleas* formed the major portion of the exhibit from Messrs. J. Peed & Sons, Norwood, though *Boronias*, *Ferns*, *Prunus*, *Palms*, and others were included.

Messrs. J. Laing & Sons, Forest Hill, exhibited miscellaneous plants of fine quality. There were *Crimson Rambler Roses*, *Clivias*, *Anthuriums*, *Crotons*, *Ferns*, *Caladiums*, and various *Orchids*, with some plants of the yellow *Calla Pentlandi*. *Magnolias*, *Clivias*, *Crimson Rambler Roses*, *Boronias*, *Acacias*, and *Ericas*, with *Ferns*, came from Messrs. W. Cutbush & Son, Highgate. Superb *Amaryllis* were sent by Messrs. J. Veitch & Sons, Ltd., Chelsea, also a few *Orchids* and a collection of *Daffodils* and blue *Primroses*. The *Emperor*, *Empress*, *Glory of Leyden*, and *Barri conspicuus*, *Narcissi* in this group were very rich in colour, as were the several others not noted. Mr. G. Mount of Canterbury staged cut *Roses* in his customary excellent style, while Mr. W. Rumsey, Waltham Cross, sent plants in pots.

PARIS GREEN FOR THE CABBAGE CATERPILLAR. — An agricultural paper of high character states that we may freely use Paris green on the Cabbage in order to destroy the Cabbage caterpillar. It states that the ordinary solutions of Paris green do not contain enough poison to injure anyone; but the danger would be that the solution would sometimes be made much stronger than was desirable, and there can be no doubt there would be many fatal cases if Paris green should become general in this case. The use of Paris green should be strongly objected to in the case of any vegetable, like the Cabbage, which retains within its closed leaves whatever may be cast upon it. In cases where the poison can be easily washed off by the rains, there would not be the same objection. — ("Meehan's Monthly.")

IRIS JAPONICA — This beautiful *Iris*, says a writer in an American contemporary, which has been in cultivation nearly a century, ought to be in every collection of cool greenhouse plants. It belongs to the rhizomatous section of the genus, and is perhaps better known as *I. fimbriata*. The bright green sword-shaped leaves are from 1 foot to 18 inches in length, gradually tapering to a point, and are arranged in fan-like tufts, making an elegant plant even when not in bloom. The pale lilac or bluish flowers are 3 inches in diameter, and beautifully fringed. The reflexed falls are a rich orange-yellow at the throat. The individual flowers are fugitive, but they succeed each other until each spathe has produced three or four. The plant blooms better when allowed to become pot-bound. My experience has been that it is best not to attempt to divide the roots until this is absolutely necessary, as the plant will not blossom till the second season after division.

THE YOUNG GARDENERS' DOMAIN.

FREESIAS.

THESE delightful winter and spring-flowering bulbous plants are not so extensively grown as they deserve to be. They are of easy culture, and the deliciously scented flowers are produced with great freedom under good cultivation. A compost of two parts loam, one of leaf mould, with a small quantity of silver sand, and half a part of decayed manure, will be found suitable for these plants.

We use 4-inch pots, well drained and clean, with a layer of moss placed over the drainage to keep it clear. Six bulbs are usually inserted in each pot about September, and plunged in cold frames up to the rims of the pots. When starting into growth they may be removed and placed in a position near the glass. A few pots at a time placed in a gentle heat of 45° to 50° at short intervals produce a succession of flowers from Christmas until March, or even later.

As soon as the plants are large enough to tie they should have a thin stake put to each growth. Some good artificial or weak liquid manure may be given at intervals of about a week, which will prove beneficial to the flowers, and an occasional watering of clear soot water may also be given to impart colour to the foliage.

Freesias are less subject to insects than most plants, although red spider, thrips, and green fly will sometimes attack them. These troublesome pests may be eradicated by syringing with the XL All liquid insecticide, mixed according to the directions given. These plants are admirably adapted for either house, table, or conservatory decoration, producing a pretty effect by their arching flower spikes, and the individual flowers are also useful for buttonholes, sprays, and bouquets, as they wire well, and are the right colour for that purpose.

After flowering they may be placed closely together in cold frames, and watered regularly until the foliage shows signs of maturation, when water should be gradually withheld until the soil becomes quite dry; they should be fully exposed to the sun, so as to well ripen the bulbs. — J. F. D.

POTTING FREESIAS.

IN your issue of the 25th ult., in "The Young Gardeners' Domain," the writer on *Freesias* says, in potting the bulbs, twenty should be placed in a 32-pot to get a mass of foliage and flowers. I should think he would get too much of a mass. We find that ten to twelve are sufficient for that size of pot. — WORPLESDON.

FUCHSIAS.

EXCEPT for the production of cuttings I do not advise keeping old plants of *Fuchsias*. Specimens 4 feet in height and 2 feet in diameter can be obtained in one season if the proper treatment be afforded them. The cuttings should be taken when about 2½ inches long in the month of February from old plants previously started in heat. Placed in small pots and plunged in a brisk bottom heat with an atmosphere freely charged with moisture the cuttings will root in about a fortnight. When rooted, and before the roots become matted together, pot singly in 3-inch pots, using a mixture of three parts loam, two parts leaf soil, and one part sand, thoroughly well mixed, returning them to the plunging material for a few days. When the roots have taken hold of the fresh soil remove the plants to a position on a shelf near the glass in the same structure, where they will have plenty of light and are within easy reach of the syringe. Do not top the leader, for if given room enough plenty of shoots will be produced from the axils of the leaves to furnish the plant. The great secret is to keep the plants moving until the required dimensions are obtained. Heat and moisture with ample space are essential to the well-doing of the *Fuchsia* during the growing season.

About the end of July the plants should have grown to their fullest extent (being probably in 12-inch pots), when they should have more air. About the end of August they can be safely removed to a position out of doors on a bed of coal ashes, where they will receive the full benefit of the sun in order to ripen the wood. During their brief stay out of doors no pains must be spared in keeping the plants well supplied with water both at the root and also overhead with the syringe, giving the plants an occasional twist round to insure the thorough ripening of the wood on all sides, and to prevent their rooting into the ashes on which they are placed. When the wood is of a light brown tint transfer the plants to an airy structure, and continue syringing until the flower buds appear, when it should be discontinued. The application of weak liquid manure will assist the plants after they have become root-bound. *Fuchsias* should not be tied more than is absolutely necessary, otherwise their pendent and graceful habit cannot be appreciated. — YOUNGSTER.

SALVIAS.

FOR conservatories and greenhouses *Salvias* form an excellent succession to *Chrysanthemums*, and by growing three or four varieties *Salvias* can be had in flower from early in December till the middle of April. Give the plants the same care as we give to *Chrysanthemums*, and it will be a cause of astonishment to all who see them why such plants are not more grown, and why we do not treat them better during the summer than planting them out in some remote corner and letting them grow as best they can; many following this practice, and like most neglected plants, the return is small. Could we always bear in mind that what is worth doing is worth doing well, many partial failures would be unknown.

The four most useful *Salvias* are *S. gesneræflora*, *S. Heeri*, *S. splendens*, and its dwarfier variety *S. Bruanti*, which is a lovely variety, brilliant in

colour and dwarf in habit, requiring the same treatment, and flowering the same time as *splendens*. Their culture is easy. Take cuttings in March, and insert several in a pot, according to the size used, place in a close case, and if there is a slight bottom heat they will root the more quickly. When rooted potted singly, and inure the plants so that they experience no check when placed on a greenhouse shelf near the glass, or better, in a heated pit till the end of April. They must have plenty of air and light, or they become drawn and weak. Repot and arrange them in a cold frame during May; after the first week of June they may be placed outside, shifting as they require till established in their flowering pots, which may be 12 inches in diameter, during July. Compost—loam seven parts; horse droppings, prepared as for a Mushroom bed, one part; half a part of wood ashes, and a dusting of bone-meal. Pot firmly, and assign the plants an open position, to induce short and stocky growth.

They will require frequent topping till the end of August to form compact and bushy plants. *Salvia splendens* is the first to flower, opening during December, when its brilliancy will make the houses gay during the dark days about Christmas. It requires careful staking and a sheltered spot, as when grown strongly it is very brittle. On this account some persons grow the plants in cool houses all the year, which I consider unnecessary. *Salvia Heeri* is the next to bloom, opening in January and early February. It is not so nice a grower as either *S. gesneriflora* or *S. splendens*, being taller and longer jointed. *Salvia gesneriflora* flowers during March and on into April.

The varieties mentioned flower over a period of four months, and are the best I know for winter flowering. *S. splendens* can almost be had in bloom at any time through early or late propagation. As to watering, do not give them too much—they may be kept drier than *Chrysanthemums*—and do not overfeed them with manures, as rank growth is not desired.—W. T., Ireland.

CONSERVATORY MANAGEMENT.

THE conservatory will next (October) be ready for the reception of the *Chrysanthemums*. About the culture of these plants I shall have little to say at present. In the arrangement of them it is better not to mix the varieties of incurved and Japanese together. A better effect is produced if they are grouped separately. *Chrysanthemums* grown in small pots are very useful for edging. For this purpose cuttings may be taken in June or July from plants which have been planted in a border for lifting in the autumn; 5-inch pots are very suitable. Insert seven or eight cuttings in each pot, using a light compost. Place them in a frame, which should be kept close, and shaded in sunny weather. Slightly damp them morning and afternoon. When the cuttings are rooted they may be taken out, and the pots stood thinly on ashes. Do not allow the plants to become dry, or the leaves will turn yellow. Afford liberal supplies of liquid manure when the pots are well filled with roots. By the end of October they will be nice serviceable bushes about 1 foot in height. *Sœur Melaine*, *Rosinante*, *Nellie Rainford*, *Précocité*, *St. Michael*, and *Elise Dordan* all flower well under this treatment.

During the time the *Chrysanthemums* are in flower as little heat as possible, consistent with safety from frost or damping, will be needed. With good management the blooms will be attractive all through November, and a few late sorts will prolong the display well into December. By this time, cuttings having been already taken, the plants may be removed. With the departure of the *Chrysanthemums*, we come again to the *Camellias*, *Cytisus*, and *Heaths*. These will not yet be in full bloom, but the house may be enriched by the addition of *Poinsettias*, which stand remarkably well. Their scarlet bracts make quite a brilliant display, intermixed with the *Cytisus*. The advent of the new year completes the twelve months round of conservatory management.

In giving the names of the various plants which I have mentioned, I have not done so with the intention of excluding others, which may be equally as serviceable. My main point has been to name collections which will closely succeed each other in flowering, and form the nucleus of the display in their respective seasons. I should, however, exclude the common *Geraniums* (*Zonal Pelargoniums*), with which many conservatories appear to be furnished almost all the year round. I do not favour the introduction of these plants, handsome though they be, excepting in the late months of the year. The flower garden is a more suitable place for them in the summer, and one great object in conservatory management should be to provide a display in the summer entirely distinct from the flower garden, or the house will lose half its significance.

Of the general work in connection with the conservatory a little remains to be said. All plants ought to be thoroughly cleaned before being removed to it. Any that need should be neatly staked and tied, also the pots washed. Each morning all dead leaves and flowers should be picked off, the floor brushed over, afterwards watering the plants. Do not allow pools of water to remain on the floor, but have a pail and cloth handy with which to dry it. Whoever is in charge should complete this work as the first of each day.

In the foregoing I do not claim to have presented to the reader an ideal conservatory. At the same time, I confidently believe (judging from the knowledge gained during my own short experience) that if a house is managed in a somewhat similar manner to what I have attempted to describe the result will be a gay conservatory all the year round, and a source of pleasure to all concerned.—P. W.

[A very well written and creditable series of articles.]

FRUIT FORCING.

Cucumbers.—As the sun heightens, and the light and heat correspondingly increase, attention must be given to needful shading and due supplies of moisture in the atmosphere and at the roots. Flagging must not be allowed whether it arise from exposure to too powerful sun or a deficiency of moisture, as it gives a check highly prejudicial to the plants at the time and cripples them in their after growth, therefore light shading at this time of year is often desirable for a couple of hours at midday when the sun is powerful. Damp the floors and other surfaces in the morning and evening, and syringe the plants lightly and both ways on fine afternoons.

Plants in bearing will need liquid manure once or twice a week, and the roots earthing occasionally. There is nothing like fresh sweet material, such as turfy loam laid up till the grass is killed, with one-third of horse droppings prepared as for Mushroom beds, for encouraging the growth of roots, and with plenty of these the plants can be fed to any extent, there being few stimulants that act more in favour of Cucumbers for quickness, clearness, and greenness than nitrate of soda, half an ounce being used per gallon of water, and all the waterings supplied in a tepid state, always as warm as the bed. Other food of a sustaining nature must also be afforded. Where stable drainings are obtainable they may be used with advantage, neat being diluted with five or six times the bulk of water, care being taken not to apply it too strong. If horse droppings are used as a mulch they must be well sweetened before being introduced to the house, or the ammonia will injure the foliage. Worms sometimes become troublesome, and are best expelled by placing a peck of freshly burned lime in 30 gallons of water, allowing it to stand two or three days after stirring well, then using the clear lime water, or a peck of soot to 70 gallons of water. The lime acts well on organic matter and all *vermes*, including eelworms, as well as on organic matter, and the soot is a good fertiliser, putting plenty of colour into the fruit; but the clear only should be used, letting stand forty-eight hours after stirring and drowning the soot. Canker in the stems may be subdued by rubbing quicklime into the affected parts, repeating as necessary, and avoid wetting the stems.

Attend to stopping and tying the growths not less frequently than once a week, cutting out exhausted growths and encouraging young bearing shoots. To keep the plants in steady progress and secure straight, clean, tender, crisp, well-flavoured fruit a temperature of 65° to 70° at night, 70° to 75° by day artificially, 80° to 85° with sun, closing sufficiently early to run up to 90° to 100°, with abundance of atmospheric moisture will be suitable. Ventilate early but moderately, avoiding sudden changes of temperature, pernicious cutting winds, and currents of cold air, which cripple the foliage and deform the fruit.

In pits and frames the necessary heat should be maintained by lining the beds, renewing as required, taking care to avoid rank steam inside the frames. Train the growths rather thinly, and stop them one or two joints beyond the show for fruit. Supply fresh warmed soil to the hillocks or ridges as the roots extend, and be careful that the application of water is not excessive. Admit a little air early so as to dry the foliage before the sun acts powerfully upon it. Keep the temperature through the day at 80° to 90° from sun, and close early in the afternoon, no harm accruing if the temperature rise to 90° to 95° provided there is no rank steam.

Figs.—*Earliest Forced Trees in Pots.*—Early Violet and St. John's, very early small fruited varieties, are advanced towards ripening, and the foliage must be kept dry as soon as the fruits show signs of changing. Less water must also be given at the roots, and liquid manure need not be applied, as too liberal feeding in the ripening stages prejudices the quality of the Figs. Water, however, should be furnished to the roots so as to maintain the foliage in health. Trees swelling their fruits need full supplies of water and liquid manure until ripening commences, when a circulation of warm air will be necessary to secure well-ripened high quality fruit. The temperature will need to be maintained at 60° to 65° at night, 70° to 75° by day from fire heat, 80° to 85° with sun, admitting air or increasing it from 75°, closing the house early so as to advance to 90° or more.

Planted-out Trees.—Such Fig trees are often unsatisfactory, growing very often too luxuriantly, and are frequently trained to walls at a considerable distance from the glass, so that they produce wood instead of fruit. This can only be overcome by lifting and restricting the roots, and training the growths thinly. They cannot be too near the glass, provided they do not touch. When the foliage has abundance of light, and the roots are plentiful and active in borders of limited area the trees require liberal feeding. This is easily effected through the surface roots, which are encouraged by a mulching of partially decayed manure, preferably lumpy, and if kept moist will be permeated with roots by the time the most support is needed to perfect the crop. Fig trees will take almost any amount of liquid manure without prejudice to the crop, and it is astonishing what heavy crops the trees will carry with the roots confined to narrow borders.

Melons.—Stout leathery leaves, short-jointed growths, usually produce heavy high-flavoured fruit; thin foliage and long-jointed wood produce the exact opposite, solidification being essential to fertility. No effort should be spared to get fruit set on the first laterals. When in flower and during the setting period water should only be given to prevent flagging, and the atmosphere must be kept dryer, with an increase of temperature of about 5°, a circulation of warm air conducting to a good set, and if necessary a little air should be admitted at night to prevent the deposition of moisture on the flowers. Fertilise the blossoms every day, pinching each growth at the same time one joint beyond the fruit. When the fruits are set and about the size of a hen's egg give a thorough watering with tepid liquid manure, having the soil for earthing the roots warmed, for if the roots are chilled by cold water or soil the fruits turn yellow instead of swelling. In a day or two after watering top-dress with rich, turfy, rather strong loam, pressing it down somewhat firmly, and again supply water. Stop the subsequent growths to one or two leaves, and avoid overcrowding the foliage by removing superfluous growths. The bottom heat should be kept steady at 80° to 85°, this assists the swelling of the fruits, and speedy growth with early ripening is a great point in growing the first crop of Melons. The night temperature may stand at 65° to 70°, 70° to 75° by day from artificial means, ventilating from that point, but allowing an advance to 85° or 90°, closing at 85° sufficiently early to rise to 90° or 100°.

Syringe moderately about 3 P.M. on bright and warm afternoons, or soon after midday when the air is sharp. Damp the floor in the morning, and keep the evaporation troughs charged with liquid manure, or failing these sprinkle the floor with stable drainings diluted with five times the bulk of water, unless sufficiently diluted by washings running into the tank. Liquid manure will be needed by plants in restricted borders; and a mulching of rather lumpy and sweet manure encourages roots, and affords support. Water, liquid manure, and mulching must always be applied equal to or in advance of the temperature of the house.

Later plants will need the growths trained regularly, removing the laterals on the stem to the trellis, then rubbing off every alternate one directly they are perceived, leaving the rest on the right and left of the main stem, pinching the point out of the primary stem after it has extended two-thirds of the required distance. Increase the supply of water as the days lengthen, but avoid making the soil too wet, as that hinders root action, and secure a genial condition of the atmosphere by damping in the morning and lightly syringing on fine afternoons.

Sow seeds to raise plants for occupying small houses or pits as they become cleared of bedding plants, keeping the plants sturdy by growing near the glass, and not allowing them to become very much root-bound. In pits and frames a bottom heat of 80° should be maintained that are growing freely; newly made beds will have a bottom heat of 90°, which is safe for planting out, and as the heat declines it can be increased by renewing the linings, employing thick night coverings over the lights.

PLANT HOUSES.

Azaleas.—As these go out of flower pick off the seed pods, and place the plants where they can be assisted by gentle heat and moisture to make their growth. Those which flowered early and have started into growth may be repotted if they need it. We have found loam and leaf mould in equal proportions with the addition of coarse sand as good as peat for growing Azaleas. The soil should be pressed firmly, so that water will not pass through, the new and leave the old balls of soil dry. Plants required for late flowering should, if practicable, be placed in a house with a north aspect. Careful watering is essential, and the syringe may also be used freely to keep thrips in check; if any are seen the best method of destroying them is a thorough application of weak tobacco water.

Erica hyemalis.—If the plants are not repotted the work should be done at once. Do not give them a large shift, and use peat and sand as a compost. In potting do not disturb the roots further than is necessary in the removal of the drainage. If the new soil is pressed firmly the roots will soon take possession of it. Where convenient place the plants in a frame, where they can stand on a base of ashes and be safe from frost. The plants may be syringed early on fine afternoons and the frame closed.

Camellias.—Those which have flowered may be kept close and warm to promote free growth. They enjoy much water at the roots, and the syringe should be used freely. While growing these plants are benefited by shade, which should be gradually removed, so that they can be fully exposed by the time the foliage is developed. This is necessary to ripen the wood and the production of buds. Plants that need repotting will grow freely in good fibry loam, with one-seventh of cow manure and sand. Those in large pots and tubs may be top-dressed with rich material, while those planted out if they are weakly may be supplied with stimulants.

Greenhouse Rhododendrons.—These may be kept with Camellias during the period of growth, and then fully exposed to the sun. The way in which they flower another year entirely depends upon the amount of light and sunshine they receive during the growing season. Any plants that need larger pots should be afforded them when flowering ceases. R. Gibsoni and Princess Royal are excellent for planting out to cover a wall, and when established they flower profusely. The latter has been furnishing flowers since last October. For shallow glasses and table decoration the flowers are invaluable. The plants grow well in peat and sand.

Daphne indica.—These plants are frequently destroyed by trying to push them forward in a close atmosphere. After they have flowered place them in frames where they will enjoy a cool base and plenty of air. Apply water carefully, but do not allow them to become dry.

Epacris.—Cut back all that have done flowering, and keep them slightly closer until they break into growth, when they may be repotted if they need it. Careful watering for some time is necessary after repotting until the plants are rooting freely in the new soil. Those that were potted some time ago and now growing freely should have plenty of air, so that a firm but sturdy growth will be made.

THE BEE-KEEPER.

LARGE HIVES.

I AGREE with "G. H." (page 240) when he states "that large hives need less attention as to feeding," but he does not say why this is so. It is, however, a fact well known to the majority of bee-keepers who have studied the question that bees will not store a surplus in supers until the brood nest or body of the hive is filled with bees, brood, and honey. If the hive is larger than is necessary by the time this takes place the honey flow will be nearly if not quite over, and little surplus will be stored in supers. This may be quite satisfactory from the bees' point of view, but is not to be recommended to bee-keepers who are anxious to make a profit and obtain a superior sample of honey from their bees.

It must have been a hive similar to the above that "G. H." had in mind when he stated in a previous issue that "if we want to take as much surplus as 250 lbs. and leave 100 lbs. for stores we must go in for larger hives." I fail to see where the advantage to the bee-keeper comes in, except it is in the saving of a little labour in feeding the bees for winter after the honey flow is over. This is really such a simple operation with a rapid feeder that it is not worth taking into consideration.

Our seasons are too short and the weather too precarious for bee-keepers to depend on extra-sized hives if their only recommendation is that of holding a large amount of stores in the brood nest. I am not prejudiced in favour or against any frame or hive, knowing full well that it is quite immaterial to one who understands their management, for in the latter word lies the whole secret of successful bee-keeping. Practical experience has taught me that a medium sized hive in this uncertain climate (taking one season with the other) is better than large unwieldy hives.

At the present moment I have some large hives stocked with bees that would probably gladden the heart of "G. H." They were not fed last autumn, or if they were only a small quantity of syrup was given to each, as they had plenty of natural stores, and are now in good condition, being as good as any in my apiary.

These stocks are always worked for sections, and so are some of my hives holding ten frames, standing side by side. The latter for this purpose have never any extra bees given to them, as they are supered when they require it, and the crates of sections are placed one above the other. Treated in this manner I have invariably found them to give better results than the extra large hives. It is honey in supers, not in the brood chamber, that the majority of bee-keepers require.

Whether the hives be large, small, or medium-sized, a bee-keeper is wise to keep to the size that answers best in his district. Frames, too, should always be of the same dimensions, whether large or small, throughout the apiary, as this adds very considerably to the pleasures of bee-keeping.

EXAMINATION OF STOCKS.

During a spell of fine weather lately all stocks in my apiary were examined. This was the first thorough overhauling they have had since last autumn. With the exception of some colonies of bees that were driven from straw skeps late last autumn they are in good condition. The latter were found to be short of stores. But on the whole they are not as strong as they have been during the past two years at this season.

Breeding was going on apace, and in some of the strongest stocks bees were found distributed over all the frames (it being the middle of a fine day) cleaning them and getting them in readiness for their future requirements. An ordinary observer looking in when the quilt was first lifted would think the hive was full of bees, but such was not the case, as during the cold nights which followed they would cluster over the brood on four or five frames only. The night temperature was much too low in my apiary for the bees to be "fanning at the entrance at nine o'clock in the evening," as mentioned by "G. H." on February 20th, as on that

date the maximum temperature was 50° and the minimum temperature 45°, with high wind and rain in the evening.

Judging from the condition of my own bees and others in the neighbourhood the past winter cannot be classed as a good one for bees, owing to the excessive rainfall of the past six months. More favourable weather may now be expected; the brood nest will then expand, and bees will increase at a rapid rate.

DRONES IN HIVE.

Although these cannot be dispensed with later in the season they are not required as early as the first week in March, as mentioned by a correspondent, page 240. When drones are observed in hives, either very early or late in the season, there is usually a cause for it, and in the majority of cases the stock is queenless, or the queen is old, or through various causes her ovipositing powers are on the wane. The workers are the first to detect this; if it happen in the autumn the drones are not killed off, and if the stock is queenless the bees will gradually dwindle away, until the few remaining drones and workers are found dead in their hive the following spring. But when the queen has lived throughout the winter and succumbed after laying a few eggs the following spring, from which a few drones will invariably be raised, the same thing will happen if the queen is old and worn out.

I have had a practical illustration of this within the past few days. On lifting the quilt from one of my hives I saw a solitary drone cell with the grub well advanced. I was at once convinced something was wrong with the queen, and on examining the stock found her dead in the hive, although there were plenty of bees and brood in various stages of development. — AN ENGLISH BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

•• All correspondence relating to editorial matters should be directed to "THE EDITOR." Letters addressed to members of the staff after remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return rejected communications.

Spawning of Toads (*W. P., Wilts.*).—Toads visit the water in March or April, their breeding season, for the purpose of depositing their eggs. Damp places are absolutely necessary for breeding purposes, even in the case of the dry land or common toad (*Bufo vulgaris*).

Tulips "Blind" (*J. A., York*).—The Tulips are quite clear in the bulb, and have abundance of white, remarkably healthy roots, nothing whatever being amiss there, while the leaves are large, deep green, perfect pictures of health; the stem also short and stout, but, as you say, "blind." The flower bud never appears to have been much larger than a pea, hence we consider the failure due to the imperfect formation of the flower bud in embryo, or what is generally termed unripeness of the bulbs. You ask, "Is it through any fault in the cultivation?" Certainly not, as regards the bringing of them into flower, for no one can place flower buds in "blind" bulbs, and that appears to have been the fault. The buds, however, have the mycelium of a fungus (*Botrytis galanthina*, the conidial condition of *Sclerotinia bulbosum*) in them, but we do not consider this to have been the cause, but rather the consequence of the "deaf" flower bud and its decay.

Discoloured Tomato Leaves (*F. L.*).—The specimens shall be microscopically examined as you desire. They did not reach us in time for this to be done and the results published in the current issue.

Swollen Peach Roots (*J. L.*).—Your letter, with Mr. Abbey's reply on the subject, we expect to publish in our next issue. Our diligent searcher and experimenter has not only discovered the cause of the swellings, but another, what we may term "miticide."

Spiræas with Dead Flower Stems (*A. Boyling*).—The stems are browned and dead from the top of the should-have-been panicle to a little below, and have the appearance of having had the part destroyed by some grub burrowing in the stem and eating out the pith, as some are hollow, and where not hollow brown as if permeated and killed by some fungus. We could not, however, detect either, therefore can only account for the flowering stems dying through the plants being brought on too rapidly, the temperature being too high and the plants at too great a distance from the glass. We have had similar, and were unable to account for their condition in any other way. Indeed, plants of the same batches in a vinery were complete failures and others in a Peach house flowered splendidly, the difference in temperature being 10° to 15°, and the amount of light and air about twice as much in the latter as former structure. This—forcing too rapidly—we consider at least one cause of failure, the plants having run to leaves and impoverished the flowering parts.

Yellow Spots and Blotches on Tomato Leaves (*W. J. H.*).—The yellow parts of the leaflets are traversed by the mycelium of some fungus which has abstracted the substance and caused a slight depression, but we cannot detect any outgrowths, or only one, and that appears to be the stalk or conidiophore of the smother fungus (*Botrytis cinerea sclerotiphila*), the conidial condition of *Sclerotinia sclerotiorum*, *Mass.* The fungus ultimately forms a mould on the dead tissue, and amid the small externally black sclerotia, once called *Sclerotium durum*, from which spring the conidial stage again, the *Pezizæ* being produced by the final stage, which forms a smother mould on the roots and stems of Potato, Cabbage, Beet, and Turnips, the conidial condition being suppressed. There is one of the spores (conidia) on a hair and pushing a germ-tube. You have done well to burn the infested plants, for it is the most malignant of the Tomato fungi, and in the conidial stage has swept off whole fields of Turnips in the North of England, where it was very prevalent last year. It cannot live in a dry atmosphere, being essentially a damp-loving fungus, as also is the species *B. cinerea*, sometimes found on Vines in vineries, turning the leaves yellow and then brown in places as if scorched. Afford plenty of air, and do not over-water, then the parasite cannot make much headway, as it must have a close moist atmosphere and a succulent plant to thrive on. By plenty of air we mean that atmospheric condition essential to a sturdy, short-jointed, fruitful growth. To prevent further mischief you might use some fungicide in powder, such as anti-blight, fostite, and other preparations of sulphate of copper, a very light dusting being all that is necessary. But hardness of tissue in the plants is of the first importance, together with removing the spotted leaves promptly.

Insect on Apple Twig (*Kentish Gardener*).—The ring-like band on the Apple tree shoot is that formed by the lackey moth (*Bombyx neustria*) in depositing its eggs, which are laid in the late summer or autumn of the year preceding that in which the attack of the caterpillars takes place. The eggs are arranged around the twig in regular order. When the caterpillars hatch they at once spin a web over the nest or shoot on which the egg-band has been placed, so that they have a snug shelter. There had been nearly 200 in your specimen. The caterpillars are black when hatched, and have an enormous head for their size. They cast their skins several times, and at last come out, so to say, in full dress, and are styled "livery" caterpillars. This is about mid-summer, when they are about 1½ inch long, and have abundance of hairs some a quarter inch in length. The ground colour of the body is a bluish grey, and there are two black eye-like spots on the head, three orange or scarlet stripes along each side of the body, and between the two lowest of these a blue stripe, the whole set off by lines of black or black spotted with blue. They then scatter themselves separately, spin cocoons, become brown pupa, and towards the end of summer the moths emerge, resting by day, and active at night. In the matter of destroying the pest there have been various expedients, such as crushing the eggs with the back of a knife, waiting until the webs are seen, then cutting the twig or shoots through, and destroying the web-nests—a bad French plan. As the caterpillars hatch out about the vernal equinox they may be destroyed easily when tender with any approved insecticide; even the eggs can be "cooked" by spraying with the Coates' solution of caustic soda, 98 per cent., and commercial potash or pearlash, half a pound each to 6 gallons of water, using hot (120° to 130°), in March, or before the buds start growing. That is the best plan. If the buds are swelling before the caterpillars are noticed hatching spray or syringe the trees with a solution of softsoap and petroleum made as follows:—Softsoap, 1½ lb.; petroleum, 1 pint; water, 10 gallons. Dissolve the softsoap in a gallon of the water by boiling, and when dissolved remove from the fire for safety, then add the petroleum, stir briskly till thoroughly amalgamated, add the remainder of the hot water, mix well, and use when cooled to 90° or 100°, coating every part of the trees. This will kill all the young caterpillars it reaches, as well as other pests. If any caterpillars escape spray the trees with Paris green, 1 oz. to 20 gallons of water, or add half an ounce (in paste) to the petroleum and softsoap solution, and thus make an end of the chief Apple tree enemies. Spraying is much more economical than syringing, also more effectual.

Anti-blight Powder (Faithful).—The particular kind used by Mr. Fenn for dusting Potatoes and Tomatoes was Tait and Buchanan's, supplied by Messrs. Barr & Sugden, 12, King Street, Covent Garden, who will send you a leaflet showing the bellows on application. Lists of Vermorel's appliances for the same purpose can be obtained from Messrs. Charles Clark & Co., 20, Great St. Helens, London, E.C. They have been advertised in the Journal.

Chemical Manures for Potatoes (H. F.).—You have not done wrong in applying the kainit broadcast. The superphosphate you may spread in the drills with the sets, a large handful over a length of 7 or 8 yards. The nitrate of soda will be more economically used as a top-dressing immediately the plants are ready for the first hoeing, a handful over a length of 14 or 15 yards—not on the plants nor close round the stems, but evenly scattered on the soil between them. The more finely the substance is crushed the better. Replies to correspondents are published as soon as possible, but many do not reach us in time for answering in the current issue, as in this case. To make sure of immediate replies your questions should reach us on Saturdays.

Anemone fulgens Unsatisfactory (P. J. P.).—There is nothing the matter with the roots, and though the leaves are more or less withered there is not any parasite on them. Probably the plants get too much sun, and are too dry in summer on the south border to store sufficient matter for satisfactory flowering. We have found them thrive best in the half shade of trees in front of a shrubbery, the situation not being dry, but moist, and the soil a good loam. We have also had them very fine in borders shaded from midday sun in summer, and gorgeous in the spring on the moist parts of rockwork. The soil should be of a rather sandy nature, enriched with leaf mould or thoroughly decayed manure. The Apple is Shepherd's Fame, an old orchard variety, not generally grown.

Names of Fruits.—Notice.—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (S. S.).—1, Catillac; 2, Easter Beurré; 3, Ashmead's Kernel. (A. U.).—1, Yorkshire Greening; 2, Newton Wonder; 3, Cox's Orange Pippin; 4, Winter Pearmain. (P. T.).—Dumelow's Seedling; the two Pears are unknown to us, and are in all probability local seedlings. (W. S.).—1, Belmont; 2, Belle Angevine.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, at being often difficult to separate them when the paper is damp. (J. W. F.).—Camellias such as yours come within the category of florists' flowers, and can only be named by comparison in such large collections as those of Messrs. W. Paul & Son, Waltham Cross, and Messrs. J. Veitch & Sons, Ltd., Chelsea. (H. T. H.).—Your specimen is of Butchers' Broom, *Ruscus aculeatus*. (O. B.).—1, *Doodia caudata*; 2, *Asplenium palmatum*; 3, *Sedum carneum variegatum*. (J. V.).—*Cotoneaster Simonsii*. (G. J.).—All your specimens were dead through careless packing. (F. F.).—1, *Dendrobium Pierardi*; 2, *Phalænopsis Stuartiana*. (L. W.).—*Cornus mascula*. (J. H.).—1, *Daphne Mezereum*; 2, *Primula rosea*.

POTATOES—WHAT TO PLANT.

POTATO growers have had such a bad time of it for the last two years, and the present outlook in the trade is so gloomy, that many are asking themselves, not "What shall we plant?" but "Shall we plant at all?" No doubt many fields were sown with Wheat last autumn that would have been reserved for Potatoes had not a higher price for Wheat tempted the occupier to put in that crop. Everything that has occurred since has been in discouragement of the Potato planter, so we confidently anticipate a considerably reduced acreage of the tuber. We earnestly hope we may prove correct, for no doubt over-production has been the chief and almost only cause of the depression in price.

The great desideratum in a Potato nowadays is quality. We can remember the time when the British public was much less critical as regards its Potato supply, and for a good reason, the British public had to take what it could get and be satisfied. That was before the enterprise of Mr. Clarke had given us the Magnum Bonum. Farmers were still growing the old standard sorts, and sending their Regents to market when the disease left them any to send.

Now, however, all is changed; many new sorts of great value have been raised, very much larger crops can now be grown than formerly under the same conditions, and the chief difficulty of the would-be planter is to decide between the rival claimants to his choice.

The growers of second earlies—i.e., varieties which are marketed before October and direct from the land without storing—have had so much the best of it of late that it seems likely that we shall have an undue proportion of second early varieties planted. The chief in this class are Snowdrop, Elephant, Hebron, and Reading Giant. Of these the Giant is the heaviest cropper and the least liable to disease, but generally the worst in quality; it is

apt to boil very black if kept until after Christmas, and it has been bad to sell during the present winter, whereas there has always been a demand for sound Elephants or Hebrons.

The Snowdrop is an excellent cropper, but very delicate, and must be got off early before disease makes its appearance. Jeanie Deans, one of Mr. Finlay's introductions, is very early and a good cropper, whilst the quality is similar to the old Regent, but being a round Potato is against it for early marketing. A moderate acreage of it might do well, say as many as could safely be got away during the latter half of August, but we could hardly recommend it for winter consumption.

All the above varieties require a good well-drained soil and high cultivation. In fact we do not believe in anything but high cultivation in the growth of the Potato.

Since Potato growing has become more general, with the increase in the acreage it has become every day more evident that the supply was over-reaching the demand. This being so, and the markets being flooded with Potatoes at all prices and of all qualities, it is obvious that the result of the keen competition must be the survival of the fittest. This has come to pass. The consumer, finding himself able to obtain the best quality at a low price, has acquired a taste for the best, and will have nothing else. As only good soils can be depended on to produce first-class keeping quality, it follows that the poorer and lighter soils are no longer suitable for growing anything but the early kinds. If maincrop varieties were never planted on any soils but those of good body and colour there would be fewer Potatoes in the markets, and prices might be higher; but there would be little waste in them, and the consumer would not be altogether a loser.

But having got some good land to plant, what kinds are we to put in it? The old "Magnum Bonum," as a kidney-shaped main-cropper, is still worth growing; but the "Bruce" is whiter in the flesh, and to be preferred on account of its more robust habit.

"Maincrop" is probably the best quality of all, at any rate it commands the highest price; but it is a shy cropper, except on land a very long way above the average in condition. No Potato pays better for high cultivation (75s.). There has so far been no kidney-shaped maincropper introduced which is likely to supersede the three above mentioned.

Of oval and round varieties there are several which have been loudly extolled as being absolute perfection. The Garton we tried for three years on different soils. It is a great cropper, but very late, and is much given to cracking. It has also the disadvantage of being round, which at present is not the fashionable shape. We did not find it satisfactory, and gave up growing it.

Her Majesty, a round of Findlay's, is a good cropper, heavier than the Bruce, and very fine in quality. We have grown it with great success in 1894 and 1895, but last year it did not do so well. We shall grow it again, as it is quite the best of the rounds. A great advantage is its early ripening, it being ready to raise and store by September, and it may be marketed in October.

The "Saxons" we have not grown, but have had good accounts of them from those who have. They are great croppers, and hardy; but this season they have shown a tendency to super-tuberation or second growth. Here again the round shape is a disadvantage. We now come to the Potato which we think the most valuable of all. It is a flattish oval in shape, and is named "Up to Date." It has, as a large dealer observed to us, every qualification which is required in a Potato—cropping power, as demonstrated by the Dalmeny trials, where it produced 19½ tons per acre over 8 acres of ground, handsome shape, robust growth (it is the strongest grower we have seen), hardness and cooking quality. As regards the last we can speak very confidently, for we grew it on weak sandy soil beside other kinds which now use very badly (the Bruce is one), whereas the "Up to Date" still cooks beautifully, the crop was about 40 per cent more than the Bruce. We are confident this is the finest Potato yet introduced. Other kinds are "Fidler's Colossal," which is too large; "Imperator,"

which has seen its best day, and Stourbridge Glory. To sum up, the following will be found most reliable for field culture:—

Second Early.—Snowdrop, Elephant, Reading Giant.

Maincrop for Autumn.—Her Majesty or Saxon.

Maincrop for Storing.—Up to Date; Bruce or Maincrop, according to soil.

WORK ON THE HOME FARM.

Except for one heavy thunderstorm the past week has been fine, with strong drying winds. The land has dried wonderfully, and is again in sowing condition, though rather rough in the strong places. Drilling will now be actively followed until all is in the ground.

There are great complaints of the Wheat plant going away. Wire-worm seems to be the cause. The land will roll well now, and nothing stops wireworm better than constant rolling. We have nothing to complain of, but the Wheat is backward, and not likely to come to harvest so early as last year.

Lambing is over, or nearly so. Results vary very much; lambs on neighbouring farms vary from 100 to 165 per cent. of the ewes. There has been a general loss amongst ewes, varying only in degree.

Sheep are nearly all off the Turnips. The markets are much better, and the spring fairs promise to be decidedly dear. Grass is freshening where the land is dry, and a few beasts are turned out to harden. The trade for store cattle is so far disappointing, but dear sheep should have a good effect on the cattle fairs.

The working of fallows has got somewhat in arrear, for the land has been too wet for the last few weeks, and it was of no use wearing flesh off the horses to no purpose. Fortunately, this year's fallows, being in the same course as those of 1893 (a dry season), never were foul, so that the loss of time is not so serious as it might have been. Every horse that can be spared from the Barley sowing must now be kept at work on the fallows. The portion to be devoted to Mangolds must have the final cleaning at once, and then be ploughed and rolled; it will then be ready for ridging and manuring when drilling time comes. In some parts Mangolds are put in early in April; but the 25th is early enough, and especially in low lying fields subject to sharp May frosts, where it would be safer to delay sowing until the beginning of May.

OUR LETTER BOX.

Calf Dying (W. A.).—Your calf died from a disease known as "black leg," for which there is no cure. It may and can, however, be easily prevented. You say the calf was a splendid one. Only calves that are doing too well are liable. At this time of year, when the weather is mild, great care is needed to prevent calves making too much blood. Knock off all rich food, and carefully avoid hot, close boxes or pens. Remember a calf is not an exotic, and does not need pampering. Try to harden them by turning into yards during the day. A seton is also a preventive. Certain grass fields invariably cause black leg among calves, but a calf that is kept up has no business to suffer, plain diet and cool quarters being the two requisites. A calf will die in a much shorter time than twenty-six hours.

REMARKS.

21st.—Cloudy, close, and hazy till 11.30 A.M.; generally sunny after, but not clear.
22nd.—Rain from 1 A.M. to 4 A.M., and dull and damp till 11 A.M.; gradually improving and a little sun in afternoon; slight shower at 5.30 P.M.
23rd.—Mild and sunny throughout.
24th.—Fine, but frequently cloudy; high wind at times.
25th.—Beautiful throughout, though occasionally cloudy.
26th.—Overcast all morning, gleams of sun at midday; rain at 3.30 P.M., and heavy shower at 4 P.M.; gale and drizzle at night.
27th.—Cloudy, with high wind in morning; generally sunny in afternoon.
An exceptionally warm week for the date; about equal to that usual in the middle of May.—G. J. SIMONS.

Messrs. Street & Co., Advertising Agents, of 30, Cornhill, E.C., and 5, Serle Street, W.C., announce that, in consequence of their increasing business and for the convenience of their West End clients, they will open on Monday, 5th April, 1897, a branch establishment at 164, Piccadilly, London, W.

**FINEST SELECTED STRAINS
OF TESTED GROWTH**

BARR'S "LIGHTNING" RUNNER BEAN
A valuable acquisition, bearing in abundance clusters of pods, remarkably early, and of delicate flavour. Per Half Pint, 2/-.

BARR'S MONSTROUS LONG-PODDED BROAD BEAN.
The earliest, largest, and most productive of long-podded Broad Beans, and of fine delicate flavour. Per Quart, 2/6; per Pint, 1/6.

BARR'S "LEMON GLOBE" ONION.
A grand exhibition Onion, handsome in form, of large size, mild in flavour, and a good keeper. Per Packet, 1/-; per Ounce, 2/6.

FLOWER SEEDS.—Barr's Specialities for 1897.
NEW LARGE-FLOWERED CRESTED BEGONIA.
A splendid novelty, the large handsome flowers having crested combs, colours brilliant and varied. Per Packet, 3/6 and 5/-.

BARR'S SUPERB FRINGED PETUNIAS.
Flowers of immense size and deeply fringed, colours rich and varied. Per Pkt., 2/6 & 3/6.

BARR'S Extra Selected LONG-SPURRED COLUMBINES.
Mixed, flowers of great beauty in form and colour. Per Packet, 2/6.

BARR'S NEW SEED GUIDE FOR 1897
will be sent free on application.

BARR & SONS, 12 & 13, KING STREET, COVENT GARDEN, LONDON.
Nurseries at LONG DITTON, Surrey, near to Surbiton Stn., S.W.R.

BEGONIAS.

Double and Single, Gold Medal Collection, for Conservatory and Exhibition, the largest and best in the trade. See Catalogue.
BEGONIAS FOR BEDDING, superb quality, Double, 6s. and 9s. per dozen; Single, to colour, 5s. per dozen, 35s. per 100; 10 colours mixed, 4s. and 28s.; fine mixed, 3s. and 21s.

B. R. DAVIS, YEovil, NURSERIES, YEovil, SOMERSET.

ASPARAGUS.

Strong, healthy three year ASPARAGUS roots, TRUE GIANT, 5s. per 100, packed and carriage paid. Every garden should contain an Asparagus bed. They are easily made, and now is the season to make them.

BIRD & VALLANCE,
Nurserymen, DOWNHAM, NORFOLK.

**SEARCHERS AFTER
TRUE STOCKS OF
GARDEN PEAS
SHOULD APPLY

LINCOLN FOR
THEIR NEW
BOOK OF SEEDS.**

100,000 BEGONIA TUBERS.—Large, erect flowering; Singles, mixed, per doz., 2s. 6d.; per 100, 18s. Doubles, same price. Send for list, free.—J. WELLS, Begonia Nursery, Ryarsh, Malling, Kent.

CHRYSANTEMUMS.—5,000 Good Strong Healthy Plants. 24 distinct Exhibition Varieties, 4s. Winners of the highest prizes ever offered.
DROVERS, F.R.H.S., N.C.S., Nurseries, FAREHAM.

POTATOES FOR SEED.—Myatt's Ashleaf Kidney, Early Puritan, Snowdrop, Beauty of Hebron, Reading Giant, Imperator, Sutton's Abundance, Up to Date, Saxonia, Magnum Bonum, Colossal, Bruce or Stourbridge Glory. Large or small quantities. Popular Prices. Special terms to Seedsmen. Send for List.—KENNELLY, Smithfield Market, Birmingham.

VIOLAS.—For Exhibition, 2s. 6d. per dozen varieties. For Bedding, including such fine things as White Duchess, Blue Gown, Sylvia, Goldfinch, and Christiana, 10s. per 100, in one or more varieties as desired.—W. BAXTER, The Nurseries, Woking.

IMPORTANT TO MUSHROOM GROWERS.
—CUTHBERT'S SPECIALITE MUSHROOM SPAWN. Always alike; most productive. Hundreds of Testimonials. Per Bushel, 5s.—R. & G. CUTHBERT, Seed, Bulb, and Plant Merchants, Southgate, N. Established 1797.

HEATING APPARATUS.—Medals 1875 and 1881. Catalogue of Boilers, Pipes, and Fittings free. W. Jones' Treatise, "Heating by Hot Water," second edition, 216 pages, 2s. 6d.; post free, 2s. 10d.—JONES & ATTWOOD, Stourbridge.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers.
HIRST, BROOKE, & HIRST, Ltd., Leeds.

ORCHIDS.

CLEAN HEALTHY PLANTS AT LOW PRICES.

Always worth a visit of inspection. Kindly send for Catalogue.

JAMES CYPHER,
Exotic Nurseries, CHELTENHAM.

FERNS A SPECIALITY.

We have an immense stock of all kinds of Ferns, Stove, Greenhouse, Filmy, Hardy Exotic, and British, including many very beautiful varieties, rarely seen but which ought to be more generally grown. Catalogue free on application.

W. & J. BIRKENHEAD, F.R.H.S.,
FERN NURSERIES, SALE, near MANCHESTER.

LILIUM AURATUM.

The beautiful golden-rayed Lily of Japan. Magnificent for pots in the greenhouse, or for growing in the open garden. Deliciously scented, quite hardy. Planted now will bloom splendidly during the summer and autumn. Extra fine roots, 10 to 11 inches circumference, per doz., 7s. 6d.; 6 for 4s.; or 25 for 14s. Grand selected roots, 11 to 13 inches circumference, per doz., 12s.; 6 for 6s. 6d.; or 25 for 21s. All post or carriage free for cash with order.

DANIELS BROS., Town Close Nurseries, NORWICH.

CARNATIONS.—Clearance Sale.

A grand collection of choice named double flowered, in beautiful variety, including all the finest sorts. Strong plants from single pots, correctly named, per doz., 4s. 6d.; six for 2s. 6d.; or 25 for 8s. Double crimson Olove, deliciously scented, per doz., 3s. 6d.; six for 2s.; or 25 for 6s. 6d. Packing and carriage free for cash with order.

DANIELS BROS., Town Close Nurseries, NORWICH.

CHRYSANTEMUMS. CLEARANCE SALE.

A splendid collection, including all the most beautiful and popular of the Japanese and incurved varieties; strong, well-rooted cuttings, correctly named, per doz., 1s. 6d.; per 100, 10s. 6d. Extra choice sorts, per doz., 2s. 6d.; per 100, 15s. Six grand new exhibition varieties splendid, the set 3s. 6d. All post free.

DANIELS BROS., Town Close Nurseries, NORWICH.

FUCHSIAS.—Clearance Sale.

A magnificent collection of superb double and single flowered varieties, including the newest and most beautiful sorts in cultivation. Splendid for pot culture or the garden. Strong young plants, from single pots, correctly named, per doz., 2s. 6d.; six for 1s. 6d.; or 25 for 4s. 6d. Extra choice sorts, per doz., 3s. 6d.; six for 2s.; or 25 for 6s. 6d., post free.

DANIELS BROS., Town Close Nurseries, NORWICH.

Journal of Horticulture.

THURSDAY, APRIL 8, 1897.

DAHLIA ANALYSIS—1883-1896.

THE effect of dry and unfavourable seasons is clearly to be traced in the total number of blooms staged at our National Dahlia Show, as compared with the display to be seen there in anything like an average year. For instance, in recent years the two poorest exhibitions were those of 1893 and 1896. Now, if we take the three most important months as regards the growth of the Dahlia—May, June, and July—we find that in those years they were, at all events when taken together, extremely dry, whereas for a moisture-loving plant like the Dahlia, the weather during that particular period cannot very well be too showery. The influence of unfavourable seasons is more clearly to be traced, as might have been anticipated, in the number of Shows and Fancies tabulated, although all sections will be seen, from the following short table, to have been more or less seriously affected. The summer of 1896, although not quite as disastrous as that of 1893, proved in many ways an extremely trying one, owing to the scanty falls of rain, its dry atmosphere, and great heat; moreover, it was preceded by a remarkably dry spring; then towards the end of August heavy rains set in, which, falling on the heated ground, caused the plants to start vigorously into growth when all their energies were required to perfect their flowers.

The number of blooms set up in competition at the last five exhibitions has been as follows:—

	1892	1893	1894	1895	1896
Shows (No. of blooms)...	879	720	894	827	798
Fancies " " " " " "...	340	270	301	287	276
Pompons (No. of bunches)...	267	168	192	210	192
Cactus and Decorative, ditto...	209	264	246	280	220
Singles (No. of bunches)...	138	128	138	102	126

In the above table the number of flowers shown in the classes set apart for three or more blooms of any one variety is not included.

It will thus be seen that the National Dahlia Society's Show, which was held at the Crystal Palace in September last, was an unusually small one, the total number of blooms in all sections falling short of the average for the previous four exhibitions, except in the case of the Singles, which were fairly well represented.

For the eleventh year in succession that refined variety Mrs. Gladstone holds the proud position of premier flower in the list of Show Dahlias. Its records for none of the last four seasons have been, however, quite as good as they were in any of the preceding seven years. The fact is, since the advent of Mrs. Gladstone two other remarkably fine Shows have appeared upon the scene. I need scarcely say that I refer to John Walker, the only pure white Dahlia in the table; and R. T. Rawlings, the leading yellow variety. At no previous exhibition has R. T. Rawlings been as numerously represented as it was last year. Indeed, it was nearly as often staged as Mrs. Gladstone. The oldest Dahlia which finds a place on the list, James Cocker, sent out in 1871, was also unusually well shown. The same may be also said of J. T. West, Duke of Fife, John Hickling, Alice Emily, Earl of Ravensworth, Mr. Glasscock, Queen of the Belgians, and Perfection, which appeared in an unusual number of stands. On the other hand, either the season or the date of the show in respect to it proved unfavourable to the records of Harry Keith, Colonist, Willie Garratt, Henry

Walton, Shirley Hibberd, T. J. Saltmarsh, and many other well known sorts.

There are no fewer than fourteen varieties in the table which have been sent out since the beginning of the present decade. Of these, four were distributed in 1890—viz., Duke of Fife, John Hickling, Majestic, and Alice Emily. Both Duke of Fife and John Hickling have done good service, having been consistently well shown at the past four exhibitions. They now stand together at No. 17. The records of Majestic have also been very regular, and since last year it has risen from No. 28 to No. 26. The fortunes of Alice Emily have been a little more varied, but last year and the year before it was better shown than in previous years, and consequently rises from No. 40 to No. 36. Coming to the 1892 varieties, mention must first be made of John Walker, which stands at the head of all the newer sorts, and, as before stated, only second to Mrs. Gladstone. Its records for the last three shows have been as follows—29, 30, and 29, which taken together are exactly the same as those for the premier flower, owing to Mrs. Gladstone

SHOW DAHLIAS.

Position in Present Analysis.	Average Number of Times Shown.	No. of Times Shown in 1896 in True Relative Proportion to the Average.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
1	37.6	33	Mrs. Gladstone	1884	Hurst	Pale blush
2	29.3	29	John Walker	1892	Walker	White
3	25.9	30	R. T. Rawlings	1886	Rawlings	Clear yellow
4	25.2	24	William Rawlings	1881	Rawlings	Crimson purple
5	24.4	16	Harry Keith	1886	Keynes	Rosy purple
6	23.0	22	Mrs. Langtry	1885	Keynes	Cream and crimson
7	22.5	21	Colonist	1887	Keynes	Chocolate and fawn
8	20.0	22	Duchess of York	1894	Keynes	Lemon, edged salmon pink
9	19.6	21	J. T. West	1887	Rawlings	Yellow and purple
10	18.3	21	Arthur Rawlings	1892	West	Deep crimson
11	18.0	2	Arthur Ocock	1892	Rawlings	Reddish orange
12	17.7	19	James Cocker	1871	Keynes	Purple
13	16.7	16	Ethel Britton	1880	Keynes	White and purple
14	16.6	16	Maud Fellowes	1889	Fellowes	Pale pink, shaded purple
14	16.6	12	Willie Garratt	1887	Garratt	Bright cardinal
16	16.3	12	Henry Walton	1873	Keynes	Pale yellow and scarlet
17	16.0	18	Duke of Fife	1890	Keynes	Rich cardinal
17	16.0	18	John Hickling	1890	Keynes	Clear bright yellow
19	14.8	14	Mrs. W. Slack	1886	Keynes	Blush white and purple
20	14.7	13	William Powell	1892	West	Primrose yellow
21	13.8	10	Shirley Hibberd	1881	Rawlings	Dark crimson
22	13.4	14	Harrison Weir	1883	Rawlings	Yellow
23	13.1	8	T. J. Saltmarsh	1885	Rawlings	Yellow and chestnut
24	12.4	11	Miss Cannell	1881	Eckford	Cream and crimson
25	12.1	10	Prince of Denmark	1881	Fellowes	Dark maroon
26	10.0	10	George Rawlings	1882	Rawlings	Dark maroon
26	10.0	9	Hon. Mrs. P. Wyndham	1881	Keynes	Pale yellow and rose
26	10.0	10	Majestic	1890	Keynes	White, edged purple
29	9.8	9	Goldfinder	1881	Fellowes	Yellow and red
30	9.0	6	Mrs. D. Saunders	1888	Rawlings	Pale, edged rose
30	9.0	4	Mrs. Morgan	1893	Fellowes	Pale ground, tinted rosy purple
30	9.0*	9	Shotesham Hero	1895	Fellowes	White, tipped and shaded rose
33	8.7	6	Burgundy	1877	Turner	Dark puce
34	8.4	9	Glowworm	1889	Turner	Bright orange scarlet
35	8.3	1	William Keith	1888	West	Dark plum
36	8.2	11	Alice Emily	1890	Keynes	Buff yellow
37	7.8	8	Crimson King	1887	Keynes	Deep crimson scarlet
38	7.6	3	John Standish	1872	Turner	Crimson
39	7.5	11	Earl of Ravensworth	1883	Harkness	Lilac
40	7.3	11	Mr. Glasscock	1886	Rawlings	Purple
40	7.3	4	Prince Bismarck	1879	Fellowes	Puce
40	7.3	11	Queen of the Belgians	1887	Rawlings	Cream and pink
43	7.0*	7	Norma	1894	Turner	Bright orange buff
44	6.9	1	Clara	1879	Rawlings	Rosy peach
44	6.9	2	Joseph Ashby	1879	Turner	Shaded orange
46	6.8	11	Perfection	1889	Fellowes	Orange buff
46	6.8	8	Victor	1887	Keynes	Dark maroon
48	6.4	7	James Vick	1881	Keynes	Purplish maroon
49	6.0*	6	Chieftain	1894	Keynes	Purplish lilac
49	6.0*	6	Kathleen	1893	Turner	Blush

* New varieties, the positions of which are dependent on their records at the 1896 show only.

having been so poorly represented in 1895. Arthur Rawlings rises from No. 13 to No. 10, and at each of the last three exhibitions was better shown than at the previous one. Arthur Ocock (No. 11), although miserably represented in 1896, has good records for the three preceding exhibitions. William Powell (No. 20) loses three places since last year. The only Show Dahlias on the list which were distributed in 1893 are Mrs. Morgan (No. 30) and Kathleen (No. 49). Of the three 1894 varieties Duchess of York already takes up a high position on the table, at No. 8, while Norma will be found at No. 43, and Chieftain at No. 49. Shotesham Hero, which was only sent out in 1895, secures a place at No. 30.

The persistent rivalry for first place in the list of Fancies between Rev. J. B. M. Camm and Mrs. Saunders is still maintained. It may be remembered that the former for the first time in 1895 managed to obtain a slight lead, which it still holds, owing to both varieties having been staged an equal number of times at the last exhibition. Gaiety, for many years the premier flower in this section, now stands at No. 17. It was, however, more frequently staged last year than at any show for six seasons.

Eight new Fancies have, I find, appeared since 1889. T. W. Girdlestone, sent out in 1890, has been shown in a good many stands during the last three years; indeed, for that period only three other Fancy Dahlias have as good a record—viz., Rev. J. B. M. Camm, Mrs. Saunders, and Duchess of Albany. Buffalo Bill, of the same year, has risen from No. 13 to No. 11. Dandy, the only 1891 variety, on its first appearance in the table, takes up its position at No. 16. Comedian, the only representative of 1892, already stands at No. 9. Dazzler, first sent out in 1893, will be found at No. 19; S. Mortimer (1894) at No. 12; Emin Pasha, also of 1894, at No. 14; and Mrs. Mortimer (1894) at No. 19.

The late President of the National Dahlia Society, the Rev. Charles Fellowes, was the raiser of a large number of Show Dahlias, some of which have in their day occupied very prominent positions in these analyses. Prince Bismarck (No. 40), distributed in 1879, is the oldest variety raised by him which finds a place in the present table of Show Dahlias. It was never more largely shown than at the 1883 exhibition, when it occupied the sixth place in the analysis for that year. Since then its decline has been certain, but very gradual. Prince of Denmark (1881) is

another very old favourite. In 1887 it stood at No. 7 in the list. Although now only at No. 25 it still remains the leading flower of its colour—dark maroon. Goldfinder, of the same year, was at one time even more popular, standing fifth in the analysis for five years in succession (1883 to 1887). Of all his flowers, Maud Fellowes (1889), now takes the highest position. The doings of Mrs. Morgan, Shotesham Hero, and Perfection have already been referred to. Mr. Fellowes also raised a good many Fancies, but only one of these, Oracle, has been at any time numerously staged at a Crystal Palace show.

In glancing through the select list of Pompons it cannot fail to be noticed how the best positions are taken up entirely by varieties of recent introduction. In fact, we have to pass over the five leading sorts before we come to any old favourite. Of the older varieties those which maintain their ground best against the new comers are Whisper, E. J. Junker, Darkness, Isabel, and Admiration.

That popular section the Cactus Dahlia is the most modern, and at the same time the one in which the greatest advances have recently been made. Here, again, the most prominent places are occupied by some of the newest sorts, the three leading flowers dating only from 1894. In fact, the only varieties older than these which find places among the first twelve are Bertha Mawley, Robert Cannell, Countess of Gosford, and Juarezi. It is very satisfactory to find Matchless at the head of the list, for it is not only very dependable for exhibition purposes, but has few, if any, rivals as a model Dahlia for ordinary garden cultivation, being of moderate height, very free flowering, and holding its blooms on long wiry stalks well above the foliage.

In the list of Decorative Dahlias the most noteworthy feature is the prominence given to varieties which were only a short time since classed among the true Cactus.

The Singles appear to be somewhat more conservative, for there are still to be found several old friends on the select list. Indeed, as things are going the leading flower Victoria must be regarded as quite an old friend. The fourth place is occupied by James Scobie, followed by W. C. Harvey and Amos Perry, and a little further on by Miss Henshaw. Of these the two youngest were sent out in the same year as Victoria, 1889.

In the following select lists the Pompons have been dealt

FANCY DAHLIAS.

Position in Present Analysis.	Average Number of Times Shown.	No. of Times Shown in 1896 in True Relative Proportion to the Average.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
1	20.1	22	Rev. J. B. M. Camm	1873	Keynes	Yellow and red
2	19.6	22	Mrs. Saunders	1872	Turner	Yellow and white
3	17.4	17	Duchess of Albany	1884	Turner	Orange and crimson
4	16.6	15	Mrs. John Downie	1889	Turner	Orange and scarlet
5	15.0	15	Frank Pearce	1886	Rawlings	Rose, striped crimson
5	15.0	14	Matthew Campbell	1889	Keynes	Buff and crimson
7	13.8	16	T. W. Girdlestone.....	1890	Keynes	Lilac and maroon
8	11.2	9	Dorothy	1888	Keynes	Fawn and maroon
9	10.5	11	Comedian	1892	Keynes	Orange and crimson
10	9.7	9	Peacock	1877	Turner	Maroon and white

14	8.0*	8	Emin Pasha	1894	Keynes	Yellow, striped crimson
15	7.9	5	Henry Eckford	1886	Rawlings	Yellow and red
16	7.0	11	Dandy.....	1891	Keynes	Orange, striped crimson
17	6.6	8	Gaiety.....	1879	Keynes	Yellow, red, and white
18	6.5	2	Professor Fawcett	1881	Keynes	Lilac and brown
19	6.0*	6	Dazzler	1893	Keynes	Yellow, striped scarlet
19	6.0	5	George Barnes	1878	Keynes	Lilac and crimson
19	6.0*	6	Mrs. Mortimer	1894	Mortimer	Yellow and fawn

* New varieties, the positions of which are dependent on their records at the 1896 show only.

with in a similar way to the Shows and Fancies in the tables. In the case of the Cactus, Decorative and Single varieties, however, the average number of times they were staged at the last two shows alone governs their relative positions in the lists. Those marked with an asterisk are new sorts, the positions of which are dependent upon the number of times they were shown at the last exhibition only.

POMPONS.—G. Brinckman, Bacchus, Tommy Keith, Arthur West, Phoebe, Whisper, Nerissa,* E. F. Junker, Captain Boyton, Darkness, Isabel, Admiration, Favourite, White Aster (Guiding Star), Eurydice, Lillian, Sunshine, Mars, Red Indian, and Grace.

CACTUS.—Matchless, Lady Penzance, Gloriosa, Bertha Mawley, Earl of Pembroke,* Mrs. Barnes,* Harmony,* Mrs. Peart,* Robert Cannell, Countess of Gosford, Mrs. Wilson Noble,* Juarezii, Apollo, Beatrice,* Mayor Haskins,* and Mrs. Gordon Sloane.*

DECORATIVE.—Countess of Radnor, St. Catherine, Kynereith, Harry Freeman, Baron Schröder, Black Prince, Mrs. Hawkins, Countess of Pembroke, Josephine, and Millie Scupham.

SINGLES.—Victoria, Phyllis, Demon, James Scobie, W. C. Harvey, The Bride, Alice Seale,* Amos Perry, May Sharpe,* Miss Glasscock, Miss Henshaw, Mrs. Parrott, Northern Star, Rosebank Cardinal,* Duchess of Fife, Miss Roberts, and Mrs. Wythes.—E. M., *Berkhamsted*.

HORTICULTURAL HISTORY NOTES.

ROUND ABOUT MARYLEBONE.

THE populous suburb of Marylebone is generally regarded as one comparing favourably with other suburbs of the British capital. It has some squalid streets, it is true, but on the whole the houses look out upon cheerful thoroughfares; there are numerous small open spaces, and it has a park—largest of the metropolitan parks. One could fancy it has yet traces of its rural days, and memories of the village from which it grew. For some village or hamlet there was in early times here, which had its church—named after the “good Mary,” it has been said; but more likely it tells of the brook which ran along the fields, and near which was St. Mary-on-the-Bourne. With that freedom from precision which characterised old English spelling, this name was often written “Marybone,” or even “Marrowbone.” During the Tudor times it was part of the royal demesne, which extended from Westminster to beyond Hampstead. Afterwards, what is now the Regent’s Park, with other land around, was enclosed as a deer park. At the end of the great Civil War, this Marylebone Park was sold, the timber upon it being reckoned to be worth £1774—about an eighth of the value of the estate—and eventually the ground was thrown open.

To the builder this was not then particularly attractive, and soon Marylebone Fields were taken possession of by the farmers and market gardeners of last century; one of these, mentioned in 1778, was Alsop, whose land lay between Oxford Street and the modern park, where Portman Square and other squares now stand. On the north was Willan’s ground, probably a portion of the park, and other fields westward. Towards Camden Town we read that Arlington Road overlooked in 1814 ground upon which crops were raised for the market. This is now included in the Regent’s Park. The cold nature of the soil acted as a deterrent against the planting of orchards about Marylebone, and even in raising vegetables here and at Paddington the gardeners had to apply enormous quantities of manure. But of Paddington’s 1200 acres only a twelfth was cultivated in 1800, most of the land being grass. Its trees had nearly all disappeared by that time, save a few Elms, Hood’s playful remark on “that bare wood St. John’s” being really true. Yet there once was a wood here belonging to the Knights of St. John. They had another at Highbury, “little St. John’s Wood.” The arrival of inhabitants, and the formation of streets, led to the planting of other trees; nurserymen also found an opening for their business.

One of the older and well-known nurseries of the district was Guy’s Nursery, where a number of men were employed, the present Lord’s Cricket Ground occupies part of the land. Better known still was Jenkins’ Nursery, which had the site now occupied by the Royal Botanic Society’s Gardens, in the inner circle of Regent’s Park. It was established early in this century, Thomas Jenkins making a speciality of American plants; but he had also numerous houses for various exotics, and a portion of the 18 or 20 acres he held was set apart as a botanic garden on a small scale, open by

subscription, and much patronised. This ground was remarkable for having a gentle fall from the centre to the sides; there were trees, fruit and ornamental, though not numerous, and a considerable stock was transferred by this nurseryman to the Society when it took possession in 1840. One of the chief objects before it was to form botanic or ornamental gardens in and about London.

To those who visit these gardens now there are many evidences of the skill shown by Mr. R. Marnock, who was recommended by J. C. Loudon to the Committee, and employed in laying out the grounds. He formed a lake, contrived undulations, and arranged paths, which were so managed as to make the gardens appear extensive; what trees could be worked into the scene advantageously were left, and others planted where required. Sundry changes have been necessary in course of time, but the beauty and variety around us still bear witness to the master hand of the planner. Two specially notable characteristics were—the garden, arranged according to the natural orders, and that illustrating the geographical distribution of plants. The great conservatory, built in 1846 by Decimus Burton, was not completed till 1876. Exhibitions were commenced in 1853, also botanical lectures by Professors Forbes and Henfrey. Amongst the many schemes proposed in celebration of Her Majesty’s long reign I notice that the Royal Botanic Society contemplates the foundation of an Albert Institute of Botany, which is likely to prove a great encouragement to the study of that subject.

Going along the Edgware Road towards Kilburn, on arriving at Maida Hill, some twenty years ago we found ourselves passing a cluster of nurseries, reminding us of what the King’s Road, Chelsea, was in the good old times of George III. Pine Apple Place was suggested by the celebrated Pine Apple Nursery of that locality, long associated with the name of Henderson. There was a period when Pines were grown in the open air by suburban nurserymen, but this was stopped when the increase of houses and factories added so much smoke to the air. The precise date is uncertain; it seems to have been near the end of last century that the nursery was started by Andrew Henderson. His son, E. J. Henderson, opened another nursery in Vine Place, and lived till 1876, dying at the ripe age of ninety-three—one proof that the profession of a gardener is not unhealthy. At both places a good business was done—not only in fruit, but in greenhouse and garden plants—for many years; it used, however, to be a joke that the best Pines came from Vine Place, and the best Grapes from the Pine Apple Nursery. About 1830 a change was made, the nursery in Vine Place being shifted to the Wellington Road. For a short time the Pine Apple Nursery was held by a Company, I believe. Various improvements were carried out twenty years ago, and the establishment became noted for its large collection of ornamental and stove plants. Palms and Ferns were also a speciality here; thousands of such species as *Adiantum farleyense* or *Corypha australis* have been sent out from St. John’s Wood, far and near. Orchids have been grown here, and still are probably in large numbers, the firm having given its name to *Hippeastrum Hendersoni*, a handsome species, raised in unheated pits during the summer, and which flowers freely through the winter months.

Wandering about St. John’s Wood several years ago, I came upon a nursery that was in process of extinction, situate in the Garden Road, near Grove Road, but so placed, being surrounded by lines of houses, that it would have not been easy to find it if a stranger to the locality. It took my attention, because the last possessor had been a Mrs. Ginn, who had apparently figured as a nurseryman before her sex had begun to take up this calling, which now enrols not a few women, and is likely to attract more. No doubt, the dilapidated hothouses and neglected fruit trees have gone and left no trace. One of the older nurseries of Maida Hill was the Clarendon, belonging to Mr. Videon, and another rather extensive was that of Mr. Fairnington, nurseryman and also landscape gardener.

The name of Bayswater has a doubly aquatic sound, and certainly in the olden time it was a place where water abounded. Its springs, rivulets, and ponds were numerous. It even furnished a supply to City conduits, conveyed thither by pipes during the Tudor and Stuart periods. Like other London suburbs, this had its old mansion, Westbourne Place, built in the reign of Henry VI. The garden became noted for its horticultural excellence when in the hands of Jukes Coulson, about the middle of last century. Then, soon after, Bayswater attracted the friends and customers of Sir John Hill; a medico-botanist and quack, some have called him, though really he had great abilities, and wrote upon a great variety of subjects. Loudon admits he helped to spread knowledge concerning the habits and structure of plants; indeed his place at Bayswater was a sort of botanical garden, but he could not make it pay, and at last it degraded into a pleasure ground. Certainly he did puff his balsam of honey, and his essence of Waterdock, produced on the spot, but they may have had good qualities. One

of his rather curious works was a treatise upon raising trees from leaves, another was upon the modes of developing double flowers. His "Eden, a Complete Body of Gardening," was a handsome folio with coloured plates.

People thought themselves fortunate who obtained leave to visit the garden of Comte de Vande at Bayswater, for though the extent was only 2 acres, it had a number of plants representing the Flora of every known country, and a special collection of Roses. One of the oldest nurseries at Bayswater was upon Craven Hill, so named from Lord Craven, who had a mansion in Drury Lane during the seventeenth century, and gave a plot of ground outside London to be used as a "pest field" should the plague break out again. No burials took place there, and after the nursery and market garden had for some years occupied the spot, the last possessors, Hopgood & Co., removed westward about 1844, and houses were built on the slope. Twenty years ago Mr. Burley's establishment at Hereford Road had some remarkable plants, amongst them *Aspidistra punctata*, the purplish flowers of which are developed under the soil, where they usually mature without coming to the daylight. This suburb afforded a home to the illustrious J. C. Loudon during the later years of his life.—J. R. S. C.

SCOPOLIA FLADNICHIANA.

"F. D. B." is perfectly correct in surmising that this plant is comparatively little known or grown. It was, however, exhibited some years ago by Messrs. G. Paul & Son, The Old Nurseries, Cheshunt, and was adjudged an award of merit by the Floral Committee of the Royal Horticultural Society at the Drill Hall. It is rather a robust growing herbaceous plant, with bright green leaves, and pretty bell-shaped pale yellow flowers. This plant seems perfectly hardy on the summit of the rockwork at Cheshunt. It is a Central European plant—Hungarian or Bohemian—and blooming as it does early in March with flowers apparently frost-proof it looks like a valuable addition to the hardy spring flower garden. Fig. 63 represents the flowers and foliage.

HELIOTROPES.

THESE deliciously scented flowers have long been great favourites by all who have a garden, and thousands who cannot boast of a garden plot cherish and tend with assiduous care a few plants in pots. Like the Fuchsia, the Heliotrope when first introduced into this country rapidly became a general favourite. Although the flowers of the original form of *peruvianum* were not particularly showy the odour they emitted was so exquisite that many a gorgeous scentless blossom was rejected for a spray of "Cherry Pie."

As a nation we Britishers are by no means devoid of a love of display, but in the matter of flowers the majority show good taste in considering no blossom perfect, however beautiful it may be, if it lack perfume; but fortunately there are many flowers which are delightful in colour, almost perfect in form, as well as delicious in scent—a combination of good qualities to be found in the Rose. In selecting this for their national emblem, I often think the English showed that marked amount of shrewdness which is generally associated with the canny Scot; but I doubt not that some of our friends across the border will be prepared to stand up as champions of the "Thistle," though perhaps scarcely to claim for it the beauty of the Rose.

It is now the order of the day to utilise a great variety of plants for summer bedding, and those which produce fragrant flowers are perhaps more popular than ever. Heliotropes are well adapted for this style of bedding, and many of the newer varieties have really attractive flowers in shades of colour peculiarly their own. What can be more beautiful in its way than a large bed planted alternately with yellow *Calceolarias* and Heliotrope *Madame Daurel*? I know of no other summer-flowering plant adapted for bedding which produces flowers of so fine a shade of violet blue as does the first-named Heliotrope. Another good method of arrangement is to confine the plants to a single stem till they are about 2 feet in height, then remove the point, which will cause them to branch freely. If these are disposed 3 feet apart in beds, and the groundwork filled in with dwarf yellow *Antirrhinums* or *Calceolarias* an excellent effect is obtained to please the eye, and a delicious odour to gratify the smell. Well-grown standards might also more frequently be used with advantage in the same way that standard *Pelargoniums* are.

When once grown into the requisite size and form they can be easily potted up in the early autumn, and kept as cool as safety permits throughout the winter, to enable them to recoup their energies for another season's work. These are only a few of the

many ways by which the scent of "Cherry Pie" may become more plentiful in our gardens. The chief point to consider now is to provide an ample stock of plants ready for planting out during the first week in June.

Good cuttings inserted now in propagating houses, vineries, or pits will, with proper attention, make good plants by that time. A simple method of propagating is to insert the cuttings in boxes 6 inches in depth. An inch of finely broken crocks placed in the bottom insures ample drainage. Over this place 3 inches of light sandy soil pressed firmly, then dibble in the cuttings, water thoroughly, and cover the boxes with squares of glass. In these close miniature frames the cuttings root quickly, either when placed in full sunshine or in a partially shaded position. Some-

FIG. 63.—SCOPOLIA FLADNICHIANA.

times, however, if too much shade is given the cuttings show a tendency to "damp off." When this state of affairs is discovered the boxes should be at once placed in a sunny position near the glass, or on the hot-water pipes, and no further loss need be feared.

When the cuttings begin to grow the glass must be removed, and a week later each young plant transferred to a 3-inch pot, using a compost of two parts loam and one of leaf soil. Ten days after this operation has been performed the points ought to be removed from those intended for growing in the form of bushes, and a stake placed to others which are to be confined to a single stem. At this season the young plants make rapid progress, and will in the course of a few weeks be ready for a shift into 6-inch pots. At this potting a little refuse from a spent Mushroom bed should be mixed with the soil, which ought to be pressed very firmly, with the object of inducing sturdy growth. In order to obtain good sized plants they should be kept in an intermediate house or vinery till the middle of May and then be gradually hardened by placing them in cold pits. If numbers of old plants in 5 or 6-inch pots are now at command they should be repotted, removing at the same time all but the two strongest shoots, and securing these to a neat stake. Examples of this description will

by bedding out time be found extremely useful for employing as "dot" plants.

In addition to the number required for planting in the open air others should always be grown for the embellishment of the conservatory during the summer and autumn months. It is also a good plan to keep a few large plants in readiness for planting against walls in greenhouses, conservatories, or vineries, as these often supply large quantities of flowers during the spring months, when they are especially welcome for use in a cut state, as well as for the scent they emit in the houses in which they are grown.

The following are all excellent varieties:—Amazon, white, large truss; Bouquet Perfume, lilac blue; Colosse, truss very large, Giganteum, bluish white; Madame Laforce, violet rose, extra good; Madame Daurel, violet rose, dwarf habit; Madame Emma Brouillet, reddish violet, free bloomer; President Garfield, and Swanley Giant, rosy purple.—H. D.

ROUND PIETERMARITZBURG.

I HAVE briefly remarked in a previous article upon the attractions of Nature around the city and district of Pietermaritzburg, Natal, which is surrounded by a lofty range of hills. Maritzburg, as it is usually called for the sake of brevity, is about seventy miles from every other place of importance, and stands 2300 feet above the sea. The population is 10,000. As a rule the city is very quiet, though it is a good all-round place of business. There are three nurserymen and seedsmen who are always ready to supply customers with what they do not require, and there is room for a fourth who understands the trade and will supply the public with what they do require. At present if one send an order of a dozen items, two-thirds of them are sent, and the remainder are substitutes, and not the best of those.

I must not forget to mention the Horticultural Society, which is decaying from the malady known as dry rot. The Society holds three exhibitions every year. I was recently called upon to officiate at the spring show as a judge, and found the plants were very poor. Of course glass is not very extensively used for plant cultivation, as the cost of erection is high; so that most of the plants exhibited were grown on verandahs. The cut flowers on the whole were good, especially the Roses, despite the fact that the weather for a few days previously had been very trying owing to the prevalence of hot winds.

The citizens are well provided for in the way of open spaces. In the centre of the city close to the legislative chamber, post office, fine town hall, and market place, we have some small gardens nicely planted and neatly kept, while at a distance of only a little over half a mile there is a charming park of 100 acres with good cricket and football grounds, golf links, and drives. There are many trees and shrubs, and last, but by no means the least, is the Botanical and Horticultural Society, which numbers Lord Wolseley amongst its distinguished subscribers.

The Society is well supported in various ways by the *élite* of the district. I have taken the following statement of its object from the Natal Directory:—"The object of the Society is the propagation of trees, shrubs, plants, roots, and seeds for distribution throughout the colony; and in furtherance of this object for the purpose of collecting indigenous plants and seeds and exchanging same with kindred societies abroad; also for experimenting on the growth of vegetable products of economic value, and for the accumulation and preservation of trees, shrubs, and flowers of value, beauty, and rarity." The gardens of the Society are charmingly situated in the Zwartkopp valley, nearly two miles from the city, across an expanse of common and through a long avenue called the Mayor's Walk. It would be well for the public if the Mayor and Corporation had to traverse it frequently, as it might induce them to keep it in better order.

The gardens and arboretum are 100 acres in extent. They are well designed and planted, and kept in good order by the supervision of the able and genial Curator, Mr. G. Mitchell, who has during his seven years' tenure of the office made many valuable alterations in them, and introduced numerous trees, shrubs, and plants, of which ten thousand have been sent out this year to subscribers and customers, and many thousands more are being worked up to meet the coming season's demand.

It is a place in which one can always find objects of beauty and interest, and it is difficult to specialise, as there are so many worthy of notice. On entering the gardens by the Curator's residence visitors are attracted by a fine specimen Palm, *Phoenix reclinata*, about 20 feet high, which has been sadly disfigured by the depredations of the locusts. A few of the many other objects worthy of note at this spot are some fine bushes of Gardenias and two Magnolias, about 40 feet high, in full flower. There is the beautiful

Lagenaria Patersoni, which grows into a fine tree here, flowering profusely, the colour being a delicate shot pink; while close by is a splendid *Duranta Plumieri*, with its distinct and pretty blue flowers freely produced for nine months of the year. Planted by its side is the *Reinwartia*, with lovely yellow flowers, and a few bushes of *Azalea indica* of various colours, and a good piece of *Araucaria excelsa*. In the background are some *Bambusas*, and two excellent specimens of *Cupressus macrocarpa* and *C. lusitanica*.

In passing on to the interior of the gardens at every step one sees many interesting specimens of plants, trees, and shrubs, which must be left without comment for fear of being tedious; but there is one of the many which is specially worthy of notice—viz., a fine piece of *Cactus grandiflora* (of the correctness of the name there is a doubt), but anyone who has seen it at sunrise, with scores of its fine brilliant flowers glistening with dewdrops, will have no doubt of its effective beauty.

The next place of interest is a very fine pond, about an acre in extent, surrounded by numbers of fine pyramid bushes of *Camellias* of many shades of colour, with some grand pieces of *Azalea indica* interspersed amongst them. I think it would be impossible to find any more vigorous or floriferous than are these. In the background there are many varieties of handsome foliage trees and flowering shrubs, just at their best a fortnight ago, prominent amongst them being *Hibiscus palustris*, *H. rosea sinensis*, *H. Baptisti*, and the native *H. calycinus*, and *Bocconia frutescens*, with its handsome glossy foliage and fine white bell-shaped flowers; also the pride of India, both red and white, *Lagerstroemia* I think is the right name; *Calystemons*, both red and white; *Plumbagos capensis* and *rosea*; and a *Poinsettia*, which has been in flower for six months.

Oleanders, pink and white, and the *Grevillea*, which I mentioned in some previous notes, its lovely brown and golden orange colour and exquisitely formed flowers cannot be surpassed in floral beauty or elegance. All these are backed by *Coniferae* and lofty Gum Trees, the latter ranging from 100 to 160 feet in height. Amongst the former deserving notice are *Cupressus funebris*, *C. Goveniana*, *Lawsoniana*, *C. sempervirens*, and *Thuia gigantea* and *orientalis*, all these being as good as one could desire to have them. There is also a fine *Musa*.

The Gardens are well patronised by the citizens, and are always open to them free of charge. Most of the things mentioned are not confined to the Gardens, as these and many other good things are largely grown around the neighbourhood, but not so well, as the soil of the Gardens is good, and more congenial to them than any other part of the district.—W. H., November 20th, 1896.

(To be continued.)

ROYAL HORTICULTURAL SOCIETY'S COMMITTEES' AWARDS.

SURELY the logical faculty is altogether wanting in "A. D." He first institutes a comparison wherein the number of awards made by the deputation of the Council of the R.H.S. at the York and Chester Shows is taken as against those made at a series of meetings of the Floral Committees, including those at the Drill Hall, regardless of the obvious difference of the conditions existing in relation to these several shows, of which he seems altogether oblivious. On the other hand, he becomes keenly sensitive to the undoubted difference existent between the York and Chester Shows and that at the Temple, and he asks, "What on earth has the Drill Hall or Chiswick meetings to do with this comparison?"

The answer is obvious. Exactly the same as have the Drill Hall or Chiswick meetings to do with the shows at York and Chester—i.e., nothing. That is the conclusion to which I have been labouring to lead "A. D.'s" mind. But, unfortunately for him, it is completely destructive of his censure of the Council's action at York and Chester, which was the motive of the letter with which he opened the controversy.

The other point must be conceded to "A. D." A blurred impression made "would" look more like "should;" but, accepting the former word as correct, I am pleased to find that "A. D." agrees that the granting of awards has been too free. Whether compelling every member of the Committees to vote would, or would not, tend to a diminution of the number of awards is a question open to discussion; but surely there can be no possible doubt that this result would be achieved by the substitution of a two-thirds for a bare majority.

I do not suggest that if a novelty is submitted which is of sufficient merit, an award should be withheld on account of the number already granted in a particular year. If a new variety deserve recognition it should have it; but I do contend that where so much doubt exists as is indicated by only a bare majority of one in favour of an award, there does not exist sufficient evidence of merit to justify the placing of the *imprimatur* of the Royal Horticultural Society upon the plant in question. Undoubtedly had the "two-thirds" majority been applied in 1896, the number of awards granted in that year would have been considerably and, in the interest of the public who look to the Society for guidance, advantageously diminished.—F. R. H. S.

SPRING NOTES.

WE learn that owing to the Palais de l'Industrie being in course of demolition the next Paris Chrysanthemum Show will be held in the Tuileries Gardens. The show will be opened on Wednesday, the 10th November, and close the following Sunday. Having regard to the great activity in everything relating to the popular flower in France this show should show a decided advance on all previous ones held by the National Horticultural Society, whose headquarters in the Rue de Grenelle have long been insufficient for the purpose.

The French National Chrysanthemum Society has for some reason not been allowed to retain the title "National," and will henceforth be known as the "Société Française des Chrysanthémistes." The sixth number of its monthly Journal is just to hand, by which we learn that there are now 286 members, including nineteen affiliated societies. The annual Conference for 1897 will be held at Orleans, and, like the one held last season at Bourges, bids fair to be an interesting and successful one.

Members of the Northern French Chrysanthemum Society are entitled to receive a copy every month of the Society's official organ, the "Nord Horticole." It is a neatly printed, bright little monthly that has dealt most liberally with the flower for nearly a year past. As evidence of its vitality, and I might add vivacity, it actually blossomed forth into a special double Chrysanthemum number last November, of which I find no mention was made at the time, probably owing to my absence on the Continent. Excellent portraits of Messrs. Calvat, de Reydellet, and Louis Lacroix, with short biographies, were given, and an unparalleled array of Chrysanthemum literary talent was summoned forth by the editor.

Chrysanthemums in Portugal are becoming of some importance there, and a show last November, in the Crystal Palace at Oporto, has already been noticed in a contemporary. M. Henri Cayeux, of Lisbon, the author of the only Portuguese treatise on the popular favourite, was one of the leading prizewinners, and although aware to some extent of the esteem in which it is held in that country, I was scarcely prepared to receive such an imposing catalogue from a trade grower as has recently come to hand. Its size is 12½ inches by 9½, and it consists of nearly sixty pages. The title is "Catalogo-descriptivo dos Chrysanthemos á venda na casa Frederico Daupias." The compiler, like several of his English colleagues, favours us with his portrait, a budget of selections from the press, and about twenty large sized illustrations of Chrysanthemums of different types. It is, indeed, one of the most imposing catalogues, either English or foreign, ever published, but its large size renders it rather unwieldy.

Western King is one of the varieties that was entered in competition for the gold medal of the American Chrysanthemum Society on the occasion of the Jubilee Show of the N.C.S. last November. Mr. Elmer D. Smith has recently sent me a charming photograph of this variety, showing seven beautiful solid-looking blooms arranged in a vase, and, notwithstanding the colour, every petal is shown as perfect and as clearly defined as if one were looking at the actual blooms.

M. Ernest Calvat's new catalogue for 1897 is again a tastefully designed piece of work, and contains several photographic reproductions of his novelties, besides having an inset plate in chromo-lithography of his green-flowered variety called Madame Edmond Roger. If I were asked to make a small selection of his 1897 seedlings I should, judging by the condition in which they were staged at Paris, give the preference to Czarina, Fée du Champsaar, Madame Deis, Madame X. Rey Jouvin, Mlle. Laurence Zélé, Mlle. Lucie Faure, President Nonin, and Surpasse Amiral.

During the present year an international exhibition will be held in Brussels, and in conjunction with it there will be several large flower shows. One for Chrysanthemums will take place on the 6th, 7th, and 8th November next, and schedules have already been issued. Fifty-eight classes are provided, and medals up to £8 in value each are offered for competition. Entries must be made before the 15th October.—C. H. P.

THE CONSERVATORY AT GROVE PARK, KINGSBURY.

AT the seat of W. Walton, Esq., where Mr. Dryden is gardener, the houses for fruit and plants are twelve in number, but my intention is to speak only of the conservatory. It is a lofty old-fashioned structure, with a dead wall on one side, but clothed with living verdure—*Selaginella denticulata*, *Rex Begonias*, *Ficus repens*, and Ferns.

The remarkable feature of this house was that everything had been

brought on in a greenhouse temperature, illustrating what may be done by skill in an inexpensive manner. The pillars and cross bars were festooned with *Tropæolum* Ball of Fire, which added a glow of colour, to be appreciated in the dull days of winter. The centre of the house is set apart for large plants, stages about 3 feet in width along the sides, and a path running entirely round.

Occupying the centre were large specimens of *Dicksonia antarctica*, *Cyathea Smithi*, two semi-double *Camellias*—*Maria Thérèse* (white splashed and mottled with pink) and *conspicua* (bright red); two pyramidal *Azaleas*, a mass of bloom—*Fletcher's White* and *Raphael* (semi-double white); several plants of the hardier Palms—viz., *Phoenix dactylifera* and *Chamærops excelsa*, with a number of large and remarkably healthy plants of *Justicia carnea* and *J. coccinea*, bristling with bloom; a large standard of *Tea Rose Madame de Watteville*, with at least two dozen expanded blooms. Other *Tea Roses* in flower were *The Bride*, *Niphetos*, *Safrano*, *Grace Darling*, and *Perle des Jardins*.

Around the sides of the house were arranged in a light and elegant style several dozens of *Deutzia gracilis*, remarkable for cleanness of growth and profusion of bloom; several plants of *Libonia floribunda* 2 feet high and bushy in proportion, literally covered with bright flower; intermingled were *Blood Red* and *Belvoir Castle Yellow* Wallflowers in 6-inch pots, great bushes a mass of bloom; *Hyacinths* in large pots, so as to make effective masses; *Tulips*, *Polyanthus*, *Narcissi Grand Monarque* and *gloriosa superba*; *Cinerarias*, a strain free from those magenta colours which destroy others; *Primulas* and *Cyclamens*, several fine plants of *Streptosolon Jamesoni*, *Celsia cretica*, autumn sown; and *Carnations* *Madame Arthur Warocque*, the crimson *Malmaison*. In fact, the house was a charm throughout of beauty and fragrance, and was most creditable to the head gardener, Mr. Dryden.—T. STREET.

THE LATE DR. HOGG.

I CAN claim to be one of Dr. Hogg's oldest living acquaintances. It was early in April, 1838, that I went to lodge at Mr. Wheatley's, and Mr. Robert Hogg kindly consented to share his room with me. This was at Brentford End. We had a charming view from the sitting-room (which was over the shop) of all the passers-by. The Queen always went that way to Windsor Castle, and nine mail coaches passed every evening to the West. Mr. Robert Hogg (who was then at Mr. Ronald's) had been lodging there for some time.

It was from there that Mr. Hogg, I, and Miss Wheatley—Mr. Wheatley's daughter—went to witness the procession at the Queen's Coronation. We took our stand in St. James' Street, Piccadilly, on the west side, about half way down, where we had a splendid view of all—I might say perfect—both in going to and returning from the Abbey. I have still a very vivid impression of the Queen's appearance. In going it was a sort of nervous flush; on returning it was that of great fatigue from the long service at the Abbey and from the constant bowing to the cheers of the spectators, for it was almost without intermission from side to side. It was the turning from side to side that made it so wearisome. We stayed to see the illuminations, and it was almost midnight before we got back to Brentford End.

It was while Mr. Hogg was there that he brought home in his large botanist's tin a fine snake, which by some means got out in our bedroom at night. This was rather an exciting experience. The women folk were afraid to enter. The room was searched, as we thought thoroughly, and the snake could not be found. I forget how many days it was before it was discovered; we thought it must have made its escape. One of the women eventually discovered it. I had a very large leather-covered trunk, and under the bottom of this there was a cross-piece of wood near each end, so that the bottom was a little raised from the floor; it was under this that it had got. I forget how we killed it, but Mr. Hogg spent many hours over it getting the flesh off, so as to have a perfect skeleton.

I am not sure of the exact date he left Mr. Ronald's, but some time in the summer of 1838. The then Duke of Devonshire engaged him to make a collection of indigenous plants. I went to Chiswick while this was being done. Mr. Edmonds showed me what he had collected—all potted, standing on coal ashes, all labelled. I did not see anything of Mr. Hogg after this for a long time; but in 1841 or 1842 I went to the Bath September Show and there met with him. I think he told me he was with Mr. Gregory, and travelling for him; but he had begun *Tulip* growing (of course, more as a hobby than as a commercial affair), but he told he had given £90 for a bulb of a variety. He told me the name, but I do not remember it. Yet I do remember that he told that he had got an offset from it which he valued at £30. I joined the British Pomological Society, and, of course, was in communication with him on that account, and I often used to meet with Dr. Hogg at the Council room at South Kensington. I have only been about twice to the Drill Hall.

I omitted to say that some of Mr. Hogg's leisure was spent in writing Latin synonyms. I cannot tell the long lists he would have. One was "*Achillea*," I remember, and such columns as he had searched up astonished me. Many students were making his acquaintance even in these days, young as he was. I remember some gentleman wanted to introduce him to the then Duke of Bedford, who was a botanist. He had written and illustrated a work on the "*Tilia*" as a sort of recreation, so this gentleman told Mr. Hogg. I am a little over a year his senior, that is I am just over eighty. I ought to say that I have ever found him a faithful and devoted friend.—GEORGE LEE, *Clevedon*.

WEATHER IN LONDON.—Bitterly cold have been the winds in London during the past week. The quarter has been north-easterly and easterly throughout the whole of the time until Wednesday morning, when a slight rain fell, and the City in the early hours was enveloped in a dense fog. Towards the time of going to press the fog dispersed, but the rain continued.

WEATHER IN THE NORTH.—Frost ranging from 5° to 9° has been registered every morning during the past week. The wind has been frequently high, generally from the east, and always bitterly cold. Snow has fallen freely in several parts of the country, and altogether the weather has been of a wintry nature. Farm and garden work has, however, been pushed forward after the spell of wet.—B. D., *S. Perthshire*.

CRYSTAL PALACE FRUIT SHOW.—The prize schedule for this show will be issued by the Royal Horticultural Society in a week or ten days' time, and will contain an authoritative list of dessert and cooking Apples and Pears and Plums, post free 1d. Donations towards the prize fund will be gratefully received by the Society.

ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, April 13th, in the Drill Hall, James Street, Victoria Street, Westminster, in connection with which the National Auricula and Primula Society will hold their annual show, 1 to 5 P.M. At three o'clock a lecture on "Artificial Manures" will be given by Mr. J. J. Willis.

VIOLET MADemoisELLE BERTHA BARRON.—A Violet more worthy of cultivation than is given it is Mademoiselle Bertha Barron. It is one of the most hardy double varieties grown, and comes into flower when nearly all other varieties are beginning to get short. I have grown it this last four years in the open borders, and never found it suffer the least from frost. With us it begins to flower the first week in April, and its beautiful dark indigo blue and scent is much appreciated.—E. TROLLOPE. [The flowers sent are particularly rich in colour, but, possibly through packing in moss, lack fragrance.]

THE HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—The last meeting on the syllabus was held on Tuesday, March 30th, when the result of the essay competition was made known. The first and second prizewinners were Mr. F. L. Thurston, Hessewood Gardens, and Mr. M. Skinner, Bishop Burton Gardens, respectively. It was decided to give Mr. R. Greenfield a certificate, his essay being third in order of merit. Five members competed, and great credit is due to each one, they displaying good talent for young gardeners. The chairman (Mr. Chas. Lawton) briefly reviewed the past session, which has been the most successful one both financially and otherwise the Society has ever had. A certificate of merit was awarded Mr. Geo. Picker, gardener to F. R. Pease, Esq., Hessewood, for some splendid blooms of *Amaryllis*, of which the seeds were sown three years ago, which for size and colour would be hard to beat. The annual dinner was announced for April 14th.—F. L. T.

ISLE OF WIGHT.—The monthly meeting of the Isle of Wight Horticultural Improvement Association was held at Newport on Saturday last. During the afternoon and evening there was an exhibition of Narcissi and other spring flowers. Messrs. Barr & Sons of London staged a magnificent collection of Daffodils and Tulips, numbering about 150 bunches in all, which were effectively arranged, the monotony being relieved by Palms and Maidenhair Ferns. Mr. A. E. Cave of Newport Nurseries staged a group of plants, including Azaleas, Orchids, Ferns, and Palms. In the evening Mr. T. W. Birkenshaw's paper on Daffodils was read by the Secretary. In the subsequent discussion which followed it was agreed that the exhibition would give an impetus to hurb culture in the Isle of Wight which in many places might prove of commercial value if capital, labour, and knowledge were applied. The Association, under the chairmanship of Dr. J. Groves, F.G.S., is endeavouring to create a greater interest in horticulture in the Garden Isle, and no doubt this, the first spring show ever held in the island, will be a means to accomplish this object.—S. H.

THE DAVID THOMSON TESTIMONIAL.—The subscription lists for Mr. Thomson's testimonial will close on May 1st, and it is hoped all who intend to join will send in their subscription by the above date.

GARDENING APPOINTMENT.—Mr. Maurice Jones, late gardener to Baron Von Roemer, Lime Park, Hurstmonceux, Sussex, has been appointed head gardener to W. Cooper, Esq., Cockley Cley Hall, Swaffham, Norfolk.

CYCLAMENS AT LUTON HOO.—A few weeks ago I had the pleasure of visiting Mr. G. H. Maycock at Luton Hoo Park, and was particularly struck with the collection of Cyclamens. The plants were in 48-pots, and had been raised from seeds sown about twelve months previously, and the manner in which they were blooming spoke volumes both for the excellence of the culture and the strain of seeds (Sutton's). In all there were about 1000 plants, and there was not an inferior one in the whole number. It is gratifying to see how Cyclamen growing is both improving and increasing, though such collections as the one noted are still by too seldom met.—TRAVELLER.

DEATH OF MONS. G. VILLE.—We learn with regret that Mons. Georges Ville, the eminent authority on chemical manures, died on the 22nd February, in his seventy-fourth year. He carried out a series of agricultural experiments in the trial ground of Vincennes, Paris, as long ago as 1867, and published a book entitled "Les Engrais Chimiques," in 1868. It has passed through seven editions at least, the seventh appearing in 1890, and has been translated into Italian, German, Polish, Russian, Spanish, Portuguese, and English, a translation being also made in the United States of America. The principles he taught, or the views which he expounded have been generally accepted, and are advocated at the present day, including those relating to the fixation of the free nitrogen of the atmosphere by the bacteria in the nodules of the roots of leguminous plants.

WAKEFIELD PAXTON SOCIETY.—At the ordinary weekly meeting of the members of this Society, held Saturday evening, March 27th, Mr. W. H. Milnes of Green House, St. John's, presided, and Mr. W. Tunnicliffe of the Poplars, Thornes, occupied the vice-chair. There was a good attendance. The lecturer was Mr. G. H. Goldsborough of the Wakefield Asylum, and he delivered a lengthy and exceedingly interesting lecture on "Swaledale," illustrated by a large number of beautiful photographic slides, which was cleverly thrown on the screen by Mr. Harold Parkin, lanternist to the Society. Mr. Goldsborough, who appears to be thoroughly acquainted with the Yorkshire dales, and is also a naturalist and antiquarian, gave his audience much historical information, and related many interesting incidents in connection with Swaledale, its castles, mansions, rivers, waterfalls, and woods.

THE CARSHALTON, BEDDINGTON, AND WALLINGTON HORTICULTURAL SOCIETY.—An interesting ceremony took place on the occasion of the anniversary dinner of this prosperous Society, which was held in the Public Hall, Carshalton, on the evening of the 31st ult. Mr. H. Cosmo Bonsor, M.P., presided, and was supported by Mr. E. J. Halsey, Chairman of the Surrey County Council; Mr. A. H. Smee, C.C., a great patron of county horticulture as practised so successfully by the operative classes; Mr. H. Macan, M.A., Secretary of the Technical Education Committee, and many other gentlemen, including representatives of the District and Parish Councils. The workers also attended in goodly numbers, the assemblage comprising some 150 persons. Excellent speeches were delivered by the Chairman, Mr. Halsey, and others, the last named gentleman presenting the silver Banksian medal to Mr. Harvey Hopkins, as not only the champion allotment holder of the district, but of the county of Surrey; and right well he deserved the honour in view of his splendid work, carefully appraised during the last three years. It was remarked during the evening that this was the first occasion that the Banksian medal had been granted to any individual allotment holder, and it is bound to have a stimulating effect. If the Council of the R.H.S. (which seems anxious to do all the good possible should grant a similar medal another year, the Committee of this prosperous local Society (of which Mr. G. W. Cummins is the efficient Honorary Secretary) may perhaps consider the advisability of granting it to the champion cottage gardener in the district. It was stated during the evening that the immediate effect of a conference held in connection with one of the shows of this Society on August 3rd, 1891, was the formulation of a syllabus for the teaching of horticulture in schools, which was adopted by the Education Department, and the meeting was also the pioneer of teaching practical horticulture by the County Council, which teaching has now extended over the greater part of the kingdom.

— WEATHER IN NORTH BEDFORDSHIRE.—Here in North Beds 9° of frost was registered on the morning of Tuesday, March 30th. April, instead of warm showers, was ushered in by a fall of snow sufficient to clothe the Conifers and new mown verdure in wintry attire. On the 5th 7° of frost was registered.—H. T.

— MARCH WEATHER AT DRIFFIELD.—Mean temperature at 9 A.M. (corrected), 42·37°. Wet bulb, 40·29°. Mean maximum, 48·29°. Mean minimum, 36·8°. Highest, 57·6° on the 21st; lowest, 25·4° on the 30th. Mean of maxima and minima, 42·54°. Mean radiation temperature on the grass, 30·8°. Lowest, 18·6° on the 2nd. Rainfall, 3·41 inches. Number of rainy days, twenty-one. Greatest amount on one day, 0·58 on the 2nd.—W. E. LOVEL, *Observer, York Road, Driffeld.*

— MARCH WEATHER AT HODSOCK PRIORY, WORKSOP.—Mean temperature, 44·5°. Maximum in the screen, 61·8°; minimum in the screen, 23·5°; minimum on the grass, 13·5° on the 30th. Number of frosts in the shade, five; on the grass, fifteen. Sunshine, 95 hours, or 26 per cent. of the possible duration. Rainfall, 2·44 inches; rain fell on eighteen days. A very warm month, similar to last year, but with more rain. Excess rain since January 1st, 2·7 inches. First swallow on 31st.—J. MALLENDER.

— WEATHER AT DOWLAIS.—The following is a summary of the weather here for the past month:—Total rainfall, 7·87 inches, which fell on twenty-six days, with a maximum of 1·32 inch on the 2nd. There was a sharp snowstorm on the 3rd. Mean maximum temperature, 48·1°; minimum, 33·7°; highest reading, 63° on the 23rd; lowest, 22° on the 29th. The wind was in the S.W. and W. on seventeen days, and in the N. and N.W. on seven days. There were seven sunless days. A very rough month, with strong winds the most of the time, often blowing quite a gale. Heavy thunder and strong lightning on the 4th and 16th and 17th.—WM. MABBOTT, *Dowlais, Glam.*

— SUSSEX RAINFALL.—The total rainfall for March at Abbots Leigh, Hayward's Heath, Sussex, was 5·09 inches, the heaviest March rainfall in sixteen years, being 3·01 inches above the average. Total for the three months, 10·45 inches; 3·79 inches above the average. The heaviest fall was 0·89 inch on the 2nd. Rain fell on nineteen days. The maximum temperature was 60° on the 21st; the minimum 28° on the 30th; mean maximum, 51·04°; mean minimum, 38°; mean temperature, 44·52°, which is 3° above the average. A wet and stormy month. Not till the third week was it possible to go on the land to get crops in; since then it has been fairly dry and workable. The 1st of April was extremely wet and cold, with sleet at mid-day. A thunderstorm occurred on the 31st with heavy showers. Vegetation is forward for the season.—R. I.

— HARDY BULB CULTURE IN ENGLAND.—I note on page 268 of your last issue that your correspondent "G. H. H." says I recommend it "as a means of pulling the British farmer out of the quagmire of agricultural depression." This was not, however, my object, for bulb culture, in order to make it a pecuniary success, requires far more intimate technical knowledge than most British farmers possess. Bulb culture is a special thing, and requires special knowledge, as well as a most suitable soil and climate, or the results may be as disastrous in this as in other special systems of cropping the land. Again, a knowledge of the best markets is as essential as production of a good sound article, even although flowers and bulbs do in a sense advertise themselves if seen by those who want them. Now and then a farmer might grow a few bulbs with profit, but it is by no means likely to be a crop likely to benefit farmers generally.—F. W. B.

— THE HORTICULTURAL TRADE OF THE ISLAND OF BUTE.—On Tuesday, the 23rd ult., the Marquis of Bute, the Provost of Rothesay, opened a new post office in that town. Hon. Sheriff Mackirdy, in his speech at the opening banquet, thus referred to the gardening industry carried on in Rothesay and neighbourhood:—"The only considerable trade now is the trade of market gardening and the raising of seeds and plants. Coincident with the decay of other trades he had mentioned, they had this very important trade rising up amongst them. Without making any invidious comparisons, he might mention that of the dozen or so firms engaged, one—that of Messrs. Dobbie & Co.—had risen to a very important position in regard to the trade of the kingdom in its own department. In one year they had sent out no fewer than 140,000 parcels, &c., through the post office, at a cost of £1500 for postage alone. It was a trade which seemed to suit the genius of Rothesay, and they proved it by carrying on a business which depended so much on geniality of weather and good soil."

— ABERDEEN.—An association is being formed, at the instance of the General Council of the University of Aberdeen, for the purpose of diffusing information regarding the wants of the University, and of collecting funds, and applying the same to purposes tending to promote its efficiency as a seat of learning. In the enumeration of the more pressing wants of the University, the second place is given to "a botanic garden, and funds for its maintenance;" and among the lectureships suggested, "forestry" holds a good place. Already a large and influential number of gentlemen have become members of the Association, and the names are still coming in. It is sincerely to be hoped, says a contemporary, that Dr. James W. H. Trail, Professor of Botany in the University, will soon have one of his pet schemes carried out—the establishment of a botanic garden.

— JAPANESE BAMBOO.—Bamboo and bamboo wares constitute an important item in the miscellaneous export commerce of Japan. Bamboo for shipment abroad is grown in several districts, the varieties differing somewhat according to localities. In Hiroshima the black and the spotted varieties grow; the former is produced in Kochi. Bamboo grown in Yamaguchi, Oita, and Ehime belong to the cheap varieties. The cultivation of black Bamboo is carried on extensively in Kochi, where a tan (a quarter of an acre) of Bamboo yields 30 to 60 yen per year. Bamboo is exported to most countries of Europe, and also to America and Australia. The bulk of the Bamboo shipped from Kobe—from which place nine-tenths of the total are imported—goes to England, the varieties being black, spotted, and white. To France and Germany the black and white sorts of the best quality are shipped; while long, bleached, angling Bamboos are in demand in New York.—("Journal of the Society of Arts.")

DEATH OF MR. W. G. HEAD.

AFTER a long period of suffering, often of the most acute character, Mr. Head, who was for eighteen years Garden Superintendent at the Crystal Palace, sank to rest on Saturday last. Though the deceased had been unwell for a considerable time before other than his most intimate friends were aware of the fact, the serious nature of his complaint became evident to those who travelled with him from the Shrewsbury Show last August.

Shortly after that event it was found by the highest medical authorities that Mr. Head's life could only be prolonged by a serious, delicate, and dangerous surgical operation. This was performed, and it has been little short of a marvel that he survived so long.

The late Mr. Head was a genuine gardener. He was born at Worthing in 1837, his father being then a small nurseryman there. In due time young Head was apprenticed to Mr. McEwen, who was gardener to the Duke of Norfolk at Arundel Castle, and subsequently became Superintendent of the R.H.S. Gardens, Chiswick. From Arundel the young student went to Shrubland Park, succeeding Mr. A. F. Barron there, who also went from Arundel. Mr. Head passed to Drumlanrig, where we think he became foreman. He subsequently served in the gardens at Castle Dykes, then at Abernarr in South Wales, and was eventually appointed plant foreman at Chiswick at the time when many plants were required for the conservatory at South Kensington.

From Chiswick he went to Kew, where he was employed in a similar capacity, and from there was sent to make and plant the gardens of the Agri-Horticultural Society of Calcutta at Alipore. He was in India about seven years, and soon after his return to England Mr. G. Thomson resigned his position at the Crystal Palace, Mr. Head being appointed his successor in 1879.

At that time it had become necessary to reduce the expenditure in the garden and pleasure grounds, and Mr. Head was just the man for the emergency. Active, zealous, and industrious, he determined to make the best of the means at his disposal. He worked like a Trojan, and others had to work too, or they were not made happy. He had tons of effete soil removed from the borders in the Palace and fresh brought in; then soon after the plants and trees showed the effects of it in invigorated growth. A gas-light exhibition held in the transept undid all the good he had done and more, for it spoiled the appearance of the noble building for years. Still, Mr. Head did not sit down and grieve, but worked on undaunted to make the best of the position.

His activity at flower shows was well known to many. He did not march about with a wand and direct, but often did as much work as two or three men in moving and arranging the exhibits to produce the best general effect; and when he was very busy it was well not to ask him trivial questions, as he would only have time for short replies, almost incapable of being misunderstood.

The late Mr. Head was a man of energy—of work, but had a warm heart, and was a ready helper in causes of charity and cases of misfortune that came to his notice. He was a quick and excellent judge, highly respected, and was the recipient of a presentation a few years ago, while everything that could be done for him during his period of suffering was done most readily by those who knew him best.

We hear the remains of Mr. Head were interred yesterday—Wednesday, the 7th inst.—at Chiswick.

DENDROBIUM NOBILE.

THERE have appeared in several papers of late references to some magnificent *Dendrobiums* grown by Mr. Moreby, and we now present our readers with a photographic illustration of one of these, with an interesting note relative to them from Mr. R. Scott. Our correspondent says, "I lately saw some splendid *Dendrobium nobile*, grown by Mr. William Moreby, gardener to Mrs. Knowles, Moorhead, Shipley, Yorks. There were four plants, nearly equal to the enclosed photograph. This one measured 5 feet by 3, carrying 1134 splendid blooms, growing in a 16-inch basket. When Mr. Moreby took charge of this place, about five years ago, these plants were small and in very bad condition, but under his care they have made great progress, and are now fine samples of good culture. Many other things are well done in this small but well kept garden—notably *Chrysanthemums*. In fact Mr. Moreby is one of these good all-round men."

PRECEPT AND PRACTICE.

(Continued from page 227.)

APPROACHING now the higher phases of gardening, it may be thought that a very high jump as well as a long one has been made; yet I think that there is no young traveller on our road who should not look down its long perspective as far as possible and be prepared accordingly for all possibilities, and also be early and deeply impressed with the power it is his prerogative to wield if developed. If developed, I may repeat, for it is scarcely probable that any young man who aspires to be a gardener in the fullest sense of the word can be devoid of that inherent power which may—which should—place him upon a high pedestal. That he may be unaware of it is another matter, for until we are called upon to exercise our strength we know it not, nor consequently our weakness. "But," some young critic may inquire, "are we—gardeners of the future—to be landscape gardeners?" Well, you may or may not be called upon as an author in this direction, but you infringe no law of copyright in studying and understanding these advanced chapters of the work; moreover, there are very good reasons why it should be done, and done now.

Who, may I ask, should be able to interpret this great work of Nature and Art if not the gardener? The gardener; from hence I would that our homely title should be fully invested with its comprehensive responsibility. That there are gardeners and gardeners goes without saying. We have on the one hand the "good all-round man," which is to my mind something of a misnomer, being as it were a kind of circular perfection easier to find in theory than in practice. On the other, and relevant to this, are those great masters of natural harmony—those eminent landscape gardeners—to whom we may be only called upon to play second fiddle. Can we do so intelligently without a knowledge of the higher notes we are expected to chord with? By whom have we—gardeners—been oftener weighed in the balance and found wanting than by these highest exponents of the art? By none, for there is none so competent to judge, or so apt to judge, as those who have made it a life's study, and more than once have I writhed under their scathing criticism in print, but acknowledged its justness.

The chief end and aim of life will often appear, from a bothy point of view, to be that of a successful cultivator, which, of course, one must be, but more also, to be a gardener—a gardener as I understand it. Goethe said, "The beautiful is a manifestation of the secret laws of Nature." It should be our constant endeavour, our high aspiration to understand these laws, to wrest the secrets from the master hand. The continual exercise of our faculties in a right direction must lead us upwards and onwards to an accurate conception of that beauty which is the soul of inspiration—inspiration in our work. The simplest and perhaps the highest form of that work is rather to make manifest such beauty as we have than the slavish reproduction in fac-simile of scenes and objects possibly far removed. Imitation of Nature often, somehow, fails to catch the spirit of the thing contemplated, and leaves us after all our labours with what bears indubitably upon its face the word "sham."

Our first study in this direction may be made upon strictly utilitarian lines, where more than elsewhere, if possible, pretence

should have no place. Looking back upon a garden where two years of early life were spent, its perfect arrangements stand out so clear, that it may well serve to illustrate this part of the text. Taking it all in all, it was the best type of its kind for the purpose, and the satisfying impression that it then afforded was so indelibly fixed, that it would be easy now to reproduce from memory alone an accurate plan; easier, perhaps, as it then afforded me my first practice in scale drawing. May I suggest to our young draughtsmen that they should, as they flit from garden to garden, carry away with them neatly executed plans of their temporary spheres of duty, and they might well be retained by interleaving them in the diary, which they would worthily illustrate.

The character of this garden—and gardens are possessed of individuality as much as gardeners are—might be summed up as being that of severe simplicity. A kitchen garden in the broadest sense—viz., a garden for the supply of high-class vegetables, fruits, and flowers for cutting—it was admirably adapted to its purpose, but I doubt if the extensive, well-planned, and well-kept pleasure grounds, from which it was isolated, ever afforded more pleasure to the critical eye. However, comparison would be invidious, for they are distinct types, and the importance of the latter will be considered in due course. We will choose by preference to begin nearer home—nearer to the bothy, which should be the first spot from which to focus observation. Situated on a gentle slope to the south the position had been utilised to form a terrace, one-half of the garden being raised some feet above the lower division, and the wall between the two on the sunny and deeper side was covered in with a lean-to range of fruit houses, the principal lean-to range with its projecting span-roofed houses occupying a position near the entrance to the garden in its lower division. The manner in which the whole area was divided by handsome walks, affording facility for the heavy work in its annual course to be carried on with the least evidence of confusion, and from a general survey of all within the walls the conclusion might justly be arrived at that it was an *edition de luxe* of a kitchen garden; and it was not until one analysed in detail its many parts that the severe simplicity of its lines became apparent. Houses, offices, fruit and vegetable quarters, flower borders, all bore that impress, yet all bespoke the skill which had planned the best for the purpose and placed each exactly where it should be. The chief object in its minute details had in no instance been sacrificed to appearance, and the facility given for high-class gardening which was carried out formed an ideal seldom met with—seldom met with, and that owing probably to circumstances which few can control; but we must have ideals in our lives to work up to, and those who have the clearest conception of them are in a fair way to attain them.

Important and useful as are good general ideas of the above utilitarian part of our subject, it is outside the garden proper a wide field stretches for investigation, and here too are sub-subjects, over which grave errors may arise, from false notions of what constitutes lines of beauty. Examples may be met with in which the one aim appears to have been a predominating anxiety to obliterate all natural landmarks, and replace them by an unstinted expenditure with artificiality. This does not arise from mediocrity or a paucity of ideas, but rather from a superfluity, which swamps simplicity and purity of design. It is as if our harmony could only be executed by the introduction of numerous arpeggios and stumbling staccato passages. As a rule gardeners are seldom called upon to bear the burden, or the sins if such obtain, of designing in contiguity to the castle or mansion. It is a kind of sanctified ground, upon which the architect and landscape gardener meet to blend their several ideas, in order to suitably frame what may range from stately magnificence to the simply pretty picture—from a Trentham or a Chatsworth to a modern villa.

What! Expect our lads of the bothy to understand these things upon the larger scale? Certainly; grasp the meaning now, that you may hereafter be competent to judge of the fitness of things to their purpose, and eventually qualified to form, and to give if necessary, a correct opinion. All such works of art are of course, or should be, a part and parcel of the building, that being here the chief object; but stretching away from this we must keep in sight the near or distant relationship of the multitudinous parts which go to form the beau ideal from whatever standpoint we view it.

Carriage roads, drives, avenues, and paths are very visible lines in the geography of most domains or localities. Possibly we may here learn more from noticing errors, and very probably too our young men may sooner or later be called upon, when taking up a responsible position, to rectify some of them. Such occasions are nearly certain to arise; the trained eye will look for them—welcome them. Outlines on this subject will occupy our next paper with the hope that they may eventually help some to "Take occasion by the hand, and make the bounds of freedom wider yet."

—AN OLD BOY.

(To be continued.)

VIOLAS—SEEDLINGS VERSUS CUTTINGS.

OF the great value of these popular flowers for both spring and summer bedding I need say but little, for they are already firmly established as favourites in gardens innumerable throughout the length and breadth of the land. The cry is no longer heard that they are only adapted for northern gardens during the summer months, for good culture has shown that even in the sunny south few bedding plants give a finer display during June and July than do Violas. It has long been the practice to raise the requisite number of plants for this purpose by inserting cuttings in August and September, and for producing good plants for flowering during the months named I have found no plan to surpass this time-honoured one. Violas are, however, indispensable for spring bedding, and in the majority of gardens where this is a feature it is important to have the beds bright and attractive throughout April and May.

by cuttings. In some instances we find this a drawback, because strong growth is made at the expense of floriferousness, but such is not the case with Violas. If we can only secure early growth we may confidently anticipate abundance of flowers.

When planting a geometrical garden it is often a matter of necessity to have each bed or group of beds filled with flowers of the same colour, because such an arrangement meets with great approval at headquarters, and some may perhaps urge with considerable force that for this reason seedlings are not suitable for the purpose because they cannot be depended upon to come quite true to colour. This difficulty, however, almost entirely disappears if seed is purchased from reliable firms who are already noted for their fine strains of bedding Violas in separate colours. These may be obtained in the following shades of colour:—White, yellow, violet, purple, blue, and mauve. Often not more than 5 per cent. of the plants grown from this seed fail to come true to colour.

FIG. 64—A FINE DENDROBIUM NOBILE.

When we are fortunate enough to get fine autumns and mild winters Violas raised from cuttings will often flower well during April, but this is rather the exception than the rule, this season, at any rate, judging by the present appearance of plants raised from cuttings inserted last August, they will make little show till the first week in May (I am writing from the Midlands) here. Here, then, is a little difficulty which needs to be overcome, and fortunately I am able to state the way to do it. It is simply by growing seedling plants in all instances where the chief display is required during April and May. At the present time we have beds of seedlings which are flowering freely, while others occupied by cutting-raised plants show only a few half-opened flowers.

Seedlings are, as a matter of course, more vigorous, have more active roots, and are in consequence able to withstand the cold of winter better. They seem to start away at once as soon as we get spring-like weather, whereas in the case of plants raised from cuttings a late start is made, and even then progress is slower than with seedling plants. If we frequently obtained cuttings from other localities I have no doubt that some improvement would take place; still the fact remains that in almost any genus of plants seedlings are more vigorous than those raised

I find the first week in July early enough to sow the seed; this is done either in boxes or on a shady border, and when the young plants are large enough they are transplanted 6 inches apart on borders in the reserve garden. By giving them this ample distance sturdy growth is assured, and weeds can be easily kept down. Should the autumn prove mild, by the time the beds in the flower garden are ready to receive them (which is generally about the end of October) many of the plants will be in flower. It is then an easy matter to select only those that are true to colour. When flower gardens are situated in very bleak positions it is a good plan to defer the planting till March or early in April; the plants can then be lifted with good balls of earth, and with care in planting will scarcely experience a check, and are often in full flower before those planted out in the autumn, when such have been in a bleak situation throughout the winter.

Beds of seedlings should at this season be watched daily, and as soon as a "rogue" is detected remove it at once to the mixed border, and fill up the vacancy with a selected plant true to colour. By attending to these trifling details no one need have the slightest hesitation in using seedling Violas for bedding purposes, and I feel sure that those who, like myself, have found plants raised from cuttings a trifle too late in flower-

ing for spring gardening, may find a way out of their difficulty by adopting the plan above given.

Although Pansies and Violas are now grown in enormous numbers, it seems to me that there is a still greater future before them, as they give such a wealth of flower compared with the little trouble their culture entails.—FLOWER GARDENER.

SPRING IN LONDON.

WHERE are we to look for the signs of spring in the great metropolis? You may find them in park, in garden, in disused burial ground, and other open spaces. Thanks to the County Council and the authorities of the Royal parks, many places where children play and adults walk for recreation are made beautiful by the display of bulbous flowers.

The Embankment gardens are now gay with Hyacinths and Daffodils, the grass looks green and inviting, and the trees will soon be in full leafage. During the dinner hour at midday the Strand and Fleet Street pour forth their living mass of workmen who hie to the Embankment gardens for a breath of fresh air and a peep at the flowers. The gardens make a pleasing frontage to the great hotels and other buildings which fringe the bank of the silent river, and bright patches of colour are everywhere conspicuous. The combinations are well blended, and at one point the smoke-blackened statue of the poet Burns looks down on a circular bed of white Hyacinths, surrounded by triangles alternately blue and red. Inside the gates near Charing Cross patches of mixed Hyacinths look effective on the banks, and in such positions this seems to be a good method of planting.

In spite of the never-ceasing roll of traffic which passes to and fro through Parliament Square, the carefully tended and strongly guarded portions of greensward and flower beds have quite a spring-like appearance. Standing in full view of the seat of their labours are the figures of Lords Palmerston, Derby, and Beaconsfield, with Sir Robert Peel, and round them are large masses of the white Hyacinth *alba maxima*, pink Gertrude, and blues Chas. Dickens and Lord Derby. It is a redeeming feature to see something natural amid so much that is artificial, and from the tops of 'buses people catch the sweet aroma which rises from the beds, and crane their necks to get a peep at the flowers. The grass in Parliament Square always looks well, and though yet early the emerald green contrasts pleasingly with the bright tints of the flowers. No other signs of Nature are apparent, unless it be the house sparrows which hop fearlessly about as though the enclosures belonged exclusively to them.

In St. James' Park one looks in vain for large masses of flowers, as here the scarcity of beds render such mode of planting impracticable. Nor are such required. The patches of Hyacinths and Tulips on the banks and edges of the shrubberies are quite in character with the surroundings. Dying foliage in the grass tell where Crocuses have been gay, and their place now is admirably taken by Daffodils. The pink blossoms of *Megasea crassifolia* are noticed here and there, and Wallflowers are rapidly adding their share to the combination of blossom and bursting foliage. Overlooked from the windows of Buckingham Palace is the Green Park, the gentle slopes of which in their mantle of verdure truly merit the name.

Entering into Hyde Park at the Stanhope Gate, and turning through the flower garden, one is met with a panorama of colour as brilliant as it is bewildering. Perhaps some of the individual spikes of Hyacinths are not so fine as in previous seasons, but on the whole the show is up to the standard, and visitors to London during the next few weeks will do well not to miss it. The admirable blending of colours foretells foresight and good taste, and for variety it is hard to say whether any of the fashion shops in Regent Street could produce anything equal to it. One does not often in private gardens see Daffodils and Hyacinths mixed, yet what a charming combination they make! In Hyde Park *Narcissus princeps* is blended with Hyacinth *alba maxima*, and a little further on the massive foliage and opening blossoms of *N. Emperor* make a charming contrast to the white and blue Hyacinths. In another bed Hyacinth Mont Blanc and *N. rugilobus* are combined and surrounded by a double row of *H. Charles Dickens*. Other varieties are planted *en masse*, and amongst the most conspicuous are the light blue spikes of *Couronne de Celle*, *Orondates*, dark blue, with such well-known kinds as Lord Derby, General Havelock, Czar Peter, and La Grandesse.

Not the least conspicuous are the beds of *Narcissi*, though it is questionable whether they are not more pleasing when planted in conjunction with Hyacinths. Sir Watkin maintains its well-deserved reputation for floriferousness, and indeed is charming. Just a mention of *N. Golden Spur*, *Horsfieldi*, and *maximus*, which give variety, and show beyond argument how indispensable in a collection of spring bulbous flowers is the nodding Daffodil. Tulips will be all aglow when Hyacinths are on the wane, and thus the show is prolonged. Some of the most forward are already showing bloom, particularly *Keizers Kroon*, which is planted in large masses. Other beds are filled with *Canary-bird*, *Joost van Vondel*, *Duke of York*, and varieties of equal standard. Little blue *Scillas*, *Daisies*, and *Wallflowers* all add their share, and interesting are the remarks passed by the varying sorts and conditions of men and women who perambulate daily between the Stanhope Gate and the Marble Arch.

Regent's Park, ever famous for its Zoological and Botanical Gardens, its avenues of giant forest trees, and delightful walks, has now another feature of more than passing interest—its spring flowers. The authorities by judicious planting and careful arrangement have created a reputation in this direction, and this season's display bids fair to maintain it. Hyacinths are all aglow, as soon will be the Tulips, Wallflowers and

Doronicums. The long lines of Horse Chestnuts are rapidly putting on their mantle of green, and will look all the brighter ere their growth becomes sullied, as soon it must do, amid the grimy surroundings. One does not have to go quite close to see that the circle masses of gold are caused by the tall flowers of *N. Horsfieldi* and *N. Sir Watkin*. It is possible to notice a few diversions from previous years, one of these being the planting of several large beds with mixed Hyacinths. The effect is pleasing, and is rendered more so from the fact that the surface is undulating, this doing away with the flatness that is sometimes complained of. Along the narrow borders that run the length of the garden Hyacinths are dispersed in miniature triangles, Robert Steiger being particularly fine. *Narcissus Emperor* and *Wallflowers* make a pleasing combination in a large three-cornered bed, and a similar area is devoted to the telling flowers of *Tulip Keizers Kroon*. Among other beds of Hyacinths planted *en masse* it is easy to discriminate the light blue of Lord Derby and the pink of Gertrude.

To the lover of mixtures the banks and slopes will have a particular interest. These Hyacinths, Daffodils, Tulips, *Scillas*, and the like are vieing with each other for prominence, and dispersed without any attempt at classification in that easy natural way which gives such favour to this mode of planting. Every adaptable position is beautified, or will be in due course, as many flowers have yet to unfold. Pink *Megaseas* are telling of their presence here and there, and the permanent Daffodils in the grass nod gracefully in the sunlight. As one turns from the masses in the flower beds to these seemingly wild breadths which stretch over the carpet of green one is undecided which makes the more pleasing picture; both have their bright features. So much for the spring flowers in the heart of the great city; but what of those that adorn the County Council parks, and lie dotted about in the outer radius! Space forbids mention of them here, but they shall form the subject of future notes.—G. H. H.

BERWICK HALL.

BERWICK HALL, Shrewsbury, the seat of W. G. Phillips, Esq., is a charming residence, elevated upon terraces overlooking the Severn, and a lovely span of country backed by hills clothed with fine woods. It is surrounded with beautiful gardens and extensive pleasure grounds, making it a delightful home, and a most pleasant place to visit.

Mr. Bradley, from the Wergs Hall Gardens; Mr. Simpson, The Mount Gardens; and myself, spent a very enjoyable day in looking over the grounds inspecting the grand collection of *Dendrobiums* and other Orchids. Several hundreds of the former were arranged in the flowering house ready for the photographer, and it was glorious sight. All lovers of Orchids will be able to judge when I tell them what varieties were displayed there. Below are a number of varieties that were noticed:—*Dendrobium nobile*, *densiflorum*, *Wardianum*, *W. candidum*, *W. giganteum*, *D. Farmeri*, *thysiflorum*, *pulchellum*, *Pierardi*, *Parishi*, *nobile nobilium*, *N. intermedium*, *formosum giganteum*, *Findleyanum*, *fimbriatum oculatum*, *Falconeri*, *Devonianum*, *Dalhouseianum*, *crassinode*, *chrysotoxum*, *chrysanthum*, *bigibbum*, *superbum*, and many others. Mr. Burrows, the clever and genial gardener, escorted us through the Orchid and other houses, explaining all that was interesting and instructive, and the methods he had adopted to bring his Orchids to that state of perfection we found them in.

There are four very fine vineries, and the Vines were all one could desire at this period of the year. Everything in the kitchen garden was in excellent order and very clean. On the south wall an orchard-casing ran the whole length. We were told that no fruit of any importance has ever been grown. This could not have been the fault of the casing or its position; it would be impossible to have better. The fault must have been in the border and at the roots, and this is where Mr. Burrows has gone for his remedy. Excellent are the results. Good wood, plenty of bloom, and the prospects of a heavy fruit crop.

A stroll along shady walks, passing naturally formed gardens, rockeries, and by beautiful undulated lawns dotted with clumps and single specimens of flowering and foliage shrubs and Conifers, across terraces, here and there getting a view of the most beautiful mansion, brought us to the river bank of the Severn. Here one could stroll for miles, up hill and down, having all the while many interesting scenes to view.

It was pleasing to hear all the while how much interest Mr. and Mrs. Phillips took in horticulture and forestry, also in their workpeople. While I believe Mr. Burrows is the right man in the right place, I cannot but think how fortunate he is in having the honour of serving such employers. This was a pleasure trip, not taken with the view of writing a report of the place, otherwise several columns of interesting reading could have been penned.—G. A. BISHOP.

[We have received from Mr. G. Burrows a photograph of the Orchid house referred to by Mr. Bishop. This shows plants flowering splendidly and in the best of health, but the picture is unfortunately too dense for successful reproduction.]

THE QUALITY OF POTATOES.—Many years ago a Potato grower and buyer informed me that he had noticed that the kidney Potato grown in his parish turned black on those lands on which woollen refuse from the blanket manufactories was used as manure. Now, as wool decomposes into nitrogen, this corroborates "W. G.'s" opinion, that the discolouration is caused by the use of nitrate of soda. This did not occur in dry seasons, as the wool not undergoing decomposition would fail to supply nitrogen to the plants.—OXON.

ROSE SHOW FIXTURES FOR 1897.

- June 17th (Thursday).—Colchester and Ryde.
 „ 18th (Friday).—Portsmouth (N.R.S.).
 „ 26th (Saturday).—Windsor.
 „ 29th (Tuesday).—Canterbury, Sutton, and Westminster (R.H.S.).
 „ 30th (Wednesday).—Croydon.
 July 2nd (Friday).—Crystal Palace (N.R.S.).
 „ 7th (Wednesday).—Glasgow and Reigate.
 „ 8th (Thursday).—Bath, Gloucester, and Woodbridge.
 „ 15th (Thursday).—Norwich (N.R.S.) and Helensburgh.
 „ 22nd (Thursday).—Halifax and Trentham.
 „ 27th (Tuesday).—Tibshelf.

The above are the only dates definitely fixed that have as yet reached me. I shall be glad to insert in the next list, which will be issued about the middle of April, any further fixtures that may be sent me.—
 EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts*

ROSE NOTES.

THE interesting note upon budding Roses so early as February 16th, which "W. R. Raillem" records in your issue of April 1st, inspires a few notes upon seasonable work in the rosery. By the way, I may say that this early budding is by no means new to us in the south coast counties, and although I have not budded so early as February 16th it has frequently been done in March. Hedge Briars that have stood over from the previous summer have only to make a little growth at the points of their branches to admit of the bark lifting freely. It has been our practice to utilise such stocks for new Roses. The plants are pushed on under glass, and the resulting buds taken as soon as we can lift the bark of the Briars. This was begun in March during the present season, and many will be budded by the time these notes can appear.

Why should we not use the Hybrid Sweet Briars as stocks, seeing they are very vigorous, hardy, and more precocious than the normal type of Sweet Briar? At present (April 2nd), and for some fortnight past, it has been easy to lift the bark of these early Roses. But it may be asked, Where is the benefit of this early insertion of buds? In the case of new or very scarce varieties we can often secure a plant from a bud that would otherwise be lost so far as the increase of stock was concerned. My plan has been to cut back close as soon as the bud was firmly set, applying a little French or home-made grafting wax to the wound immediately. This conserves the whole of the sap for the benefit of the Rose bud, which soon pushes into growth, and is oftentimes little behind a maiden plant of the same variety that was budded the previous summer.

Taken all round our Roses are not at all forward for early April, and unless we get more sun and less cold winds I fear the earlier date found necessary for the Portsmouth gathering of the National Rose Society will prove too early to secure even our best garden and single Roses in their full beauty. We generally look to the early or Southern meeting of the N.R.S. to supply the finest of our so-called garden Roses. Why "garden Roses?" and why not "singles and semi-doubles?" They do not include such as Marie Van Houtte, Général Jacqueminot, Gloire de Dijon, and others, certainly much more deserving of the name Garden Roses than the majority of those now classed under that heading. But if we venture into the realms of classification we are in trouble immediately we step over the border line, and many rosarians, as well as the all-round florist, must be weary of the subject.

Pruning and spring mulching should be completed by now, and it is high time we cut back all budded stocks, whether dwarfs or standards, and also commence cutting away the numerous eyes certain to break from all young hedge Briars. Dwarf maidens need a careful examination at the same time. Our plan is to remove a little of the soil when budding dwarfs, and as the stocks are planted very shallow, a little soil being drawn up to them so that they have the appearance of Potatoes earthed up, there is little to remove before the bud can be placed well down upon the roots of the stock. This earthing keeps the bark soft and pliable, so that it is much easier to lift when inserting the bud. We prefer the bud to remain exposed all through the winter, having experienced better results than when covered up. This appears strange, because we find earthing up of dwarf plants a great, in fact a perfect safeguard against injury from frost to the lower eyes, and it would seem that the same rule should hold good with dormant buds upon dwarf stocks. But such has not been our experience, or that of our neighbours.

But I am wandering somewhat from seasonable work. I wished to point out the need of carefully looking over dwarfs for suckers, even to going over them three or four times before drawing any of the surrounding soil around the Rose bud once more. Choose a time when the ground works well, or go over the plants and place a little prepared

compost around the growing bud after it has made some 4 to 6 inches. The Rose growth is apt to swell very rapidly, and oftentimes overruns the stock in this direction. A dressing of soil not only aids the Rose and stock to unite better, but induces own shoots from the Rose.

Be careful to stake early, and also to secure the maiden growths upon standards. In the latter case it is undoubtedly best to have a stake that will support both Briar and Rose. Trade growers generally use split sticks of from 2 to 3 feet in length, according to the vigour of the variety. These are securely fastened to the Briar stem some foot or so below the maiden growth, and the latter tied to the stick projecting above. With the amateurs' few a stake is not so much an object from point of cost as with those growing several thousands, and I recommend this in preference. Some consideration should be given to the relative heights of varieties. To put the same stake to La France or Baroness Rothschild that would be suitable for Madame Gabriel Luizet or Margaret Dickson is absurd; while if they were reversed the support would be quite useless to the two last named varieties.

Insects will soon be prevalent. I noted many aphids in sheltered corners during the few sunny days of late March. Soon, too, we shall have the Rose maggot or grub, more than one species of caterpillar and other insect pests at our favourites. There is nothing more successful than hand-picking in this case, and the more prompt we are to do this the better it will be. It does not take long to look over a few Roses if one take it in hand before the enemy has become numerous, and three or four brief visits are more effectual besides being less labour in the end.

Under glass we are now in full beauty; even an unheated house is carrying a fine show of bloom. The chief points are to battle steadily and perseveringly against insects, and to be sure that only mild measures are used. These will be ample if one persevere, and more than ever so if early measures were taken. This is the secret of success in all plant culture. Of course it is easy to kill the insects at any time, but it is far from an easy task to do so when well established without great risk of serious injury to the plant as well.

All Roses in pots will enjoy a little liquid manure now, and climbers turned into borders or tubs should have a liberal supply. Ventilation is an important item at this season. Cold winds are so often accompanied by bright sun, the temperature rises rapidly, and yet we fear to ventilate on account of a slight draught of keen air. Afford a little ventilation early, instead of delaying until the sun has caused the temperature to rise too high. Of course everyone is aware that draughts are the chief source of mildew, and will be careful to apply all ventilation upon the sheltered side.

Even a slight shade is admirable should clear weather set in. This need only be very slight indeed, just enough to break the burning power of the sun, and yet not detract from its light and influence. In a house devoted to Roses a slight damping down of liquid manure is a great help to the foliage late in the afternoon and early in the morning.—
 PRACTICE.

EMIGRANTS' INFORMATION.—The April Circulars of the Emigrants' Information Office and the new annual editions of the Handbooks show the present prospects of emigration. This is the best season of the year for emigrants to go to Canada, but there is no demand for anyone except farmers with capital and experienced farm labourers. All emigrants are specially warned against paying premiums or other fees to any agency or person in this country for situations as farm pupils with farmers in Canada. They should in all cases apply to the Canadian Government Agents here or to this Office. In New South Wales the number of unemployed persons is now inconsiderable, and the prospects of the colony generally are improving. In Victoria the supply of labour in Melbourne, Warrnambool, Sale, and elsewhere is sufficient, except that there is an opening for good farm hands in parts. The drought has greatly affected the harvest, and it is estimated that the average yield of Wheat will be under 5 bushels an acre; better prices, however, will be received. In accordance with the recommendations of the Mildura Commission the Government has made an advance of money to the settlement on certain conditions. In South Australia, owing to the continuance of dry weather, farms, orchards, and fruit trees have suffered considerably, and the demand for labour is small, though there has been some demand for married couples without encumbrances for station, farm, and domestic service. Queensland has made fairly satisfactory progress during the last year, and the able-bodied population is generally well employed. There is a fair demand at Rockhampton for practical farm labourers and ploughmen. In Western Australia the population, though rapidly increasing, is still not more than 140,000, and therefore the demand for labour is necessarily limited. In New Zealand all kinds of employment at Auckland have been plentiful, and all the factories and mills are being worked full handed. In most other parts also of the colony, both in large towns and in country districts, employment has been good, as is usually the case during the summer season. Shearers, harvesters, and farm hands have been equally busy, but with the completion of shearing and harvesting the demand for these has declined. According to a large number of official reports from all parts of Cape Colony, dated the end of 1896, the cost of living has considerably increased owing to drought and the approach of rinderpest.—*Emigrants' Information Office, 31, Broadway, Westminster.*

THE CELERY FLY (TEPHRITIS ONOPORDINIS).

GREAT injury is frequently caused to Celery and Parsnips by the larvæ of the Celery fly. In mild seasons they are found, however late the Celery is dug up. In one bad attack, which occurred in 1895, larvæ were found in the leaves as late as the beginning of December. Parsnips are also attacked by this fly in some seasons, and the affected roots are small, much forked, and generally of a bad shape.

The larvæ make mines or passages in the leaves in their parenchyma, and feed upon the soft, juicy substance. The leaf soon contracts, whitish patches appear, in which larvæ can be found, and after a short period it shrivels up, and is utterly useless to the plant. In the case of Celery plants thus infested the stalks or stems, that have been earthed up in order that they may become blanched, cannot grow and fill out properly. Sometimes the plant is killed, or the Celery is small and green.

The larvæ not only make mines in the leaves, but they get down into the blanched Celery stems. They have been found there in company with the larvæ of the Celery stem fly, *Piophilæ api*, between the folds

FIG. 65.—1. Fly magnified. 2. Larva magnified. 3. Pupa, natural size. Lines showing natural size of Fly and Larva.

close to the somewhat bulb-like end, evidently feeding upon the sweet juice. Their passage down the stems can be distinctly traced by rusty marks, which materially injure the appearance and the flavour of the Celery, and in some cases cause it to rot.

LIFE HISTORY.

The fly (fig. 1) first appears in April; it is very small, only about one-eighth of an inch in length, with a wing expanse of nearly half an inch. It is tawny brown in colour, or, as Meigen terms it, "honey yellow," with the under part of the body light coloured. The wings are iridescent, with oblique lines of brownish or rusty spots running through them, and the poisers are dark yellow. The six legs are dark yellow and covered with black hairs. When the fly is at rest upon the plants its wings are folded in an upright direction.

The female fly, furnished with a long ovipositor, is larger than the male. It places its eggs singly upon the upper sides of the Celery and Parsnip plants. Many eggs are laid by one female. The eggs are hatched in about six days, and the larvæ from them at once bury themselves in the leaf tissues and form mines within them. They are very light green, without legs, and the dark line of the alimentary canal is visible along the back. The body is thick, pointed at the head and squared off at the tail end, upon which there are black tubercles. In about fourteen days the larva changes to a pupa, either remaining in the leaf or falling to the ground. From the pupa, which is oval, of a light yellow colour, barrel-shaped, much wrinkled, and about one-eighth of an inch long, the fly comes in a few days and establishes new generations. There are several broods or generations in the course of the summer, and the pupæ of the last generation remain in the earth and in pieces of leaf and stalk.

MODE OF PREVENTION AND REMEDIES.

As many of the pupæ remain in the earth it is most essential when the Celery crop has been taken from the trenches that the earth should be carefully levelled and well dug, and the upper surface buried deeply to prevent the flies from coming up. This should also be done in the case of infested Parsnips. A good dressing of finely powdered lime or gas lime might be applied with advantage.

Every particle of foliage and stem must be deeply buried, though it is far better that these should be collected and burnt directly the Celery or the Parsnips have been dug. All this should be burned, because if it is put in lumps or upon compost heaps or mixens not in active fermentation, it is most probable that pupæ will be carried out with manure for Celery or Parsnips or other crops grown near. This pest will not be stamped out unless Celery and Parsnip growers are most particular in destroying the remains of infested plants.

Thistles also should be kept down. Curtis says that the fly infests the "Cotton Thistle," *Onopordum acanthium*. Meigen and Macquart both say that it infests Thistles in France and Germany.

In the early days of this infestation it would be possible to check the attack considerably, at all events in gardens and allotment ground, by pinching the infested leaves, which may be detected at once by the peculiar marks upon them, so as to kill the larvæ within them. This would be difficult where Celery and Parsnips are grown upon a large scale. The plants should be examined when they are quite small, as the flies appear very early in favourable seasons. Pinching must be carefully done, so as to damage the leaves as little as possible, especially when they are small.

It is desirable to force rapid leaf growth where there is a bad attack. Nitrate of soda mixed with a little agricultural salt will effect this.

Finely powdered soot or lime scattered over the plants while the dew

is on them is likely to prevent the flies from laying eggs upon the leaves. A mixture of finely powdered soot and lime in the proportion of 1 bushel of lime to 3 bushels of soot has been found efficacious if put on when the leaves are damp from dew or rain.

Spraying the plants with various washes has proved to be beneficial. A mixture of paraffin and softsoap and water, at the rate of a quart of paraffin and half a pound of softsoap to 10 gallons of water, has been found very effective. The paraffin and softsoap must be thoroughly incorporated in a small quantity of hot water before being mixed with the cold water. A wash made with a pint of carbolic acid and half a pound of softsoap to 10 gallons of water has been tried also with advantage. These solutions should be sprayed lightly on the plants by means of a knapsack machine, and will prevent the flies from laying eggs upon them. It will be necessary to spray twice or more often during the season.—(Board of Agriculture Leaflet, No. 35)

PRESCOT HOUSE.

THE gardens at Prescott House are famous for the fine representative collection of hardy fruits, as well as high-class Grapes, Camellias, and Orchids. To use a garden phrase, other things are done well, but these are specially noteworthy. Prescott House, the home of W. Holcroft, Esq., which is one mile from Stourbridge, is a well appointed country residence, fitted up more for genuine domestic comfort and elegance than mere external appearances. The walls are mantled with a wealth of foliage, including a large specimen of *Magnolia grandiflora*, *Garrya elliptica*, *Crataegus pyracantha*, *Roses*, *Ampelopsis*, and *Clematis*. On a border near at hand there was a choice selection of Conifers, including *Thuia occidentalis ericoides*, *T. occidentalis Hoveyi*, *T. occidentalis pendula*, *T. Vernæueana*, *T. Wareana*, *Thniopsis borealis*, *T. dolobrata variegata*, and *Eurya latifolia variegata* with its beautiful golden foliage.

Of finer and larger specimens of Conifers in different parts of the grounds we noticed *Abies Remonti*, *Cupressus macrocarpa*, *C. Lawsoniana argentea*, *C. Lawsoniana erecta viridis*, *C. Lawsoniana alba variegata*, *Juniperus chinensis*, *J. chinensis aurea*, *J. virginiana glauca*, *Prumnopitys elegans*, *Retinospora pisifera*, *R. plumosa*, *R. plumosa aurea*, *Taxus baccata*, and *T. baccata aurea variegata*. Skirting the pleasure ground there was a neat flower garden, the beds laid out in geometric fashion, the edgings and divisional lines being formed of *Sedums*, *Antennaria*, and *Saxifraga*, all indicating how exquisitely beautiful it would be when arranged in its bright summer attire, though one of the wildest days we had in March was not the time to see it to advantage. In close proximity was the hardy fernery, where many choice Ferns found a congenial home. In one corner of the fernery there was a large *Aralia Sieboldi*, which had occupied the same position for twenty years, a sufficient proof of its hardihood.

We now enter the walled-in fruit garden, and here, although as we have stated above, it was a cold wintry March day, had time permitted we could have lingered long over the fruit trees. These are to be seen under every form and feature of training. The wall trees were perfect specimens of the pruner's and trainer's art, as were the espaliers around the garden walks. There were also numerous bushes and pyramids, 8 or 9 feet high, all smothered with myriads of blossom buds. Upright cordons were in good evidence, and filled up many a nook and corner that would otherwise have been vacant. The walls on three sides of the garden were furnished with handsomely trained trees, while on the south side were the vineries and other glass houses. Amongst the Pears on the walls there were *Beurré Superfin*, *Glou Morceau*, *Beurré Rance*, *Beurré Bachelier*, *Jargonelle* (smothered with fruit buds), *Swan's Egg*, *Winter Nelis*, and *Beurré Clairgeau*; this latter Pear, though generally not considered more than second or third rate, comes good at Prescott, and a small tree, covering 42 square feet of wall, produced 42 lbs. of fruit, fine Pears weighing 5 lbs. 12 ozs.

As espaliers there were *Maréchal de Cour*, *Madame Treyve*, *Doyenné d'Été*, *General Todleben* (a good November Pear), *Fondante d'Antonne*, *Flemish Beauty*, *Zephirin Grégoire*, *Beurré d'Amanlis*, *Catillac*, *Passe Crassane*, *Bon Chrétien*, *Autumn Bergamotte*, *Knight's Monarch*, *Thompson's*, *Darondeau*, *Nouvelle Fulvie* (a late delicious Pear, in use during January and February), and *Olivier de Serres*, which was in fine condition up to the time of our visit. A good late Pear is a desideratum, to come into use when the bulk of the autumn Pears are over. *Passe Crassane*, *Nouvelle Fulvie*, and *Olivier de Serres* are amongst the best to fill up this gap, and to give a supply of fruit during January, February, and into March.

Then as pyramids there were good specimens of *Beurré d'Anjou*, *Huyshe's Prince of Wales*, *Albertine*, *Marie Louise*, *Louise Bonne de Jersey*, *Swan's Egg*, *Beurré Giffard*, *Souvenir de Congrès*, *Beurré Diel*, and *Winter Nelis*. The cordons included *Duchesse d'Angoulême*, *Pitmaston Duchess*, *Seckle*, and *Easter Beurré*. Of Plums on the walls there were *Bryanston Gage*, *Orleans*, *Green Gage*, *Coe's Golden Drop*, *White Magnnm Bonum*, *Prince Engleheart*, *Cox's Emperor*, *Pond's Seedling*, *The Czar*, *Victoria*, and *Goliath*. On the various squares we noticed good breadths of *Strawberries*, *Raspberries*, and other small fruits, all in good condition, and promising an abundance of fruit.

Turning into the vineries, the early house was started and beginning to show its fruit. The Vines in the late house were just swelling their buds. In each house there was the usual run of sorts, and to all appearance, when the fruiting time comes round, will be able to give a good account of themselves. The back wall of each house was draped with fine *Camellias*, reaching to the top of the house, and all in most

luxuriant health. The varieties cultivated were imbricata, anemonæ-flora, alba pleno, Mathotiana, Beali, Countess of Derby, fimbriata alba, Parini, Fordi, and Victoria antwerpensis.

Two small houses devoted chiefly to Orchids contained some good examples of the popular varieties of Cattleyas, Cypripediums, Dendrobiums, Vandas, Lælias, Angræcums, Aërides, Phalænopsis, and many others. The Orchids looked well cared for, and bore unmistakeable traces of skilful cultivation.

In an adjoining greenhouse were good Cinerarias, and other useful plants for house embellishment, and in the Peach house were nicely trained trees of Alexander, Early Beatrice, Early Louise, Royal George, Bellegarde, Grosse Mignonne, and Pitmaston Orange Nectarine. On a shelf close to the glass was the collection of Chrysanthemums in small pots, in which were all the leading sorts, new and old. Whilst Mr. Stephens studies the wants of the Chrysanthemum, and grows his plants and flowers to a state of high perfection, it is not to the detriment of other things, for every plant, whether it be inside or out, is equally cared for and grown to the best advantage.

In the kitchen garden proper there were useful frames for forcing and plant culture, the usual flats of vegetables, and in the orchard a collection of the leading sorts of Apples, including between thirty and forty of the best and newest sorts in cultivation. It would only be a repetition of what is continually appearing in lists of the best Apples to enumerate the sorts; this may, however, be said, the trees were healthy and vigorous, and such as any gardener and his employer might be equally proud of. In conclusion, the gardens were in the best state of keeping, and reflected the highest credit on the skill and care of Mr. Stephens, and were fit for any gentleman to visit.—QUINTIN READ, *Evesham*.

UTRICULARIA RHYTROPHYLLA.

WHEN well grown some of the most notable of the Bladderworts are exceedingly pretty, and should be more frequently seen in cultivation. One of the best of these is that depicted in the illustration (fig. 66), viz., *Utricularia rhytrophylla*. The specific name is apparently derived from a Greek word referring to the long, narrow, strap-like leaves, but the chief character of the plant rests in the flowers. These are large, of a fine purplish hue, with an orange-coloured projection at the base of the broad rounded lip-like portion, and are borne in slender graceful racemes from the base of the plant. It thrives well in small baskets of peat and sphagnum suspended from the roof of an intermediate house.

IN METROPOLITAN NURSERIES.

AMARYLLIS AT CHELSEA.

AMARYLLIS or Hippeastrums, it matters not which you call them, for by either name they are greenhouse bulbous plants that produce richly beautiful displays of flowers at this period of the year. To the botanist they are Hippeastrums, but with the gardener the older name still holds good, and finds most favour. As it is to the latter that the *Journal of Horticulture* speaks more particularly, their cognomen shall stand at the head of these brief notes, written to call particular attention to one of the finest collections of Amaryllis in the country—that of Messrs. J. Veitch & Sons, Ltd., Royal Exotic Nursery, Chelsea. Here may be seen plant after plant, flower after flower, all in the full glow of health, notwithstanding adverse atmospheric conditions; indeed in such state as to prove their adaptability for town culture, while at the same time pointing conclusively to the careful attention that is bestowed upon them by Mr. John Heal, the grower. These plants have many desirable attributes, a fact which would warrant their being far higher in favour than is the case at the present moment.

The Chelsea plants represent practically all stages from the juvenile that has not yet flowered to the oldster that is relatively speaking getting hoary with honourable age. Then there are others that are passing or past their prime of flowering for this season, while many more are just pushing up the stout stems at the apex of which will be the handsome blooms. The extension or elongation of the flowering season is simply a question of culture with which every practical cultivator is familiar, and it is worthy of adoption by reason of the beautiful spectacle that can be produced even where only a dozen specimens are at the summit of their beauty at the same time. Successional drying off and successional starting are the backbone of the system referred to.

Amongst the hundreds of plants to be seen, including some of the best varieties in cultivation, and representing years of patient labour in hybridisation, the colours most noticeable are shades of red, though persistent efforts are still being made to widen the range. In this direction there is one break that must be reckoned with in the future, for it provides that encouragement which is dear to the heart of all. It is found in a new one named Arona, in the colour of which yellow may be distinctly seen, though it is not yet such as would justify an appellation as Golden Queen. It is a step onward, as everyone will admit. The ground colour is pale green perceptibly flushed yellow, and with orange red markings at the edges of the bloom, which is, in comparison with some of the others, a trifle faulty in form. However, the shape can readily be had; it is the colour that is the difficulty over which the experimentalist has to rise, and it is to be hoped will rise.

The variety just alluded to is the most distinct break in the collection, but some of the others, both new and old, are of the very best quality, both in respect of colour and of form. Some are intensely rich in the depth of colour, while others are of exquisite softness. Mention may be made of a few of these, commencing with Surprise. This is a splendid variety, of which the ground colour is white, and the veins bright red. The form and substance leave little to be desired. Richly beautiful are the very deep red flowers of Ora, while those of Tamora—velvety crimson, suffused with lake—are no less attractive. Very charming is Florizee, with its bright red streaks on the white ground; and the same may well be said of Mephista, which, though small, is of great merit; the colour is salmon rose.

Of the most intense shade of velvety crimson is Euphrasia, but it is

FIG. 66.—UTRICULARIA RHYTROPHYLLA.

not more conspicuous than Scio, with its bright, shapely, crimson scarlet blooms. Others of more than ordinary merit are Hidalgo, Cythera, Camis, Atalante, Nysa, Francisca, and Emin. These are only a few of the comparatively new ones, but they are all to which reference can now be made.—D. R.

CLIVIAS AT FOREST HILL.

It cannot yet be said of Clivias that they have become really popular plants, but it is certain that their culture is becoming more and more extended, probably by reason of the many improved varieties that are being yearly introduced by hybridists of note. It is, too, equally a fact that they are deserving of far more extended attention both by professional and amateur cultivators, for they are amongst the very easiest of plants to grow, and moreover the price asked for them is by no means exorbitant, though some of the new and scarce are perhaps beyond the very small amateur. A large portion of the credit of popularising the tuberous-rooted Begonia is universally and deservedly accorded to the veteran hybridist Mr. John Laing, and if the Clivia ever command even a moiety of the esteem claimed by the more gorgeous plant just mentioned the same gentleman will find his renown still more enhanced.

The firm of Messrs. J. Laing & Sons has long been striving to widen the favour now given to the *Clivia*, and it is to be hoped that its efforts will be crowned by success.

If anyone desire a good object lesson in the effect that may be produced by a collection of *Clivias*, let him hasten to make a pilgrimage to the Stanstead Park Nurseries, when a very fine display will be the certain reward. There may be found a large span-roofed structure almost wholly devoted to them, comprising plants of all sizes, from those that are now blooming for the first time to others that are giants in comparison, and have seen many years of growth. The veterans are mainly upon the central staging of the house, with the juveniles arrayed along the two side and end stages. The broad, leathery, clean, strap-like leaves of dark glossy green hue set off the flowers, which, as everyone knows, are produced in circular heads of considerable size on a stout footstalk, to the best advantage, and force one to wonder why they are not more grown.

For the conservatory, the greenhouse, or the window *Clivias* are admirably adapted, they not requiring either very much heat or attention, the most important points in the latter direction being good judgment in watering and perfect cleanliness. They cannot be said to be plants highly susceptible to visitations from insects, for they are not; but it is nevertheless a fact that if the leaves are frequently sponged enemies are prevented obtaining a hold, the pores of the leaves are kept constantly open, and the plants thrive far better accordingly, for to all plants, the same as to ourselves, the maintenance of perfect cleanliness is one of the royal roads to health.

Besides bearing in mind the easiness of culture the intending grower should make a memorandum of the fact that *Clivias* last for a very considerable time in flower—several weeks in fact. This alone should prove a distinct recommendation in their favour. Then the grower who thirsts for fame can amuse himself by seeking new varieties by the aid of cross fertilisation. There is abundance of room still left for the extension of the range of colouration, and constant experiments carried out on rational lines are practically sure to eventuate in something distinct and good. So far the colours are mainly shades of orange, though some are almost scarlet, so that a pure white or a yellow would be hailed with delight, though it is probable, judging by the progress that has been made so far, it will be some time ere either of these is given to us.

To name and describe all the varieties would be impossible, so the selection shall be limited to one dozen, each of which will, of course, be good. *Duchess of York*, reddish salmon, with a lemon yellow throat, is worth watching, as is the shapely *Orange Gem*. *Firefly* is large and rich in colour, while *sanguinea*, of which the colour is described by the varietal name, is very fine. Then there are *Comet*, *Mrs. John Laing*, *Mrs. Davidson*, *Princess May*, *Vesuvius*, *Princess of Wales*, *Sunrise*, and *Fascination*, all decidedly above the average in size, colour, and shape, and worthy of being grown everywhere.—VISITOR.

DAFFODILS AT DITTON.

PERHAPS no one has done more to popularise the Daffodil than Mr. Peter Barr, whose name in connection with the flower is a household word. Many years have now elapsed since he turned his attention in the direction of the Daffodil, and by dint of the perseverance characteristic of a Scotsman he is in possession of a collection, the magnitude and variety of which are unsurpassed. Aided by sons imbued with a kindred spirit the gigantic work is still going on, and year by year fresh novelties are put in the market, which trace their origin to the famous nurseries at Ditton. To say there are acres of these charming flowers is no exaggeration, and at the present time they form a picture worth going a long way to see. Here is a large area of *Narcissus Barri* conspicuous, the king of the Barri section. Thousands of graceful flowers sway hither and thither in the breeze, or make themselves more showy in the sunlight. Near at hand is a similar quarter of *Emperor*. What a contrast is formed by its trumpet form and bold sturdy habit! It seems to be the type of true manliness in a Daffodil, while the former has more of the fragility of the female sex. To fully appreciate a visit to the Ditton Nurseries one ought to be an enthusiast versed in every new departure in the world of Daffodils, otherwise the variety is enough to confuse.

To speak of and describe only a small portion of Messrs. Barr's Daffodils would be a task too great in limited space, but one thing that strikes the visitor is the method and orderliness that prevail. Every variety has its own bed, either small or large, as the case may be, and one looks in vain for a flower of one sort in the portion allotted to another. There is no confusion of names, and when one comes to think of the continual lifting, drying, and transplanting that is ever going on, one has some idea of the amount of labour required, and also of the excellence of the system by which it is done. Each season a little more space is taken up, and in addition to the large extent of waving flowers and foliage there are other portions on which the younger bulbs are grown through their various stages till they are ready for sale. Fertilisers are sparingly used, the principal being broken bones, which are excellent for retaining moisture. Messrs. Barr & Sons do nothing by halves, and have made themselves thoroughly acquainted with the habits and requirements of the flower that has made the firm famous.

Turning again to the varieties, there are contrasts enough even in the various sections to suit the tastes of all. In the trumpet family comes the elegant little *Cyclamineus* major, a charming flower, yet so modest that one might be excused for passing it by. It is valuable for pot culture, though its true home seems to be in some shady nook in the

rock garden. How different is *Glory of Leyden*, with its bold yellow trumpet and perianth! Yet of its type how beautiful! Amongst others that one could hardly pass without stopping to take a second look is *N. Johnstoni* Queen of Spain. For pot culture the variety is unsurpassed, and its free-blooming qualities render it invaluable for bedding. Its blooms are of a delicate clear yellow, and of its kind there is perhaps none better in cultivation. One might go on to any length telling of the beauties of *P. R. Barr*, *Sharman Crawford*, *Emperor*, *Monarch*, *J. B. M. Camm*, sometimes called the Queen of the trumpets, and many another. *Weardale Perfection* is truly a glorious flower with its spotless perianth and bold trumpet. *Madame de Graaf* is one of the finest of the white trumpets, and *William Goldring* has all the characteristics of a true Swan's-neck Daffodil.

Beauty occupies a high position in the incomparabilis section, and is a bold handsome flower. *Frank Miles* is an elegant flower with yellow perianth and cup. It is very suitable for planting in grass. So striking are the blooms of *Gloria Mundi*, with its rich yellow perianth and large cup, that one cannot fail to notice it; and *Lulworth* by some is considered equally fine. Though better known and more widely spread *Sir Watkin* holds its own as one of the most beautiful and accommodating of the section. Of the Barri family, *N. Barri* conspicuus truly justifies its name, and as proof of its popularity we learnt that though very largely grown at Ditton the end of each season finds the stock sold out. *Flora Wilson* is a charming flower with white perianth and cup, edged with orange scarlet. *Siddington* is a recent novelty, with yellow petals and a large open cup, besides which it is very floriferous.

The Leeds section, popular for beauty and fragrance, contains numerous gems. There is *Duchess of Westminster*, one of the many recipients of a first-class certificate, very distinct and handsomely striking; *Katherine Spurrell*, broad and substantial, with canary yellow cup; and *Minnie Hume*, with its large white perianth and cup, passing from canary to white. *N. Nelsoni* major is one of the most striking of Nelson's Daffodils, though there is much to admire in *aurantius* and *Mrs. C. J. Backhouse*. In the Burbidgei section one is struck with the elegance of *Ellen Barr*, a most refined flower with snow white perianth. *Falstaff* is also a telling flower; and *Mrs. C. Bowley*, a novelty of last year, has characteristics that render it equally striking. *John Bain* is a useful variety, and admirable for planting in grass, and though these are but a few of the forms of the lovely *Poet's Daffodil*, the remainder of the section is equally charming.

These scanty recollections give but a brief outline of what the firm has done to popularise the flower. The work is going on with increasing vigour. Each season sees the list of varieties longer and the area of Daffodils broader. With the growing popularity of the flower what a future there seems to lie before the Long Ditton Nurseries and the firm that controls them!—MONOCLE.

THE YOUNG GARDENERS' DOMAIN.

RASPBERRY CULTURE.

I WAS recently surprised while looking through some gardens in this district (Manchester) to see so many Raspberries trained in the birch-broom style—that is, bundling them round a pole and tying in that position with a cord. A better plan is the following, as proved by long practice. The rows should be from 4 to 6 feet apart according to the kind grown. Then have ready some stout poles about 7 feet long—young Larches out of a thinned plantation are the best, as they are neat and keep in good condition a long time. Failing these common deal posts 3 inches square will answer the purpose. These are placed firmly about every 7 yards in the rows, stretching two wires from end to end, one 3 and the other 5 feet from the ground. To these wires tie the canes 8 inches apart. Then give a surface mulching of half-decayed manure 18 inches each side of the rows. Fork down the centre lightly, then all will be neat. When the new canes appear remove the weaker, leaving just as many as will cover the wires the following year, and as soon as the fruit is gathered cut out the old canes to make room for the young ones so as to get well ripened. I think if growers generally were to adopt this simple method they would have more and finer fruit.—J. C., Lancashire.

THE GLOXINIA.

THE original species of *Gloxinia* was imported from South America about 1815. It derives its name from P. B. Gloxin, a botanist of Colmar, and the flowers were deflexed or drooping. The erect-flowered section originated in a garden sport, but where and with whom this new departure occurred there are no data to show.

For late plants seeds may still be sown, using a very fine mixture of leaf soil, loam, and sand. Immerse the pot in a tank of tepid water before sowing. Sow thinly. Cover the pot with glass, and keep dark. When the seedlings appear remove the covering, and admit all the light possible, but shade from direct sun.

As soon as the seedlings are large enough to handle place them singly into small 60's, using similar compost as before, but do not press the soil firmly, a gentle rap of the pots on the bench being sufficient. When freely rooted shift the plants into their flowering pots, 5-inch. The compost this time should be leaf soil two parts, loam one part, sand one part, and a slight sprinkling of soot. Never allow the plants to get dry, and keep the syringe playing amongst the pots. If all last season's bulbs are not potted, I advise that all the old soil be not shaken off, for the following reason:—The last *Gloxinias* I had to do with, I found

when turning them out of the old pots had young roots all round the old ball of soil; the corms had made a top growth of half an inch, so I carefully pricked off enough soil to allow of repotting in the same size pots as before. I used similar compost to that given for the final potting of seedlings, and gave the plants the same kind of treatment. The temperature ranged from 60° at night to 75° in the daytime. The plants produced splendid foliage, and twelve to eighteen flowers each. The gentleman and gardener gave me great praise, and said I had hit the right treatment.—YORKSHIREMAN.

FORCING FRENCH BEANS.

FRENCH Beans for forcing may be sown either in pots or in boxes. I think the best plan is to sow seven or eight beans in a 60-pot, as when sown in boxes for transplanting the roots are liable to be injured, and the growth consequently checked. Seeds germinate well when the pots are placed on the pipes at the back of a Cucumber house, and the soil kept moist. In about a week the plants will be ready for potting. The best time for this is when the first two leaves are fully developed.

They should be carefully turned out of the 60's and potted in 16's, using one crock and a handful of horse droppings for drainage. Care must be taken not to break the ball of soil or bruise the roots. Sutton's Forcing Dwarf Bean is very good. They grow well potted in a compost of two parts loam to one each of good horse droppings, and one part leaf soil. They require a temperature from 60° to 70°, placing them as near the glass as possible. Care should be taken not to let them suffer by want of water. A good syringing once or twice a day also greatly helps them, and keeps down red spider. When the plants begin to flower they must be kept rather drier till the pods form, when liberal supplies of water are necessary, and liquid manure two or three times a week is beneficial.—W. W.

THE BANANA.

THE Banana or Musa can be grown in any ordinary stove temperature, provided there is abundance of moisture during the growing period. Select strong suckers, and pot in a compost of three parts loam with one of leaf soil and horse droppings, at the same time making it firm, as the Banana is a very strong growing plant. Having filled these pots with roots, plant out in a bed if convenient; it is far better than growing in pots or tubs. Pay particular attention to the watering, as the plants take a large amount when thoroughly established. If planted, say in September, and kept gradually on the move they will be strong, healthy plants by April, when they will commence to show signs of flowering; then keep the atmosphere of the house drier till this stage is over, together with a free circulation of air, to insure fertilisation. Give liquid manure in a weak state, when required, for a week or two; it may then be increased in strength as occasion demands till the fruit shows signs of colouring, when it must be given very sparingly. A good plan is to cut the fruit with a part of the stem attached and hang it on wires close to the glass to receive all the sun possible.

There are several varieties of Musas, but M. Cavendishi is one of the best, I think; it does not take up so much room as the majority of others. The fruit not only ripens in the way suggested, but gives more time for the growing of a young plant after the old one has been early removed.—C. E. L.

CALANTHES.

CALANTHE VEITCHI and C. vestita are amongst the most beautiful and useful winter decorative Orchids we have, and are easily grown under ordinary conditions. Given plenty of heat and moisture in the growing season, with care in preparing the soil, they may be had in great beauty during two of the dullest months, December and January. As the flower spikes are cut remove the plants into a cool house, keeping them perfectly dry and out of the reach of frost until the beginning of April.

Some growers advocate the pseudo-bulbs being shaken out of the pots and laid in boxes of moss until they start, but owing to the chance of decay it is safer to let them remain in the pots until they begin to show signs of growth; they must then be very carefully shaken out. Discard all the old bulbs, and lay the new in a box or tray, removing part of the old roots. Why I say part is because some growers remove all the old roots, and then have trouble in keeping the bulbs upright when potting, whereas by leaving a couple of inches you have something to help to hold them in position until the new roots form.

Have the pots well cleaned, 32's being a suitable size, and nicely crocked. The soil should be composed of two parts good fibrous loam, with the fine knocked out, one part of cow manure, dry enough to pass through a quarter-inch riddle, one part of broken charcoal and crocks, with a little fertilising moss if available. If good fibrous loam cannot be obtained mix a little peat with the soil. Mix well and warm the compost. Fill the pots nearly to the rim, place from three to five pseudo-bulbs, according to size, in the centre of the pots, and let the growth lean outward as much as possible. Work the compost well around them among the old roots until the bulbs will stand, but do not bury them deeply. Place the pots on a shelf at the back of Cucumber or Melon house. Do not give water unless the weather be very hot, then choose a fine day, and sprinkle them with a fine rose. They will soon produce roots, and after the pots are well filled give liberal supplies of weak cow manure water right up to the time the flowers begin to open.

Calanthes are often spoilt by withholding the water too soon, and then, instead of producing long, well flowered spikes, they are often poor, and die away before half the flowers are open.—J. B., Eastnor Gardens.

CANNAS.

THESE beautiful plants are now starting into a new form of life after about three months' rest. They should be potted for the greenhouse and flower garden. We find the best compost to grow them in is three parts loam, two parts leaf mould, and one part sand. After potting they are placed in gentle heat until growth commences—a Peach house or vinery will be found a very suitable place for them. It will be necessary to fumigate them occasionally, as they are subject to attacks of green fly. During the growing season the plants require copious supplies of moisture, both at the roots and also overhead with the syringe. They may be planted out about the first week in June in a rich compost, attention being given to watering, which will be well repaid with a profusion of flowers. On the advent of frost they must be taken up, potted or boxed to preserve the roots from shrivelling, and kept in a cool dry place for the winter.—C. M.

CHIMONANTHUS FRAGRANS GRANDIFLORUS.

I THINK this fragrant winter-flowering shrub is not so well known as it deserves to be. Flowering as it does from December till late spring it comes in very useful for house and table decoration, sprays, and buttonholes. The flowers are a whitish yellow with dark centre, and are very sweet, especially C. fragrans, but C. f. grandiflorus is the better of the two, the flowers being larger and not so strongly scented.

The best situation for a plant is a south wall where it is fully exposed to the sun. Although quite hardy, whilst flowering a little protection should be given, such as mats suspended from the top of the wall, so that they may be drawn aside or rolled up during mild weather. They can also be used to protect the flowers during hot sun.

After flowering the shoots should be shortened to two or three buds, as the flowers are produced on the preceding season's growth. Overcrowding should be avoided, for unless the wood is well ripened flowers will not follow. The plants require deep rich sandy soil, and are usually propagated by layering in the autumn.—A. C. W., Belcarres.

MIGNONETTE.

MIGNONETTE is particularly welcome in winter and spring both in pots for conservatory and room decoration, and also for cutting. The seeds should be sown during the month of August. As the seedlings will not readily transplant we sow in the pots the plants are to flower in, these are 32's, or 6-inch, eight seeds being sown in each pot, covering lightly, and subsequently thinning the plants to five of the stronger. The compost consists of two parts good loam, one part leaf soil or well decayed manure, and enough sand to keep the whole porous. To every bushel of the mixture we add a shovelful of crushed mortar rubbish and a 48-potful of soot.

When the seed is sown the pots are placed in a frame to be protected from rain. When the plants appear they are afforded abundance of light and air to keep them sturdy, which is very important. Towards the end of September they are placed close to the glass in a pit or house, where a temperature of about 45° can be maintained; and air is admitted on all favourable occasions, for Mignonette must not be coddled. When the flower spikes appear weak liquid manure is given, also a sprinkling of artificial manure. To support the plants three or four light sticks are placed round the edge of the pot, and a piece of raffia twisted round them.—WORPLESDON.

EARLY FLOWERING CHRYSANTHEMUMS.

To obtain first-class blooms for exhibition of Madame C. Desgrange and its sports, G. Wermig and Mrs. Hawkins, healthy cuttings should be inserted during the last week of December singly in well-drained thumb pots, using a compost of equal parts loam, leaf mould, and silver sand. Plunge in cold frames free from frost, and as soon as rooted afford air on all favourable occasions, but avoid cold cutting winds. The plants will be ready for 60's by the middle of February, adding a sprinkling of wood ashes to the above compost. Return to the cold frame, and keep them close for a few days afterwards, admitting air gradually at first, then fully. Watering should be carefully attended to, never allowing the roots to become dry, or the plants will lose their lower leaves. Their next shift will be into 48's, using an extra part of loam. Never allow them to become root-bound, but examine and repot as they may require firmly from first to last to insure short-jointed wood. Still keep them in the cold frames, but draw the lights off during mild weather.

They will be ready for their final pots by the middle of May, 24's being a suitable size to flower the plants in. The compost that suits them well is found in three parts rough turfy loam, one each of leaf mould, sand and wood ashes, with a sprinkling of soot and bone dust. Before potting see that the soil is moist, as the plants ought not to require water for a couple of days, but use the syringe freely amongst them on all favourable occasions, then give a thorough watering to moisten the soil through to the drainage.

Stand the plants in their summer quarters in rows running north and south, and examine them two or three times a day for the purpose of watering. When the pots are filled with roots liquid manure should be afforded. A bag of soot placed in a tub of water with sheep droppings forms a good solution. Some of the plants will make their first break by the middle of June; remove the point with the bud, as that will cause them to grow more before showing the next crown bud; select three shoots, removing all others as fast as they appear; by the middle of July they will show the proper bud to select. From six to seven weeks elapse before the buds "take" and the blooms are fully

developed. A sprinkling of some approved fertiliser may be given as soon as the bud is set. House the plants as soon as they show colour, and slightly shade them.

Earwigs and green caterpillars are the two most troublesome pests, and hand-picking is the safest mode of riddance. If the above details of culture be carried out the plants will require no staking, and blooms that will not disgrace the exhibition table will be the result.—GROWER.

A FEW NOTES ON THE PINE APPLE.

WHEN the suckers are taken off in September they must be potted very firmly, and plunged in a hotbed as close to the glass as possible in a properly heated pit. They should be rooted in about six weeks, and will require little attention during the next two months. Keep them rather dry than wet. A great mistake at all times is the over-watering of Pines. Early in February the plants will be ready for the fruiting pots or planting out, the latter method saving much labour during the fruiting season.

For planting make up a good bed of leaves (as is usual when the plants are grown in pots and plunged), prepare a compost of three parts good turfy loam, one part horse droppings and leaf soil; a sprinkling of bone meal, horn shavings, Thomson's manure, wood ashes, and soot improving the mixture. Make the beds for planting 2 feet wide and 15 inches deep. The back one may be 12 or 15 inches higher than the next, by driving stakes into the bed and putting boards behind them. When planted turves should be laid between the plants, so that each one receives the full allowance of water when required.

The house must be kept at a temperature of 60° to 65° at night, allowing it to rise to 70° or 75° in the daytime for the first few weeks, then another rise of 5° may be given when the season has advanced a little more. Close early, and allow the temperature to rise to 100° with plenty of moisture. Water should be given very sparingly at the roots during the first year. In September the plants will be strong, and the temperature may be gradually lowered before the winter comes on, to 60° at night. They will not require any water from that time till starting again in February.

They should then begin to show signs of throwing up the fruits. A thorough watering ought then to be given, using it (and on all occasions) at a temperature of 85°. Raise the temperature to 70° at night, with a bottom heat of not less than 75°. Syringe on bright days, closing early with as much sun heat as possible. When flowering commences syringing must be done very lightly, not allowing any water to reach the flowers, or some of the pips will come deformed through defective fertilisation.

After the flowering afford the plants abundance of heat and moisture, but do not syringe them at this stage, or the water will lodge in the axils of the leaves of the crowns and make them grow out of proportion to the fruit. Keep liquid manure in the evaporating troughs. The fruits after a time will require staking, and great care must be taken to keep them straight, as they look very much better so both for table and exhibition than when the reverse. Watering must be attended to as required, giving the plants some stimulant, but when the fruit shows signs of colouring moisture must be withheld, or there will be a tendency to blackness of the pips, which should be bright and clear.

Though Pines are not generally grown, I hope these notes, the result of experience, may be useful to some readers of the "Domain."—C. E. L.

["J. L. G." sends a very creditable article as a "first try" on "Early Fruit Houses," but has prohibited its publication by omitting his name and address and writing on both sides of the paper. All young gardeners who desire to write acceptably for the press should read and preserve the *Journal of Horticulture* for December 31st, 1896, and those who do not possess it will find 3½d. sent in stamps to the publisher, with a request for a copy, a profitable investment. If "J. L. G." send his name and address his M.S. shall be returned to him for rectification.]

HARDY FRUIT GARDEN.

Planting Outdoor Figs.—Figs do not succeed in soil of a deep, strong texture, because they are likely in such to root deeply and grow too strongly, the wood resulting being sappy in character. They delight in a chalk subsoil, inasmuch as the soil overlying such must be naturally well drained, and is usually a fertile loam of calcareous nature. It should be made firm previous to planting, consolidating it only, however, when moderately dry. It is essential that a warm position be selected for the trees; one having a south or south-west aspect is the best. Position aids materially in modifying growth, assisting it to be short-jointed and ultimately fruitful. Unsuitable soils may be improved by artificial draining and adding lime rubbish or chalk to the staple material for planting in. Under these conditions the aspect is even of greater importance, for without abundance of sun the ripening of the shoots cannot

be fully effected. In no case add manure when preparing ground for Figs. Success will probably be better insured in soil below the average in fertility than in one possessing an excess of organic matter. The best time to plant is during the present month, choosing maiden trees.

Pruning Young Trees.—Young maiden trees being only furnished with one stem require cutting well back after planting, usually to a length of 15 inches. Two breaks equal in strength may be taken one from each side, which will form the first foundation. From these other shoots may be allowed to grow at regular distances in suitable positions for extension, leaving ample space between them for laying in fruiting shoots.

Pruning Old Trees.—The principal pruning necessary consists in thinning out and pruning back to a few buds a certain proportion of shoots. Shoots capable of bearing a crop must be retained at full length. Allow such as these ample space by clearing out crowded growths surrounding them. Shoots with wood buds only should be selected for close shortening in, thus affording an opportunity of furnishing the lower parts of branches with wood. The adoption of these principles of pruning annually insures the trees being kept in a vigorous and fruitful condition, as well as securing a well balanced growth over the entire space available.

Top-dressing Fruit Trees.—Newly formed plantations of fruit will be benefited considerably throughout the season by lightly mulching over the roots before the surface dries too much with manure in a half decayed lumpy state, this serving to preserve moisture in the soil, while admitting air and warmth. These conditions are essential to free growth, hence rich dressings of manure would not be so serviceable. Should the summer prove very dry the mulching may be renewed when necessary.

Mulching Old Trees.—Trees in bearing and having roots near the surface may have richer applications to the roots. A dressing of some approved artificial manure may be given to those trees where a good crop is anticipated or more growth is desirable. The most stimulating and easily dissolved fertilisers ought not to be wholly used at this period without admixture. Nitrate of soda is very quick in action. Sulphate of ammonia is also soluble, but not so rapid as the former. Soil retains ammonia some time while it remains as such, but under certain conditions it is quickly changed to nitrate, and if the roots do not then make use of it, it is washed through the soil. A good mixture of chemical manures consists of mineral superphosphate two parts, nitrate of soda one part, muriate of potash two parts, and dissolved bone one part. The whole should be well mixed, crushing as fine as possible. Apply 4 ozs. to the square yard, preferably mixing with soil or decayed manure for trees or bushes having abundance of roots near the surface, so that the fibres may not be injured. With deep-rooted trees the manure may be applied direct on the surface. Further dressings can be given when fruit is set, and again when swelling freely. Half the quantity applied at the first dressing is sufficient for successional applications.

Hoeing Fruit Borders.—Vacant soil between either young or old trees should be loosened with the hoe. This will act effectively in destroying germinating seedling weeds and improve the appearance of the quarters. In the case of young plantations a loose surface between the trees promotes the active growth desirable, inasmuch as air and warmth are admitted, moisture being conserved.

FRUIT FORCING.

Peaches and Nectarines.—*Earliest House.*—The very early varieties Alexander and Waterloo Peaches, with Cardinal Nectarine, have completed the stoning process, and are closely followed in this respect by Early Louise Peaches and Early Rivers Nectarine. These very early varieties should be grown in a house by themselves, so that when the stoning is completed the fruit may be accelerated in ripening by an increased temperature, but it is not advisable to exceed 65° at night, or 70° to 75° by day from fire heat, because the growths are liable to become attenuated when the atmosphere is warm, close, and moist. It is different under sun heat, as evaporation is going on, and assimilation taking place to a much larger extent; therefore the temperature may be kept through the day at 75° to 85° from sun heat, ventilating at the top of the house at 75°, and opening the front at 80°, so as to secure a circulation. To prevent moisture being deposited on the fruit and "spot" induced, it is advisable to leave a chink of air at the top of the house constantly. Close the house at 80°, and sufficiently early to allow of a rise to 85° or 90°, the trees being syringed, and surfaces well damped so as to secure atmospheric moisture, which will cause the fruit to swell to a great size, Alexander and Waterloo reaching 10 inches in circumference. Employ clear rain water, and have the fruit dry before nightfall. Syringing the trees must cease directly the fruits commence ripening, otherwise their skins may become rough or cracked, and then they are spoiled in appearance and have a musty flavour when ripe. A genial condition of the atmosphere should be maintained for the benefit of the foliage by damping available surfaces twice a day, and keeping the mulching on the borders moistened as it becomes dry.

The second early varieties, Hale's Early, A Bec, Early Alfred, Dr. Hogg, and Rivers' Early York Peaches, Rivers' Early, Lord Napier, and Goldoni or Darwin Nectarines, started in December, have scarcely finished stoning, and they must not have a temperature exceeding 60° to 65° at night and 70° to 75° by day with gleams of sun. Allow 5° to 10° more from sun heat with a free circulation of air. Stirling Castle, Royal George, Dymond, and Crimson Galande, all Peaches carrying a

high colour combined with first-class quality, and unrivalled for forcing, all points considered, are still later in stoning, as also are Stanwick Elruge, Dryden, and Humboldt Nectarines; therefore when a number of varieties are grown in the same house the temperature must be regulated so as to suit the later varieties. Pay particular attention to the watering; keep the border mulched with sweet, rather lumpy manure about an inch thick, and afford liquid manure when necessary, or top-dressings of fertilisers washed in, but avoid encouraging sappy growths by excessive and needless supplies. Stop or remove all gross growths, they have time to draw the supplies of sap from the weaker parts of the trees, but allow leading shoots, particularly of young trees, to extend over uncovered parts of the trellis, pinching out their points when the fruits begin to take the last swelling, or they may be left their full length when sturdy and short-jointed. Remove the leaves over or in front of the fruit, and turn the latter up to the light by thin laths placed across the trellis with the apex pointing in the direction of the most light, so that the colour may be there most pronounced and the fruit highly flavoured.

Disbudding and the shoots that are to succeed those now fruiting having been properly attended to, there will not be any more growths than are necessary for next year's bearing, the extension of the tree, or for attracting the sap to the fruit. Gross shoots are best removed, as they appropriate an undue amount of sap, often fall a prey to gumming, and cause unequal vigour in the branches of the tree. Pinch laterals at the first leaf. Shoots retained to attract the sap to the fruit ought to be stopped in the first instance at three or four joints of growth. Endeavour to provide an equal distribution of foliage that will shade and protect the strong wood from the direct rays of the sun as the season advances, as they are liable to become sunburnt or dried, and the channels that convey the sap are thus contracted. Besides, such condition invites attacks of the Peach-boring Woebertian moth caterpillar. Avoid overcrowding the foliage, not permitting more shoots than can have full exposure to light and air.

Ventilate early but carefully, avoiding depressions of temperature and cold currents. Thin the fruits where too thickly placed, not overdoing it. With the trees in good health and not too luxuriant the prospect of stoning a full crop of fruit is more likely than when the trees are overburdened, whilst deferring thinning only takes so much size from those fruits that are ultimately allowed to remain for the crop. Inside borders must be duly watered, and may be mulched with short sweet stable manure, but not too fresh or too thick.

Trees Started in February.—In disbudding the strongest parts of the tree would be commenced with, and a shoot reserved at the base of the current year's bearing shoots. A growth on a level with or above the fruit must also be retained on each bearing shoot, and be pinched at three or four joints, leaving no more extensions than are necessary for furnishing the trees with branches, which should be 12 to 15 inches apart. On last year's extensions the growths for next year's bearing should be left 12 to 15 inches distance apart. Attend to thinning the fruit, removing the worst placed, reserving a few more only than will be required for the crop. One fruit to every square foot of trellis covered by the tree is ample, but vigorous trees may have the fruit left a little closer, and weakly trees be correspondingly thinned. Syringe early on fine mornings, admit a little air shortly afterwards, gradually increasing the ventilation with the sun's heat, and syringe the trees again about 3 P.M., closing the house so as to insure a slight rise from sun heat.

Trees Started Early in March.—As the blossoming is over recourse may be had to measures for the destruction of insects. Fumigation must be carefully practised, as the tender foliage and young fruits are highly susceptible to injury, an overdose skeletonising the leaves and causing the fruits to fall. Similar remarks apply to insecticides, which, if used too strong, may prove as injurious to the leaves and crop as to the insects. Syringe the trees in the morning and early afternoon on fine days, whilst in dull weather an occasional syringing with damping of the paths and borders will suffice. Water inside borders as required, always affording enough when any is needed to thoroughly moisten the mass of soil through to the drainage. Proceed with disbudding gradually, a little each day, and observe the same rule in thinning the fruit, rubbing off the smallest and badly placed as soon as the most prominent show signs of taking the lead. Ventilate freely on all favourable occasions, closing early with a view to utilising the sun's heat.

Latest Houses.—The trees in most cases are in blossom, and this profits by free ventilation, insures sturdiness and high concentration on the parts developing. Merely use fire heat to exclude frost, and to allow ventilation during the day. When the anthers show turn on the heat in the morning so as to raise the temperature to 50° by 8 A.M., and keep at that through the day with a gentle circulation of air, turning off the heat early in the afternoon, so as to allow the pipes to cool before night, and the temperature falling to its night minimum of 40° to 45°. This is quite safe, and ought to be secured after the blossoms expand with a little air to prevent the deposition of moisture through the night on the flowers. Impregnation may be effected by shaking the trees, dusting the flowers with a rabbit's tail mounted on a small stick, a camel's-hair brush, or a plume of Pampas Grass, but the best aids to a good set are free ventilation and a genial atmosphere.

Unheated houses or wall cases should be very freely ventilated in bright weather, but when the petals unfold it is necessary to secure a genial temperature by day, ventilating at and regulating it so as to secure a heat of 50°. As a safeguard against frost the house may be closed rather early enclosing sun heat up to 65°. Do not use water for

damping down after noon, and this will prevent moisture condensing on the flowers through the night, or a little air will allow it to escape. Scrim canvas or other material over the roof is useful on frosty nights.

THE FLOWER GARDEN.

Gladioli.—If the corms are kept out of the ground much longer the probability is they will either fail to start strongly or the plants be too late to flower properly. Corms may be planted in the open ground now, and others for succession not later than the end of April. They pay well for liberal culture, and seeing how cheaply handsome varieties can be bought, there is little excuse for their not being grown in every flower garden. If wanted particularly good, they ought to be grown by themselves on well-manured, deeply dug ground, each corm surrounded with silver sand and a little fresh loam. They ought to be buried 4 inches below the surface, and may be arranged 9 inches apart in rows 1 foot asunder. In mixed borders plant either in groups of three or singly. Gladioli are very effective in beds dotted among Mignonette, Heliotrope, and other low growing flowers.

Herbaceous Lobelia.—These tall-growing species, of which Queen Victoria and cardinalis fulgens are two of the best, make the finest display if the seed is sown in June and strong plants prepared and wintered in frames for turning out early in May, but much may also be done by dividing old stools now. If these have been kept in a cold frame, they may now be split up freely, every young shoot being furnished with roots at the base. Either temporarily bed them out in frames or pot them singly, and strong, well-established plants may be had by bedding out time. The crimson stalks and foliage are effective, and late in the summer the spikes of scarlet flowers highly attractive. The plants cannot well be too liberally treated at the roots.

Hollyhocks.—Old stools wintered under glass should now be sufficiently advanced for dividing, every young growth furnished with roots being potted singly and kept in gentle heat till well established. Cuttings taken off with a heel, placed separately in 2½-inch pots, and set on a warm flue or the staging very close to hot-water pipes, will root in the course of three or four weeks, but will damp off if kept too close and moist. Any that have been already rooted should, before they are root-bound, be given a shift into 5-inch pots and kept in gentle heat for a time. Seedlings raised early may be grown sufficiently strong to flower late in summer, but they must be kept steadily growing till they are planted out in well-prepared borders.

Sweet Peas.—These are highly valued, and more than ordinary pains have to be taken in raising a supply of plants. This season the seed is of an inferior character, that of choice varieties germinating badly, even in heat, and it is so expensive that it is unwise to risk sowing it in the open, unless the soil is of a warm light character. Plants raised early should be hardened, and more seed sown in 3-inch pots. A group of from five to eight plants well isolated and duly supported will thrive and flower far better than when crowded into rows. Make a successional sowing of common varieties where they are to flower. Give them plenty of manure at the roots, water freely in dry weather, and they will continue to flower abundantly till frosts intervene.

Sunflowers.—There are now quite a large number of annual Sunflowers, including both single and double flowering, tall and dwarf varieties. The more robust of them may be sown where the plants are to flower, this being done late in April; but as they transplant readily, raising under glass is the plan generally adopted, and is really the best for the more delicate varieties, including the charming New Miniature. Sow the seed thinly now or before the end of April in pans or boxes, placing these in gentle heat. Raised thinly and not unduly forced the plants will be sturdy, and there will be no necessity to pot them off.

Balsams, Ricinuses, Grasses.—The first named can be raised in the open, the seed being sown thinly in patches where the plants are to flower not later than the first week in May. A stock will, however, be obtained with greater certainty by sowing the seed in pans and placing these on a warm greenhouse shelf. If the soil is shaded and uniformly moist the plants will soon appear in a sturdy form for potting singly. Ricinuses are also easily raised, and a few of these noble plants are very effective in the pleasure grounds. From the middle to the end of April is soon enough to sow the seed, as it germinates in a few days, strong plants being easily prepared for the open in a month. Sow singly in 3-inch pots, place in heat, and keep the plants near the glass. Give a shift before they become root-bound. Ornamental Grasses may be sown now thinly in patches where they are to grow, and according to their respective heights, or they may be raised in boxes in gentle heat, and duly moved out in patches. Their requirements are of the simplest description, crowding the plants being the mistake most often made. Now is a good time to sow Zinnias under glass.

Sowing Hardy Annuals.—If the borders were duly manured and in good condition there should be no further delay in sowing hardy annuals, including Alyssum, Candytuft, Collinsia, Chrysanthemums, Convolvulus, Calliopsis, Godetias, Helichrysums, Larkspurs, Linums, Malopes, Mignonette, Nasturtiums, Nemophilas, Poppies, Sweet Sultans, Tropæolums, Venus' Looking Glass, Virginian Stock, Hibiscus, and such like. Fine down the soil, moisten it if at all dry, form circular patches, and sow the seed thinly, according to the catalogue heights of the varieties. Place a peg or label to each, and cover with fine sifted soil. Keep a good look out for slugs, trapping or otherwise destroying these before they play havoc with the seedlings.

THE BEE-KEEPER.

SEASONABLE NOTES.

THE influence of wet weather, when accompanied with a low temperature, is most detrimental to bees at this season, and the past month has been unsatisfactory from a bee-keeper's point of view. High winds and cold showers of snow, hail, and rain have prevailed throughout the month. The total rainfall was 2.53 inches, which fell on twenty days. Only on a few occasions, during short spells of sunshine, have the bees been able to venture far from their hives, thus showing the great advantage derived from having early producing pollen-bearing plants within a short distance of the apiary. The bees are then able to obtain all that is necessary from a natural source. This is a much better plan than supplying them with artificial pollen, but there are many bee-keepers who are not able to utilise the most useful plants and trees for the future requirements of their bees. It is then an absolute necessity to supply artificially, as stocks will make little headway unless pollen is coming in freely.

Pea meal or ordinary Wheat flour makes a capital substitute. The best plan is to place it in the open air daily when the bees are on the wing. If placed in a vessel containing a few shavings, to which the bees may be enticed with a little liquid honey or thin syrup, they will take it readily; or if a small quantity is dropped into some fully expanded flowers which bees frequent, it is surprising how rapidly they will clear it out and carry it to their hives.

Bees on the whole are very backward, and unless a change soon set in they will not be in a good condition for the fruit blossoms. This is not to be wondered at when one takes into consideration the wet weather experienced throughout the country during the past six months. The first three months of last year was in marked contrast to the present season. The rainfall being light, fine weather prevailed, bees were daily on the wing, and stocks increased rapidly; but owing to a cold spring and a dry summer it was not a good honey year (except in a few favoured localities), showing that however good the early months of the year may be, all will depend on the weather and the condition of the bees when the honey flow comes.

An early harvest cannot be expected this year, as many of the stocks have less bees now than they had a month ago. Should a favourable change in the weather set in colonies headed by young fertile queens will increase at a rapid rate, and will doubtless soon make up for lost time.

SPRING DWINDLING.

To guard against this it is advisable to know the condition of each individual stock. If each hive is numbered, as has been often advised in these pages, it is a simple matter to make a note as to their requirements, and due attention given to them, as spring dwindling is frequently caused through shortness of stores; and with the advent of April it is quite safe to feed with thin syrup in preference to candy, as however carefully the latter may be made there is always a certain amount of waste in connection with its use. The bees will abstract the moisture from a portion of it and carry the dry pieces of sugar that remain out of the hive. But with syrup there is no waste, though it is not advisable to use it at midwinter.

Thin syrup, for spring feeding, may be made in the proportion of 1 lb. of sugar to a pint of water, boil until the sugar is dissolved, and it will be ready for use; a pinch of salt and a spoonful of vinegar stirred into it will be an advantage. The bee-keeper's aim should be to keep the bees as warm as is possible. By using a float-feeder on the top of the hive it is almost impossible to prevent an escape of heat from the brood nest, and for this reason it is advisable to use a bottle-feeder for some time to come; the temperature of the hive will then not be interfered with. Have an ordinary honey jar, and partly fill it with warm syrup, and tie a piece of muslin tightly over the mouth; cut a hole the same size through the quilt, and insert a piece of perforated zinc to prevent the bees escaping whilst the bottle is being refilled; invert it over the aperture, and cover with several thicknesses of old carpet or similar material, and the bees will take it readily, and if continued until the natural supplies are coming in freely little spring dwindling will take place, although it is very prevalent where careful attention is not given to the bees.

OPEN AIR FEEDING.

This is an easy way of keeping the bees supplied with stores during favourable weather at this season, but it is only recommended when there are no other bees in the district, or when the

bee-keeper does not mind his neighbour's bees having a share with his own. I often practise it, and the bees will take it freely if placed near their hives. It has the advantage, too, of being little trouble. A few shallow saucers are required into which are placed a few shavings or thin strips of wood to prevent the bees being drowned. These are put within a few yards of the hives, and filled with thin syrup as often as required. It is not advisable to do this too early in the season, or it will encourage robbing, but after this date I have not been troubled in that respect.

In large apiaries, which are isolated in the country from other bees, or in solitary hives in country gardens, I can strongly recommend this plan where bees are at all short of stores. However carefully stocks of bees may be fed in the autumn there will be some that require feeding at this season.—AN ENGLISH BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

G. Bunyard & Co., Maidstone.—*Herbaceous Plants*.
W. Clibran & Sons, Altrincham.—*General Catalogue*.
F. R. Pierson & Co., Tarrytown-on-Hudson, New York.—*Seeds and Plants*.
F. E. Young, Rochester, New York, U.S.A.—*General Tree List*.

* All correspondence relating to editorial matters should be directed to "THE EDITOR." Letters addressed to members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return rejected communications.

Rose Cups and Tubes (A. M. M.).—The cups and tubes used by the members of the National Rose Society is Foster's, which may be procured from any horticultural dealers. The patentee is Mr. Foster, Ashford, Kent.

Dimensions of a Tennis Court (E. R.).—The following are the measurements:—Extreme length, 78 feet; width, 36 feet; inner court, 42 feet long, 27 feet wide, divided lengthways by a white line and crossways by a net. Your rough sketch is correct.

Chrysanthemums from Suckers (T. H. B.).—The healthy suckers with roots attached, if potted, placed in a frame, judiciously watered and shaded for a time to prevent the leaves flagging, will, under good management, make useful decorative plants in the autumn. If you have in view exhibition blooms, such plants cannot be expected to produce them "as well as if cuttings were taken at the proper time."

The New Vegetable "Chayote" (Mrs. M., Wimbledon).—We have been successful in discovering the botanical name of this perhaps over-extolled vegetable through the great seed firm of Messrs. Vilmorin and Co., Paris, and as we have seen the vegetable grown in England and tasted its "fruit," as that is the part eaten, we hope to reproduce an illustration of it in an early issue. It has another fanciful name in England.

Orchid Book—Microscope (N.).—"Orchids: their Culture and Management," by Mr. W. Watson of Kew, is an excellent work. The publisher is L. Upcott Gill, Strand, London. "Barberry's Orchid Book," published by Blake & Mackenzie, Water Lane, Liverpool, is lower in price and thoroughly reliable. Write to Messrs. Negretti & Zambra, Holborn Circus, London; or Messrs. Newton & Co., Strand, London, respecting microscopes.

Saddle Boiler for Heating Hot-water Pipes (Constant Reader).—We suppose you propose having a plain saddle boiler. To heat 700 feet of 4-inch piping satisfactorily the boiler should be 42 inches long, 18 inches wide and deep inside arch, or 48 inches long, 16 inches wide and deep inside arch, as you may have setting room for a short or long boiler; waterway 2 inches. If a terminal end saddle boiler, which is best for piping over 300 feet, 36 inches long, width (inside arch) and depth 16 inches, waterway usually 2 inches, but that is not material, and is best left to the makers. The heating power is 750 feet of 4-inch piping, better too much than too little.

Caterpillar on Flower-bed Plants (Caterpillar).—It is extremely difficult to advise anything for the purpose, as most substances leave a deposit on the foliage, which is very objectionable in the case of plants in flower beds on the score of appearance, and some are of a poisonous nature, such as Paris green and white hellebore powder, therefore scarcely advisable for use among flowers. If you syringe the plants, or sprinkle them occasionally by means of a watering can with a fine rose in the evening, with an extract of quassia chips, 2 ozs. to a gallon of water, the leafage would be made so bitter as to be unpalatable to the caterpillars. The quassia chips should be steeped overnight in cold water and then boiled for a quarter of an hour, allowing to cool, then straining. Of course, the chips may be placed in a much smaller quantity of water for steeping and boiling; suffice if they are well covered to allow of a good extract, adding the required amount of water. If you add softsoap at the rate of 1 oz. per gallon of water, dissolving in the hot extract as it cools, it will adhere better to the foliage, and be even more objectionable to the caterpillar, as also to the eye, for it leaves some deposit on the leaves. If you do not mind that add 1 oz. of freshly ground white hellebore powder to each gallon, mixing well. This is a poison, but it soon loses that property, and is not dangerous.

Plum Growths and Blossom Blighted (F. W.).—The young leaves and the blossoms are badly "blighted," as you say, but not by either insects or fungi, for the flowers are perfect in ovary and stigma, also stamens and anthers, where the petals are more or less damaged. True, in some cases, the whole flower is killed, and the agent has been frost. This has been the cause of the mischief so far as the browning is concerned, but the blossom altogether is very puny, and may be a consequence of very heavy cropping in previous years. We examined the growths and flowers very carefully for insects and fungi, and only found two scale insects and one thrips, the latter a black one (*Thrips minutissima*) which certainly could do little harm, there not being any trace of injury from that source on either the growths or flowers. Of cryptogamous plants there was only a little moss, and that of no material consequence. We see little to call for remedial measures, but you may spray or syringe the trees with a solution of soluble petroleum, which can be readily made by dissolving 1½ lb. softsoap in a gallon of water by boiling, and when dissolved and boiling remove from the fire and add 1 pint of petroleum, stirring briskly with a switch made of an old birch broom until thoroughly amalgamated, and then add hot water to make 10 gallons, mixing well, and when cooled to 90° to 100° apply either with a spraying apparatus or syringe. This may be done as soon as the trees go out of blossom, and it will make end of the scale and thrips, or, if any, aphides and red spider, also the moss.

Tomato Leaves Mottled (W. L. H.).—We subjected the specimen to a careful examination, and found nothing but a few outgrowths here and there of the conidial condition (*Botrytis cinerea* var. *sclerotiphila*, Mass.) of the smother Potato fungus (*Sclerotinia sclerotiorum*), of which you need not feel alarmed, as you have used fostite and sulphured the hot-water pipes, both excellent methods, only do not employ so much fostite as to needlessly coat the fruit, the lightest possible dusting sufficing. We would, however, urge early ventilation, some always, so as to prevent moisture settling on the foliage and fruit. With this and the steps taken you may defy the parasite, which certainly cannot live in a comparatively dry atmosphere. 2. To prevent any injury at the roots, and fortify the plant inside, you may use Little's soluble phenyle, which may be had by order through any chemist throughout the world, or direct from Messrs. Morris, Little and Son, Ltd., Doncaster. The proper strength to apply to the roots is 1 part in 96 parts water = 1 gill (¼ pint) soluble phenyle to 3 gallons of soft water. It is a fertiliser as well as a germicide and eelwormic de, also miticide. It is not advised for the tops. 3. Superphosphate of lime should be sprinkled on the surface of the soil and scratched in, or, if that is not possible on account of the roots, cover with a little soil, only a very small amount, or it may be washed in. If used as a liquid do not use more than 1 oz. per gallon of water, better too weak than too strong.

Variegated Patches on Tomato Leaves (Festina Lente).—We have microscopically examined the leaves and discovered no disease in the yellowish patches, which appear defective only in respect of chlorophyll, and that simply localised to a small portion of the leaflet surfaces. This occurs on a great variety of cultivated plants, especially Potatoes and Tomatoes, but from what causes it arises has not been satisfactorily explained. It is certain, however, that disease often begins at such places, hence may be regarded as relative weakness as compared with the other parts of the leaves. Indeed the spots often spread and cause the whole leaf to become similarly affected, and that without trace of any micro-organic or visible agent; otherwise the leaves are very healthy, but rather deficient in substance, and certainly would be benefited by more air, not so much to check growth as to secure stouter texture and a more floriferous habit, which is also most disease-resisting. We would also advise the use of fertilisers of a moderate ammoniacal or nitrogenic nature until the fruit is set and swelling, such as dissolved bones 3 parts or lbs., double sulphate of potash and magnesia 2 parts or lbs., nitrate of soda 1 part or lb., and sulphate of iron ¼ part or lb., mixed, using about 4 ozs. of the mixture per square yard, omitting the nitrate of soda until the fruit sets; then it can be supplied very advantageously, as with the plant stored with phosphoric acid and potash the nitrogen will be much better utilised. Of course the nitrate of soda can be employed when growth is wanted, but it rather hinders than favours fruitfulness. The flagged leaves recovered, except at the tips of the leaflets, and in the tissues of these we failed to discover any fungal hyphæ, so that the plants if affected at all by drooping disease

fungus, sometimes *Fusarium solani* var. *lycopersici*, at others by *Sclerotinia sclerotiorum*, are so at the roots; even Potato fungus, *Phytophthora infestans*, may be carried over in the seed. This shows why some plants collapse under conditions that appear to favour others, the sole difference being that some are infested and the others quite clean. The only safeguard against this is very careful selection of seed from perfectly healthy plants.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, at being often difficult to separate them when the paper is damp. (*Telmah*).—To name plants from such scraps as you have sent is an impossibility. Send fresh ones packed properly, and we will gladly assist you. (*Salix*).—1, *Salix alba*; 2, *S. fragilis*; 3, *S. viminalis*; 4, *S. Caprea*; 5, *S. purpurea*. (*W. M. G.*).—*Sparaxis tricolor*.

WHO GETS IT?

NOT the lawful owners, of that we have been quite sure for a long time, but it is the way of the world; the weakest always go to the wall. The work of individuals is swamped by the work of

the mass, and it is only by combination, and presenting a face set like a flint, that the rightful owners get their due. Farmers are robbed on all sides; they have long odds to contend with—bad seasons, bad prices, and over-production, but the greatest obstacle to their own advancement is to be found in themselves. When a man's foes are those of his own household, the situation is at its worst. There appears to be no known method or scheme that will bring about among farmers a spirit of co-operation. Like the revolutionaries in Ireland, there is always a traitor to be found in the camp, and the scheme is strangled in its very birth.

Who gets the profit accruing from the milk trade? In towns and thinly populated districts the milk trade is brisk, and the demand for the really good article great. But why is it that the B.D.F. is brought almost to the verge of ruin? What are the causes, and what, if any, are the remedies suggested? "Sweet are the uses of adversity," and if adversity will open the eyes and enlarge the mind it has fulfilled its mission well. Mr. Sheldon says, "The milk trade is under no management whatever; on the producer's side that involves the employment of a comprehensive system of co-operation. This is the universal weak spot of the milk trade—the want of regulation. The trade is like the rabble of an army, entirely destitute of battalions and regiments. . . . The whole thing is without cohesion, regulation, organisation, or system; it is, in fact, limp, loose, and invertebrate to a degree—a degree, however, that makes its weakness a certainty, and, at the same time, a constant source of loss." It is always hopeless to expect the milk trade to become organised so long as farmers had no obvious leaning to co-operation.

It is a curious thing, but while a man will freely tell his rent, the amount of his wife's fortune, the price received for most of his farm produce, he keeps a still tongue in his head when the question of milk contract comes uppermost; it is a secret known only to himself and the dealer. There must be something wrong when a farmer only receives 2d. per quart, for that milk which is afterwards retailed in London at from 3d. to 5d. per quart—the much larger quantity at the greater price. Are we obliged to submit to this? Of course we know that the retail dealer has working expenses and bad debts, but has the farmer never a bad debt? We think we have heard of a good many dealers who have failed to come up to time, and there was no getting back the lost milk.

"Defence, not defiance," is as good a motto for the dairy farmer as for our standing army, and we are glad to see that at least a section of the profession are taking steps to prevent themselves being further mulct of their profits. We allude to the farmers of Staffordshire and Cheshire. Naturally the Cheshire men will look to their cheesemaking to relieve them of surplus milk, or rather to use milk for that purpose when it cannot be sold at a decent profit. Can any other opening be found for that milk which cannot be sold or turned into cheese or butter? We think so. When we speak of cheese, we mean the ordinary hard-keeping cheeses. Now there are several soft cheeses seen only on the tables of the well-to-do which would make a charming addition to the bill of fare of the million. They are not difficult of manufacture; they do not require much plant, and can be sold at a popular price.

Some of these cheeses have been made most successfully at the local technical classes; indeed, we fancy there is hardly now a district in England where the "soft cheese" teacher has not been. Three cheeses here mentioned are made of new milk, and all are ready to use within the week. We refer now to "the Cambridge," "Coulommiers," and Gervais cheeses. Then, again, we have known a good trade done in the old-fashioned cream cheese, an article most easy of manufacture, and which leaves a nice living profit. Let the million have these cheeses set before them, and we guarantee there will be a market for them. How many a tired-out housewife will find in them an excellent substitute for the everlasting pudding. Which is nicer in warm weather, a piece of sweet mild cheese or

some of the "stickjaw" compositions seen on the middle-class table, and dignified by the name of the "sweet course?"

All this time we seem to have lost sight of the real owners of the milk. Well, says one, has not this article been all about the dairy farmer? Soft and fairly, my friends, not so quite. What business have we to take away the birthright of the calf? We do not hold with substitutes for milk—we know by experience that our best stock is that we have reared ourselves on good wholesome milk supplied directly from the mother to her offspring, but here we go one better than Nature. We give our cows two calves to rear—sometimes three. We give the cow the best of all good food, and she repays us in this way, by bringing the calves to first-rate condition and keeping in good condition herself. Breeding stock has paid and will pay in more ways than one.

There is nothing that beats good pure-bred stock, and how can any trust to pick up what he wants in the market? We still find, bad as times are, that our butter meets with a ready sale, and we know our pigs are capital machines for turning the old milk into prime bacon and ham. Good meal, a few "taties," and all the old milk the dairymaid can be induced to spare, will, if put into a growing pig's skin, make a good profit and quick return.

WORK ON THE HOME FARM.

The past week has been a favourable one for farm work. We have had only one wet day, and that has done more good than harm for the sodden ground so suddenly drying was working up rather rough, and the rain has had a good effect on the hardening clods. Sow, drill, or plant have been the order of each and every day, and good progress has been made. We are not sure that the present is not the busiest time of the farm year. The drilling of grain and planting of Potatoes, the sowing of small seeds and preparation of land for Mangold operations, all condensed into four or five weeks, at a time when sheep and cattle are requiring more labour and attention than at any other period of the year, make the seedtime a very anxious one for the tiller of the soil.

Sheep are coming off Turnips, and will have Mangolds on grass until clipped and sold. They will not bear to be too closely penned up when eating Mangold, as they are better for a little exercise, which prevents the excess of sugar in the Mangold from bringing on urinary complaints.

Grass has grown very fast, and pastures are now giving a nice bite. Stockowners did not require much reminding that it was time to turn their cattle out, and many fields are now stocked.

Fallows are turning up very rough, and require the drag harrow and roll very closely after the plough if a fine tilth is to be secured. If the land is clean, we prefer ploughing again after a few days' exposure to the sun and wind. This only applies to the medium and heavy soils; for light ones there is nothing better than a repetition of drag, harrow, and roll until the land is clean or wanted for Turnips.

Mangolds should be drilled at once on warm and dry soils where they will be safe from frost. The soil must be in fine condition, or the seed will not germinate; but to make safe of it growing it may be steeped in water for twenty-four hours, then drilled, with the help of a few fine dry ashes to keep it from clogging in the drill; 6 lbs. per acre is a good quantity, some sow less, but we think it is risky, and the Mangold crop is too valuable to play tricks with.

REMARKS.

- 28th.—Rain from 3 A.M. to 6 A.M., and 10 A.M. to 11 A.M., and storm rain at 7 P.M.; overcast and windy day, but gleams of sun.
 29th.—Brilliant early; alternate sunshine and cloud during day.
 30th.—Fog early with sun visible, clearing gradually, but hazy all morning; bright afternoon.
 31st.—Overcast, with frequent spots of rain in morning; alternate showers and sunshine in afternoon.
 1st.—Wet snow till about 10 A.M., and damp all morning; bright sun from 3.30 P.M.
 2nd.—Fine with frequent spells of sunshine.
 3rd.—Overcast day, with spots of rain at times.
 An average week for the season, with sharp grass frosts on several nights.—
 G. J. SYMONS.

BARR'S "LIGHTNING" RUNNER BEAN
A valuable acquisition, bearing in abundance clusters of pods, remarkably early, and of delicate flavour. Per Half Pint, 2/-.

BARR'S MONSTROUS LONG-PODDED BROAD BEAN.
The earliest, largest, and most productive of long-podded Broad Beans, and of fine delicate flavour. Per Quart, 2/6; per Pint, 1/6.

BARR'S "LEMON GLOBE" ONION.
A grand exhibition Onion, handsome in form, of large size, mild in flavour, and a good keeper. Per Packet, 1/-; per Ounce, 2/6.

FLOWER SEEDS.—Barr's Specialities for 1897.

NEW LARGE-FLOWERED CRESTED BEGONIA.
A splendid novelty, the large handsome flowers having crested combs, colours brilliant and varied. Per Packet, 3/6 and 5/-.

BARR'S SUPERB FRINGED PETUNIAS.
Flowers of immense size and deeply fringed, colours rich and varied. Per Pkt., 2/6 & 3/6.

BARR'S Extra Selected LONG-SPURRED COLUMBINES.
Mixed, flowers of great beauty in form and colour. Per Packet, 2/6.

BARR'S NEW SEED GUIDE FOR 1897
will be sent free on application.

BARR & SONS, 12 & 13 KING STREET, LONDON.
Nurseries at LONG DITTON, Surrey, near to Surbiton Stn., S.W.R.

RICHARD PANNETT, Florist, Chailey, Sussex,
Begs to offer DAHLIAS, 3s. per doz.; NEW FUCHSIAS, 9d. each; ditto of 1896, 4s. per doz.; CARNATIONS, 6s. per doz.; NEW ZONALS, 7s. per doz.; ditto of 1896, 4s. per doz.; all in first-class varieties. Postage 6d. per doz. extra. See Catalogue, which contains full directions How to Grow, Show, and take Prizes. Exhibitors would do well to consult this Catalogue.

BEGONIAS.

Double and Single, Gold Medal Collection, for Conservatory and Exhibition, the largest and best in the trade. See Catalogue. **BEGONIAS FOR BEDDING**, superb quality, Double, 6s. and 9s. per dozen; Single, to colour, 5s. per dozen, 35s. per 100; 10 colours mixed, 4s. and 28s.; fine mixed, 3s. and 2s.

150 ACRES Of Trees & Shrubs.

In the finest possible condition for the Villa, the Mansion, the Plantation, or the Game Covert. All in vigorous, healthy condition, not stunted, starved, or closely grown and drawn. Carefully and frequently moved, and the roots consequently are a mass of fibre, ensuring safe removal when sold.

NEW CATALOGUE, with descriptions of above, and of many Rare and New Plants. Post Free from

CLIBRAN'S Nursery, ALTRINCHAM
Also at Manchester, Bangor, and Llandudno Junction.

LILIUM AURATUM.

The beautiful golden-rayed Lily of Japan. Magnificent for pots in the greenhouse, or for growing in the open garden. Deliciously scented, quite hardy. Planted now will bloom splendidly during the summer and autumn. Extra fine roots, 10 to 11 inches circumference, per doz., 7s. 6d.; 6 for 4s.; or 25 for 14s. Grand selected roots, 11 to 13 inches circumference, per doz., 12s.; 6 for 6s. 6d.; or 25 for 21s. All post or carriage free for cash with order.

DANIELS BROS., Town Close Nurseries, NORWICH.

CARNATIONS.—Clearance Sale.

A grand collection of choice named double flowered, in beautiful variety, including all the finest sorts. Strong plants from single pots, correctly named, per doz., 4s. 6d.; six for 2s. 6d.; or 25 for 8s. Double crimson Glove, deliciously scented, per doz., 3s. 6d.; six for 2s.; or 25 for 6s. 6d. Packing and carriage free for cash with order.

DANIELS BROS., Town Close Nurseries, NORWICH.

CHRYSANTHEMUMS. CLEARANCE SALE.

A splendid collection, including all the most beautiful and popular of the Japanese and incurved varieties; strong, well-rooted cuttings, correctly named, per doz., 1s. 6d.; per 100, 10s. 6d. Extra choice sorts, per doz., 2s. 6d.; per 100, 15s. Six grand new exhibition varieties splendid, the set 3s. 6d. All post free.

DANIELS BROS., Town Close Nurseries, NORWICH.

FUCHSIAS.—Clearance Sale.

A magnificent collection of superb double and single flowered varieties, including the newest and most beautiful sorts in cultivation. Splendid for pot culture or the garden. Strong young plants, from single pots, correctly named, per doz., 2s. 6d.; six for 1s. 6d.; or 25 for 4s. 6d. Extra choice sorts, per doz., 3s. 6d.; six for 2s.; or 25 for 6s. 6d., post free.

DANIELS BROS., Town Close Nurseries, NORWICH.

FERNS A SPECIALITY.

We have an immense stock of all kinds of Ferns, Stove, Greenhouse, Filmy, Hardy Exotic, and British, including many very beautiful varieties, rarely seen but which ought to be more generally grown. Catalogue free on application.

Journal of Horticulture.

THURSDAY, APRIL 15, 1897.

ALTERATIONS.

AFTER nearly forty years of occupation by the *Cottage Gardener and Journal of Horticulture*, the premises of 171, Fleet Street need and must have thorough renovation; the nature of the alterations which have been decided upon are extensive in scope, and some months must elapse before they can be completed. The preparatory work will be no small item, for, from cellar upwards, the building must be cleared of its contents; tons of blocks for illustrations and tons of books, all must be removed. The accumulations of years must be examined, sorted, and classified as useful and useless, and dealt with accordingly—then follows the structural work.

A new roof is to be provided, and a new staircase from the bottom to reach it, and all the several floors on the way. How, then, can the routine business of editing, type-setting, and all the rest be conducted? It simply cannot be conducted there, and an exodus is imperative. The compositors will troop down the ten flights of stairs this week for new quarters already procured not so near the clouds. The Editor has provided for himself, preferring the suburbs and the breezes from the Surrey hills to the City, so densely packed as it will be during the coming summer. The publishing department and advertisement contingent must perforce follow as soon as the head of all can find them, as he hopes, something like a quiet retreat outside the hurly-burly of the great thoroughfare with all the crush and bustle and din for which it is notorious. By-and-by it will be necessary, when the matter is settled, to make the chosen locality known for the usual business purposes.

In respect to the Editorial department, there can be no waiting. The young lions are panting to be out of the Fleet Street den, and the old one must perforce go to keep them in order. Before the week is out they will be in the southwestern wilds, with all their paraphernalia; and thus it is that all those readers who are likely to seek advice on gardening matters, or who may wish to send flowers to be named, eelworms to be examined, mildews to be microscoped, insects to be identified; diseased Tomatoes, Cucumbers, or anything else, to delight Mr. Abbey; fruits to be

No. 2533.—VOL. XXVI., OLD SERIES.

dissected; samples of sickly plants or sound ones; in fact, whatever they may desire to place before the Editor, including articles for publication, from young probationers to old practitioners, from amateurs and gardeners, all should be addressed, not to Fleet Street as usual, but direct to Mr. J. Wright, 8, Rose Hill Road, Wandsworth, London, S.W. They will cost no more, while they will be more quickly attended to than if sent to the old address, and then, as they must be, re-directed.

This notification is made as prominently as possible in the interests of all—readers, writers, editors, and clerks. A few mistakes may occur, but it must be the desire of all that they be reduced to a minimum. "Ah! preparing for the Royal Jubilee," will be the remark of passers-by when the renovations are in progress. Be it so. More will no doubt be heard of the great event before the season is over, and then, all being well, the "Journal" will have a Jubilee of its own next year.

RECORD REIGN SHOWS.

THERE is an unusual amount of activity in every section of society this season to fitly celebrate the completion of the without precedent reign of our beloved Queen, that it would be odd indeed if gardeners, who are amongst the most loyal and admiring and law-loving and law-abiding of citizens, should be behindhand in signalling that glorious reign by every means in their power. We may take it that many horticultural events will be celebrated with greater enthusiasm than usual; that all the customary annual shows will contain either some new feature, some enlargement of benefits, or some alluring and interesting development.

Many new shows will be started, some old ones revived, and some perhaps will strike out on special and original lines. We have evidence of this state of things in your advertising columns this week. I will take two of them—a large one and a small one—of which I have some personal knowledge to illustrate my meaning, and Shrewsbury shall be my large illustration. We all know that as a provincial show this is second to none in ordinary years, but this year, the twenty-second year of its existence, and because of the Queen's record reign, the Society is considerably enlarging its borders, and its show on the 18th and 19th of August is to be a Great Royal Commemorative one to illustrate the advance in horticulture during the sixty years of Her Majesty's reign. The cash prizes offered in the Society's schedules for 1897 amount to nearly £900, with special cups, medals, and other extra awards.

In addition to this, the Royal Horticultural Society are sending down a deputation consisting of the President (Sir Trevor Lawrence, Bart.), and selected members of the Council to co-operate with the officers of the Shropshire Horticultural Society, and to award a gold Banksian and a silver Knightian medal to special productions (particulars of which will be found in the Society's schedule), besides other medals and awards; and the Worshipful Company of Fruiterers (London), are offering their gold and silver medals in the fruit classes; whilst in addition to these the Veitch Memorial Trustees are offering the Veitch Memorial medal and £5, in addition to the first prize of the Society, for a decorative dessert table. Shrewsbury has done great things in past years, but this year will be a record year for it there is not the least doubt. May we all be there to see.

Now, my lesser illustration is the small show advertised in this week's Journal—the Potato Show at Radcliffe-on-Trent, near Nottingham. Having lived at Radcliffe and in the neighbourhood for a good many years, once on a time, I can vouch for the *bona fides* of that advertisement. What the Radcliffe people do, they do well; "thorough" is their motto, and the two gentlemen who have offered the prizes may be relied upon to carry out to a complete success the somewhat unique show, backed up as they are by a band of workers who do not know what it is to fail in anything they undertake to do. Both gentlemen (Messrs. Middleton and Yates) are Potato enthusiasts, and the former, I believe, was not unknown at the Crystal Palace in the days of Mr. McKinlay's Potato shows. The show will assuredly be a very interesting, and should be an instructive one, and I am given to understand that the judging will be on the lines of the R.H.S. code of judging.

These two shows will serve to demonstrate to all whom it may concern that gardeners are not going to be the last in celebrating the record reign of Her Majesty the Queen, a Queen who has, all through that reign, been a good friend to gardeners and gardening.—N. H. P.

OUR HARDY PLANT BORDER.

(Continued from page 224.)

FORGET-ME-NOTS.

WHEREVER any attempt is made to produce a spring or early summer display of hardy flowers the Forget-me-nots are indispensable, and they, moreover, furnish a colour that is all too rare in our gardens. Their graceful habit, and the interesting, even though fanciful, associations connected with the popular name also render them favourites with all garden lovers. The majority have besides a strong practical recommendation to the favour of those who find the maintenance of a varied and extensive display of outdoor flowers a strain on their resources—namely, they are easily increased either by seed or division.

They are mostly adapted for situations where it is sometimes difficult to insure success with other plants, and three positions may be mentioned for which respective groups are suitable—*i.e.*, a rockery or alpine garden, where the dwarf species of *Myosotis*, such as *M. azorica* and *M. alpestris*, will succeed; moist banks or low spots near water, for which *M. palustris* is particularly fitted; and shady shrubbery or woodland path sides or borders, where *M. sylvatica* will succeed. There are special examples of partialities, but *M. dissitiflora*, for instance, will thrive almost anywhere, provided it is not excessively dry, and all the dwarf forms of Forget-me-nots are useful for spring flower beds or borders.

It may be well to point out the chief characters of these species before detailing the culture we have found successful, and the first to be considered is *M. alpestris*. For colour, habit, and general usefulness this deserves a foremost place in every garden, at least that is our experience founded on careful and extensive trials of all the Forget-me-nots in general cultivation. When grown upon a rockery this plant presents the characters of a true alpine, 3 or 4 inches high, compact, with abundant short spikes of flowers, but in ordinary beds of fertile soil it is nearly double the size, though still compact, with vigorous spikes of moderate height, bearing flowers closely set from the apex to the foliage, and produced in such numbers that the plants appear to be almost tufts of flowers alone. The flowers, too, are of good size, a brilliant blue, heightened by contrast with a yellow eye, and possess the additional recommendation of becoming fragrant late in the day. Excellent strains of seed are obtainable of this Forget-me-not, from which thousands of plants can be quickly and certainly raised, and they come so even and true that the slower process of increase by division or cuttings is unnecessary.

Two varieties of *M. alpestris* are, in our opinion, the finest of all Forget-me-nots for spring gardening when they can be had quite true, namely, *Victoria* and *Distinction*. With regard to the former of these, however, we have had some difficulty in securing seed true to character. *Victoria* is an improvement on the common type of *M. alpestris*, being compact, the flowers large, and the colour bright. *Distinction* as we have had it is similar, but if anything more compact and floriferous. Both are admirably adapted for culture in pots for early flowering under glass, a use which is fully appreciated in many gardens where diversity is requisite in the occupants of greenhouses or conservatories. They must, however, have cool situations, for in a moist warm house they are quickly drawn up and spoiled. Two other varieties of *M. alpestris*—*i.e.*, the white and rose coloured, are attractive in some degree, but they are not so well adapted for massing as the blue forms.

Taking it in all its points *M. alpestris* has proved in our experience one of the most useful Forget-me-nots that can be grown in quantity, and we have had no difficulty in procuring seed that produced plants of high quality, equally as beautiful and serviceable as the best selections that receive varietal designations.

Next in importance comes *Myosotis dissitiflora*, though perhaps some would be disposed to give this the first place. Certainly where very early flowering is required it would be most useful; but it is less compact than *M. alpestris*, though a free and continuous flowerer in suitable situations. The flowers are large, rich blue, on spikes a foot or more in length.

For general use in damp situations and heavy soils the common Marsh Forget-me-not, *M. palustris*, is both a charming and serviceable plant, easily increased, of good constitution, and a persistent flowerer. The corollas are large, of a particularly bright blue with a yellow eye, and the plants look well in masses or lines; but it is rather tall for the latter purpose, except in shrubbery borders.

The Wood Forget-me-not, *M. sylvatica*, is usually the tallest of those in general culture, and its looser habit of growth, combined with the fact that the flowers are more distantly placed on the spikes, gives it a rather more weedy and straggling appearance. It

is, therefore, not so well adapted for masses in borders, but scattered amongst trees or shrubs it has a pleasing effect, and succeeds better than most of the others do in similarly shaded situations.

The general culture of the Forget-me-nots already named is simple, and can be summed up in a few words. They are all readily raised from seed, which should be sown at the first convenient time in April, the seedlings being transplanted to their position in the borders or elsewhere as soon as they can be safely moved. A well dug, moist, and fertile soil gives the best results with these specially recommended, and the plants are almost equally pleasing either in masses or lines.

After the first season the perennial species, particularly *M. alpestris*, require to be lifted, divided, and transplanted into fresh soil, and a large stock of strong plants can be thus secured for the current season's effect, March being a suitable time for the operation if the weather be favourable, or it can be done early in the autumn in preparation for the spring work. When a large quantity has been raised from seed some diversity will always be found in the habit, size, and colour of the flowers and the length of the spikes; it is therefore advisable to mark some of the best with labels or sticks for division; a more uniform character is thus obtained, which is important where the plants are employed in lines, but is less requisite in large beds.

On warm soils or in sheltered gardens autumn sowing can be practised with success, and we have frequently adopted this method; but on our cold soil it does not give encouraging results. When grown in large masses some of the *Myosotis* are liable to a fungoid disease of the nature of mildew, which spreads very rapidly, and appears to threaten the destruction of the plants, but with liberal cultivation they seem none the worse the following season, though the loss of so much foliage must be weakening. Fortunately, the disease rarely appears until the flowering is nearly over, but the plants are greatly disfigured afterwards, and a weak application of Bordeaux mixture has seemed to have little preservative effect upon the foliage. A soil well enriched with old manure, or dressed with a light sprinkling of superphosphate early, with nitrate of soda later in the season, the latter being used at the present time for instance, will produce vigorous plants that will give satisfaction in every respect.—A COUNTRYMAN.

PRECEPT AND PRACTICE.

(Continued from page 294.)

AVENUES have been regarded by some of our most accomplished latterday artists as being somewhat of a mistake. It is a question on which ripened judgment will be strong enough to bear the weight of personal opinion. An avenue is certainly one of those daring touches which only a master hand is capable of introducing into his natural picture successfully. There can be no question but what it is a phase of work leaving no margin for those common errors which have entailed from some a sweeping condemnation. The question for us to now consider, like others which through life may often arise, is not of to be or not to be, the onus of that decision probably not resting with us, but the responsibility of laying down the lines on sound principles which we must not evade. I suppose that when, some half century ago, a certain nobleman desired to have an avenue as an approach to his mansion his imagination could never conceive the effect of a double line some half mile in length of Lombardy Poplars in their prime planted in a space so contracted that it was quite a triumph of coachmanship for carriages to pass each other in safety.

Neither could those who planned and planted a century since a short, broad avenue of Elms have foreseen the overpowering effect its matured age would have upon the limited local surroundings. The above are truthful types still existing, and sufficient in themselves to mar the features of the landscape. The latter example, certainly, would not be so bad, as it starts from a noble entrance; but the abrupt finish, owing to the road turning at right angles (to avoid a contiguous property), whence the trees were discontinued, leaves the additional bad impression that the avenue leads to nowhere. In each case the trees are fine specimens of their kind, and one can well understand the feeling which has led successive owners to spare them and tolerate the false position. There is not one of our youngest subjects of bothydom who could not see these and other errors as grave in this direction when developed by time. That is too late—"Too late to mend." Conjure these visions up in your mind's eye, and you will never be guilty of such near-sighted policy.

The carriage road, whether it takes the form of an avenue or not, has, as its name implies, a primary object—it is its right of being; yet we may note examples which seem to exist only upon

sufferance, so undecided are they where to begin, which way to go, and where to leave off. Here is one, however, of a very satisfactory character, and which imparts its full quota of dignity to a gentleman's park. Even a stranger, once within the gates, would feel it unnecessary to ask his way to the mansion, although not immediately visible. Its chief object is to reach the mansion, not as the crow flies, which is, of course, an excellent plan for aerial travelling, nor do its lines follow perversely a number of meaningless petty twists and turns. It is simply what it professes to be, and does simply what it professes to do in the best possible manner. Starting from the lodge gates on open comparatively level ground, for some distance our common-sense carriage drive is fairly straight, for there are no reasons for it to be otherwise until the ground rises nearer to the residence, when it takes a rather wide sweep for a very ostensible purpose, such purpose having been further emphasised by the introduction of some tree groups on the convex side of the curve. Then sweeping up to and past the hall door it continues its sensible course to its exit (or entrance as the case may be) at the other side of the park. Ample accommodation has been left opposite the hall door for those short exercises our waiting whipmen delight to perform, leaving them no excuse for slicing down or cutting up the well-kept verges.

Drives need not detain us long, though their object is to some extent distinct from carriage roads, being the means of conveying the traveller to and exhibiting all the natural beauty of a demesne, and to avoid other points less desirable. Some are so cunningly contrived, that even within a circumscribed area the illusion of having a much greater space and freedom than really obtains is perfect. Unlike our carriage road or avenue, the object of a certain drive which I will attempt to describe is that of being the medium by which at all seasons, and one may say in all weathers, all the most striking natural or created beauty is viewed to advantage. My ideal drive—I must add it bears that name, "The Drive," and appears to be appropriate—runs for several miles in the most satisfying manner, and although it passes in its course through some beautiful bits of woodland scenery, where banks and plantings of flowering shrubs have been freely introduced, the exchange from gravel to grass never prohibits, even in wet weather, the enjoyment of using it, sufficient hard material having been employed in its formation to render this feasible. Through the glen, or following up and mounting to higher ground in graceful curve or graduated incline judiciously planned, peeps are afforded of the outlying country without disclosing the proximity of the boundary, to which, indeed, it is often invisibly near.

The primary study of these free and flowing lines is accommodation to the ground plan—natural formation of the ground. All other matters, essential as they are, are the filling in of that plan by taste and skill in planting, or making manifest natural beauty, of which more anon. We must never lose sight of the fitness of things to their purpose—beauty of purpose, and it matters not whether that has a prior existence or is a subsequent creation of art, the distinctive object in some shape or form must be present, or the purposeless and the puerile court condemnation from the cultured eye. We may note in some instances how caprice alone has misled the designing hand to curve or even double curve S fashion on flat ground, with no apparently ulterior object. Now a curve is very graceful if it has, or has given to it, a reason for existing. There are hundreds of such curves to be found in roads, walks, or paths, begot of caprice and existing on sufferance, which await but a little tasteful planting at the convex side to provide the purpose, the meaning, the object, even though it is an afterthought.

There are very good reasons why these, which are but the narrow suggestions upon a very broad subject, should have the attention of our young gardeners, for I venture to predict that the future will have strong claims upon them in this direction. The fetters of formality which have long tied the gardeners' hands are broken; we are emancipated, and if we choose to call it a new fashion it is one allowing of full and free scope for natural harmony, varied beauty, enlarged ideas. Already, in several places, I have seen the garden flowing over the whole demesne and the gardener running after it, as he should do, making a bog garden here, a rock garden there, planning and planting, sowing, and reaping the fruits of his extended sphere in picturesque gardening. But let no youth think this is any rough and ready method, planned in haste and performed in a hurry, for hasty flights bring ignominious falls. Even plain, natural features are preferable to overstrained specimens of ingenuity, in which characteristic scenery is obliterated and startling incongruities await one at every turn, in which, perhaps, we hear of hundreds, even thousands of pounds being spent. This may be magnificent, but it is not gardening.—AN OLD BOY.

(To be continued.)

FLOWERS FOR SCHOOLS.

If one regard the delight inspired by the presence of flowers, their suggestiveness and influence, there is no more fitting place for them than the elementary schoolroom. Children look at flowers with clean eyes; they are to them a source of wonderment and delight. But that must not be all. "The wisdom of God," says Sir Thomas Browne, "receives small honour from those vulgar heads that rudely stare about, and with a gross rusticity admire His works." One wonders that so few teachers break away, at times, from the thralldom of grant-earning, missing entirely to take their children, in imagination at least, a stroll through "fresh woods and pastures new." I referred lately to a society whose endeavour is to encourage the young to take an interest in the beautiful, limiting the effort to the selection of engravings from the old masters. "Why," I repeat, "cannot these kindly æsthetics present a few flowers occasionally? They would be far more highly appreciated than the costliest engraving of the old masters." But so much the more would they enjoy a simple flower if its structure were explained and understood. If there be one subject, after the so-called essential subjects, that should be taught, in country schools at least, it should be plant life. Not only would such teaching be of direct advantage to those whose probable occupation would be on the land, it would supply the kind of instruction most needed to cultivate the faculty of exact observation and the habit of reflection. Such a subject might be made in the hands of a thoughtful and earnest teacher a really more valuable instrument of education than the so-called three R's.

It is satisfactory to learn that Surrey has started a system of school gardens. But Surrey, it appears, is to the fore in the matter of gardening for schools—"continuation" and elementary. Nearly 500 boys and youths now receive practical instruction on the soil itself, and they appear to be doing excellent work. But to come more particularly to my immediate subject, flowers in the schoolroom. There need be no difficulty with regard to the expense of supplying regularly a few flowers for the teachers' desk. In country schools the children themselves would be pleased enough to do this. I remember an instance in which an elderly teacher, fond of what Charles Kingsley pithily called the "field and wild," would weekly make one home lesson in the season of spring and summer "a collection of wild flowers (named)," leaves of forest trees, grasses, or Ferns. The children would be taught the names, and the structure and peculiarities of the exhibits would be dealt with in a further lesson. If these were of no other use beyond exercising the faculties cited above the lesson would be valuable; indeed to the future farm labourer almost invaluable, while to every villager it would suggest the means of opening up profitable and interesting ways of occupying his leisure. One has heard of that little couplet of Dr. Watts about the unmentionable one finding "some mischief still for idle hands to do." He might search in vain in such a village as I am thinking of for idle hands. Where profit and pleasure are both concerned neither hands nor head are idle.

Far beyond, however, the pleasure of enjoying a flower, its beauty and fragrance, is the knowledge one may gain of its structure and uses. One thinks of Darwin and the Polyanthus. For the better part of a hundred years florists had noticed a difference in the structure of the Polyanthus, raising batch after batch of seedlings, and contemptuously tossing aside those in which the stigma reached the mouth of the tube as "pin-eyed," and cherishing carefully those in which the stamens were longer as "thrum-eyed." There were two kinds therefore, said Darwin, and there is a permanent difference. What is the reason for this? And then, after a long season of observation and experiment, he came to the conclusion that it was to encourage cross-fertilisation and increase fertility.

Another way of encouraging a taste for gardening and the study of plant life was to give each of a score or more boys a single seed of a Sweet Pea, Scarlet Runner, Nasturtium, or Canary Creeper, and offer a small prize for the best plant in a pot raised from the single seed. Many of that old pedagogue's pupils have been grateful for thus introducing them to a source of innocent, healthful recreation and unbounded delight. Some of these fortunate boys are head gardeners now, and although many of their schoolfellows are receiving salaries of £100 a year to their £50, they would be loth to exchange their green lawns, bright sweet flowers, and blue skies for a desk in the clearing house or the railway stations. They would far rather prefer the control and management of a garden than sit all day long on an office stool.

The greatest pleasure to be derived from flowers is by growing them, watching their development from day to day, and attending to their necessities. Nature is full of wonders and problems, and the gardener of all others has the best opportunity of studying

them. There is nothing more marvellous than the germination of a seed and its subsequent growth. I hold in my hand a tiny pellet of starch, enclosed in a vellum case, inert, and apparently lifeless. The germ is asleep, and it is in the power of a child to awaken it and watch its growth to perfection. It is, of course, impossible to grow flowers to perfection in a schoolroom, mainly on account of the dust and impurities of the air. Where there is no stint of light, however, a simple Wardian case might be employed, or a few hardy plants might be grown on the outer window ledge. Then, of course, unless on the ground floor, there might be a difficulty in watering them. A cheap and substantial Wardian case might stand in some prominent position. In this Ferns, a small Palm, and Lycopodiums might be grown; even a flowering plant, Fuchsia or Geranium, might be placed in the case. It would last for several days at least, and add a little colour to the cheerful greenery.

But a more successful effort might be made by the playground walls in growing the commoner kinds of annuals, some of them more beautiful than greenhouse exotics. Some 10 to 12 inches in width of the pavement must be removed close under the wall, to a foot in depth, then some rubble for drainage, and good meadow loam. There should be a 9-inch board, 1½ or 2 inches thick, as a protection, and to hold up the soil. A small-leaved Ivy, a Euonymus, cut in and trained close; or Ampelopsis Veitchi might be planted to serve as a background. These, however, could be dispensed with. Then comes the garniture. Annuals chiefly, though a few bulbs, Snowdrops, Scillas, and Crocuses might be planted, and a few patches of the cheerful white Brassica and Wallflowers. Towards the end of April the seeds of Nasturtiums, Canary Creeper, Convolvulus, and Scarlet Runners could be sown, and either trained to pea sticks, string, or wire. Where there is a will there is a way! This wall garden, as one might call it, should be taken care of by the children themselves under charge of the teacher. In most schools there are children not sufficiently robust as to join in the games with the stronger. The little plots might be cultivated in common, but the better plan would be to allot to each of, say, a dozen volunteers a yard or two, for which the young tenant should be held responsible. I trust to be able to return to this subject.—HERGA.

THE "NEW" VEGETABLE—CHAYOTE.

MRS. MILAND writes respecting the new vegetable, Chayote—When writing before I did so from memory, and have now procured the "Graphic" of March 20th, and forward a copy of the paragraph therein relating to the new vegetable, "Chayotte." I shall be much obliged if the Editor will give any information he may obtain on the subject.

"A new vegetable has been imported from Japan. It is reported to combine the flavours of the Artichoke and the Asparagus, and to be as easily cultivated as the Potato. The French, who are responsible for its introduction, call it 'Chayottes,' and it has already figured largely at the most *recherché* and delicate suppers in Paris. Especially as a salad is this new vegetable to be commended."—"Graphic.")

[Thinking it best to go the fountain head for information, we wrote to the eminent firm of Messrs. Vilmorin-Andrieux et Cie, Paris, who obligingly replied as follows:—"The 'Chayote' is the well known fruit of *Sechium edule* (Cucurbitaceæ) grown in the West Indies, also in Sicily, Algeria, &c., but very little used as a vegetable outside of those countries. Some of the firms here, making a speciality of exotic fruit and vegetables, receive a few consignments of Chayotes every season, and no doubt the note that appeared in the paper mentioned refers to some 'diners' where Chayotes were tested. It has been much vaunted from time to time, but its culture in Europe does not appear to make much progress, if any. We may add that it is a rather peculiar fruit, requiring to be planted whole, the roots starting at one end and the stem at the other. This is all we have to say about the Chayote."

We thank Messrs. Vilmorin & Co. for saying it. According to Johnson's "Gardeners' Dictionary" this "new" vegetable discovered by the "Graphic" correspondent was introduced to this country from the West Indies in 1816. It is also called "Choko"—to fatten, and the Dictionary says "hogs are fed on the fruit in Jamaica." We only know of one place where it is grown to any extent in England, and there it is called "Chou Chou," which is the Cuban name for this plant.

Dr. Hogg has said in his "Vegetable Kingdom" that *Sechium edule* is called "Choko" in South America. "The fruit is green, shining on the outside, whitish and fleshy within, varying in size. Each contains one seed, which is placed at the very top of the fruit, and is sometimes an inch long; when it is ripe it protrudes a little, and puts forth many fibres at the extremity. In many of the West India islands the

inhabitants use the fruit in soups and puddings, or boil and eat it with their meat, as a substitute for greens and Turnips, in which state it is regarded as wholesome and refreshing, but it is too insipid to be much cultivated. There are two varieties of this found in Cuba; one with soft bristles over its surface, and the other quite smooth."

It is evidently the variety with "bristles" that is grown by Mr. Thomas Rochford in his wonderful establishment in Hertfordshire. We had one of the two fruits figured that he kindly cut and presented, the other cooked. The figure is reproduced. The one that was cooked was similar to a full flavoured Vegetable Marrow, and may for all practical purposes, as grown by Mr. Rochford, be described as a winter Vegetable Marrow, for the fruits are produced throughout the winter months.

The plants are trained to the roof of a very large span-roofed house, each when in full growth covering a large amount of space, probably 300 or 400 square feet. The fruits, which are not produced in any great abundance, are usually in pairs at right angles with each other at the end of a string-like stem 15 to 18 inches long. The temperature of the house ranges from 50° to 60°, and the culture might perhaps be profitable if the fruits were sold for half a crown each.

We do not suppose that Mr. Rochford expects them to "pay." With 20 to 30 acres of glass he can well afford to devote a house to the culture of a novelty, so that he may enjoy the luxury (for he is a generous hearted man) of giving something to his friends that they are not very likely to grow at home.

The Parisian fruits, which came in so handy for affording material to the "Graphic" correspondent for a "catching" paragraph, were, as may be inferred by Messrs. Vilmorin's letter, imported, and their flavour when naturally grown in their native habitats for pigs and Parisians may be somewhat different from that possessed by those grown artificially in this country; and, besides, French cooks are so skilful that they can make almost anything good, and add "flavours" to suggest various comparisons. No doubt the *Sechium*, Chayote, or Choko, is "as easily cultivated as the Potato" in its native climes, and we can understand its growing ten times faster and farther, but it is evidently not so grown in France, and is less likely to be so nearly naturalised as the Potato in this country. The "Graphic" might perhaps complete its little sensation by giving an illustration of Mr. Rochford's plants, and astonish its Parisian correspondent.]

HARDY FLOWER NOTES.

A STORMY month was March, and its winds and rains and snow robbed us of much of the beauty of the Crocuses. We thought of them sadly amid the downpour, recalling Herrick's lament over the Daffodils, which, he said, "haste away so soon," or over the Primroses, which "die unmarried ere they behold Phœbus in his strength." Such was the fate of many of the Crocuses. They shielded their precious pollen in their silken cloaks until these delicate and beautiful fabrics were turned into soaked and colourless pulp. We could only look on sadly. A few might be covered, but these were the ewe lambs of the flock. The others had to succumb to the gales and rainstorms. Vain are these regrets. The past cannot be recalled. The present is with us to solace and cheer. The garden is full of charm. It is a season of flowers when Flora's garland is beautiful indeed.

The Daffodils are too numerous to do justice to here. Fine are they now, but many are yet to open before the Poet's *Narcissus* is in full beauty with its white perianth, and crown with crimson or saffron rim. The great *telamonius plenus* is not over as we write, and its great tasselled yellow blooms contrast well with the pale flowers of *pallidus præcox*, or look dark beside the exquisitely coloured trumpets of Henry Irving. Queen Bess was the first of the *medio-coronati* or chalice-cupped Daffodils to flower. Very beautiful, too, is this flower, although we prefer the many trumpet-shaped varieties which in the border wave to the winds, nod from the rockeries, or in the grass bow gracefully before the breeze. There has of late been some discussion of the question of sun or shade for Daffodils. It is greatly a question of gardens. In some the white-coloured varieties require shade, but here nearly all are planted where they receive a good share of sun in summer. This has been found an advantage, and has added greatly to the free-blooming of many delicate sorts. I am also of opinion that many Daffodils will thrive better in the grass or as rock-garden flowers than if planted in the borders. Where one grows many bulbous plants the task of annual lifting becomes a physical impossibility in view of other calls upon time and attention. If one can in any way avoid this frequent labour it is decided advantage. Planting in grass is very beneficial to some *Narcissi*, but it is not every one who can afford them this treatment. Those who cannot do so,

but can place these favourite flowers on well-drained rockwork, will often secure the desired result. The Rev. G. H. Engleheart, one of our best authorities, says in a contemporary of *N. pallidus præcox*:—"On some soils it will live for a few years if planted on turf, but I know no other way of keeping it alive." Although I have grown it in the border for the last ten years with success, this pretty Daffodil is finer on a sunny rockery where it has been for eight years without replanting.

A single bulb of a pretty pale-coloured variety, once sold by Messrs. Barr & Sons as *pallidus præcox* Blond d'Or, has been on the same rockery in full sun for the same number of years, and has increased into a nice little clump, flowering freely every year. With such varieties as *coronatus*, *Colleen Bawn*, and other white trumpets

FIG. 67.—SECHIUM EDULE.

growing in full sun is found to be the best here, and we mean to experiment still further in the direction of trying delicate Daffodils on sunny rockeries where they are carpeted over with other plants.

The various members of the *Primulaceæ* now in bloom add much to the garden's interest. Quaint and curious looking are the Jacks-in-the-Green—as the *Polyanthuses* are called—whose bracts are abnormally developed into leaf-like ruffs round the flower itself. In various colours and shades they brighten up the borders or the slopes or paths of the rock garden. Beautiful, also, are the other *Polyanthuses* and *Primroses*, whose bright hues and neat blooms show how attractive flowers of this family are. Less showy, but no less attractive in their own way, are the plants which for convenience sake we call the species. Only a few are as yet in bloom, among these being several varieties of *Primula marginata*. A beautiful little flower indeed is *P. viscosa nivalis*, quite as well known under the latter name alone without the specific one of *viscosa*. There are several varieties of *P. viscosa*, which has two or three synonyms, but none is prettier than this little white-flowered variety. The species was named by Villars, and the plants are found in the Pyrenees and the mountains of Central Europe. It belongs to the group *Auriculastra* and the section

Erythrodosa of the Synopsis of the European species prepared by Mr. J. G. Baker. The small white flowers are freely produced in umbels on viscid scapes; the rather small obovate leaves are dark green, with closely set teeth, and are ciliated and viscid, or clammy, on both sides. This Snowy Primrose is said to succeed well in light soil in any position on the rockery in which it obtains plenty of moisture. In this garden it does best on a partially shaded rockery where it receives a little of the morning and early forenoon sun. It is given an adequate supply of water in dry weather.

The *Aubrietias* are great favourites of mine. They succeed well here, and when fully in bloom the effect they produce is very fine. They flower profusely and seed freely, with the result that self-sown seedlings become very numerous, and these show great variation in shade of colouring, ranging from very pale lilac to almost purple or crimson purple. A named variety new to me, which was bought last year under the name of *A. grandiflora Wallacei*, has been among the earliest to cover itself with flower, although some others showed a few stray blooms. The flowers of this variety are not so large as those of some others, but are of a bright crimson purple, which makes a fair sized plant very effective hanging over the ledge of a stone in the rock garden. We cannot but admire these early flowers, which please everyone by their appearance ere winter has fairly gone. They are a foretaste of milder days, when the garden glows with colour and the delight of the lover of flowers is at its zenith.—S. ARNOTT.

CHEMISTRY IN THE GARDEN.

(Continued from page 247.)

WE have seen that a mechanical analysis of a soil is a simple but effective means of determining the quantity of stones, sand, clay, and organic matter contained in it. Practical gardeners can as a rule distinguish a good soil from a bad one by its appearance, but to those not satisfied with empirical knowledge the question naturally arises, "What constitutes a good soil?" In trying to determine really what a good soil is many things, widely differing from each other, must be taken into consideration, the most important being those ingredients which constitute the food of plants.

What are the constituents of plant food, and how are they determined? To answer these questions we must ask the assistance of the chemist, who in his laboratory can by analysis tell us the names of the substances which are found in soils, and also those which are elaborated and built up into the plant body. After careful research chemists have told us that thirteen chemical substances are found in all plants, and by experiments it has been found that, with two exceptions, all these are essential to plants if they are to live and develop. The names of the thirteen chemical substances are as follows: Carbon, hydrogen, oxygen, nitrogen, sulphuric acid, phosphoric acid, potash, lime, magnesia, iron, chlorine, silica, and soda. The two exceptions named above are silica and soda.

All the carbon and part of the oxygen found in plants has been obtained from the carbonic acid gas which is in the atmosphere, the remaining oxygen and the greater part of the hydrogen being derived from water. Given a good supply of air and water plants under favourable conditions have an unlimited supply of carbon, hydrogen, and oxygen. Soils to be of any value to plants as food must contain a supply of potash, lime, magnesia, phosphoric acid, sulphuric acid, iron, chlorine, and nitrogen. Do they? It will be a great help to us in answering this question if we examine the chemical analyses of a clayey soil, a loam, and a sandy soil; for then we shall not only be able to see if they contain the necessary constituents of plant food, but also the amount of it which each contains.

ANALYSES OF SOILS.

Constituents.	Clayey.	Loam.	Sandy.
Potash	0.83	0.36	0.11
Soda	0.09	0.05	0.07
Lime	1.16	0.83	0.19
Magnesia	0.67	0.47	0.13
Phosphoric acid	0.18	0.12	0.09
Sulphuric acid	0.12	0.05	0.02
Iron oxide	5.93	4.67	2.61
Chlorine	0.05	trace	trace
Alumina	5.65	3.16	0.86
Insoluble silicates and sand	78.44	84.18	92.35
Organic matter	6.73	5.93	3.04
Containing nitrogen	0.15	0.18	0.13
	100.00	100.00	99.60

The above analyses show us at a glance that all those ingredients which are needed by crops for their growth and development

are present in all three soils. By looking at the above analyses it will be seen that the greater part of the soil consists of insoluble silicates and sand, substances which are of no value to plants as food; but in our consideration of a fertile soil we must remember that the mechanical condition is quite as essential for the perfect development of crops as the chemical, and although the amount of actual plant food appears small it amounts to something considerable if calculated per acre. The top 9 inches of soil on an acre of land would weigh about 3,000,000 lbs. If 100 lbs. of a clay soil contain 0.83 lbs. of potash, 0.18 of phosphoric acid, and 0.15 of nitrogen, 3,000,000 lbs. would contain 24,900 lbs. of potash, equal to 200,000 lbs. of kainit, 5400 lbs. of phosphoric acid, equal to 45,000 lbs. of superphosphate of lime, and 4500 of nitrogen, which is equal to 30,000 lbs. of nitrate of soda.

We must not suppose, however, that the vast amount of plant food in an acre of land, as shown by an analysis, is in a form suitable to the wants of plants, for only a very small portion of the soil substances are of any direct value to crops as food. The soil is a substance of a very complex nature. The plant food in it is present in a variety of forms, some of which are soluble in the soil water, or may be dissolved by the acid sap which is exuded from the tips of growing roots; while others are insoluble in the soil water, and the acid sap cannot dissolve them. The plant food which is present in a form soluble in water, or which may be dissolved by the roots of plants, is called the *active* part of the soil, while the insoluble form is known as the *dormant*.

Agricultural chemists do not attach so much importance to the analysis of soil as they did formerly, but are now investigating the active part of soils, or that portion which may be dissolved in water or weak acids. The analysis of the active portion of soils will no doubt prove of much greater value to cultivators than a complete analysis of a soil, for while the latter method may show them how much plant food a soil contains, the former will tell them whether it is present in a form suitable to the requirements of our crops.

Before leaving the composition of soils it will be advisable, perhaps, to give as far as our knowledge goes a brief description of the form in which plant food is found in the soil.

Nitrogen is present in soils chiefly as organic nitrogen, which is of very little or no direct value to plants. There are also smaller quantities of ammonium salts and nitrates present, and it is from the last named that plants obtain their chief supply of nitrogen.

Potash is found in soils principally in the form of silicate of potash, and silicates of alumina and potash. It is also found in very small quantities as nitrate and sulphate, both soluble salts, and it is chiefly from these two sources that plants obtain their potash.

Phosphoric acid is found in soils in chemical combination with iron, alumina, or lime. All these forms are insoluble in water, consequently are of no direct value to plants. The acid sap of the roots of plants, and the carbonic acid in the soil water, will convert the insoluble phosphate of lime into such a condition that plants can absorb it.

Lime exists in soils principally as carbonate of lime, and also to a lesser extent as silicate, nitrate, phosphate, and sulphate. Plants absorb nearly the whole of the lime they need from one or the other of the three last-named substances. Magnesia is present in soils principally in the form of silicate and carbonate of magnesia. It is also found in very small quantities as sulphate and chloride, and these are the sources from which plants obtain their chief supply of this substance. Sulphuric acid is always found in soils in combination with iron, lime, potash, or magnesia; and plants may absorb their sulphur from either of these compounds.

Iron exists principally in the forms of iron oxides or hydrates; there are, however, nearly always small quantities of sulphate and carbonate present, and plants may obtain their iron from either of the two latter-named sources. Soda is found in soils either as silicate or chloride of soda (common salt). Chlorine is present in most soils, only in very small quantities. It is generally found in chemical combination with soda, forming chloride of soda, and it is from this source that plants obtain their chief supply of soda and chlorine.—W. DYKE.

(To be continued.)

HIGHGATE WOOD.—We learn that the Committee appointed to secure the Churchyard Bottom Wood at Highgate for the use of the public has been taking active measures for that purpose. About £15,000 remains to be raised to cover the purchase of the ground, and circulars have been issued to the public giving particulars of the project and appealing for aid. Highgate Wood, in the opinion of the Chairman of the Committee, is "one of the choicest and most sylvan pieces of woodland which is to be found anywhere within the five mile radius of Charing Cross." Mr. Lionel Curtis, 1 Great College Street, Westminster, is the Secretary of the Fund.

DUBLIN-BY-THE-SEA.

A LITTLE business on a wild March morning left a narrow margin of time for those pleasures dear to the gardener's heart—viz., a look in on a kindred spirit, a walk over comparatively new ground, and a talk over decidedly old subjects, yet ever new and fresh, with a little to say of what was seen. Visitors to Dublin—some of them, at least—have left us under the vague charge of being rather slow—"a little behind the times, you know." We know, at any rate, that the charge is somewhat vague, for one with whom I endeavoured to join issue upon that point clinched the only visible nail in the argument by triumphantly trailing his timepiece, testifying to the fact indisputable of our being twenty-five minutes behind the time. We grant it; but for other matters. Whew! not so fast, my friend; that was in pre-electric days of Dublin trams. What would you think of us now? Now that we have hitched the lightning on to our brand new, long-bodied, comfortably cushioned, neatly trimmed trams swiftly running to and fro as far as Dalkey-by-the Sea; and, be it known to those of frugal mind, for fourpence all the way.

From "The Pillar"—the pillar of the greatest salt, who really looks very small so far up on that splendid Corinthian column near the G.P.O.—a penny tram of the ante-electric type takes one to the Haddington Road, where the overhead wires and a waiting motor-car with its rakish-looking mast invite us to mount the upper deck to see all that we can see of Dublin-by-the-Sea. All aboard. The motor man, with a handle in each hand and one foot planted on as bell-push, pulls and prods simultaneously, and the triple movement sets us gliding off and away. Surely 'tis the poetry of motion! On by an impenetrable evergreen screen stretched along the face of old Trinity's Botanic Gardens, truly tantalising to prying eyes; but amongst the dense leafage of Evergreen Oaks and luxuriant Hollies, the latter still having quite a Christmasy tint with a profusion of berries, we note two fine specimens of the yellow fruited variety, which are charming. Wonder what "F. W. B." is doing? Oh, we know, for it is the time when Daffadowndillies do blow, and our mental X rays detect him pacing the long border, revelling in a wealth of high colours, bicolors, maximuses, and others of that ilk.

On—on the smooth tram track, no shaking our bones over the stones of this, the rocky road to Dublin, till the grand panorama of "Sweet Dublin Bay" breaks into view. Opposite is the low-lying shore of Clontarf, which the Danes found so handy for beaching their long-waisted, high-prowed craft, and where they were defeated in the great battle fought on Good Friday A.D. 1014; but "The waves that brought them o'er, still roll in the bay, and throw their spray, as they break along the shore." It is a glorious view this gusty morning. Half a gale last night has worked old Neptune up to a frolicsome pitch—pitch and toss for a large steamer seen beating up 'gainst wind and tide. Comforting thoughts from the top of a tram. We have passed through several suburban villages, hamlets, or what not, all bearing distinctive or historic names, but they are in touch with each other through to the parent city, after leaving which the *bona-fide* traveller feels rather at sea on the subject, for when one thinks they are in Booterstown Mr. Cityman at our elbow says it is Blackrock, and the later suddenly resolves itself into Kingstown, which there is no mistaking, with its boldly projecting harbour visible for a long distance, and up to this point we may relevantly call all Dublin-by-the-Sea.

Booterstown must be particularised, for here spare time permits of a call at St. Helens, Lord Gough's charming marine residence, a somewhat plain unpretentious mansion, terraced on the sea front with a bijou Italian garden. This is, indeed, the feature of St. Helens, and perfect from all points of view. Between it and the sea there is a stretch of greensward to the boundary wall, over which that polar erection on the electric motor cars is seen gliding past, while the Dublin, Wicklow, and Wexford Railway runs immediately beyond and parallel with the highway. Yet these tracts of civilisation are but little in evidence, and from the terrace garden looking down, and over the third of a mile between us and the briny, all is absorbed in the satisfying seascape. This snug little demense of 120 acres is well timbered and undulating in character. A noble Beech near the north front of the mansion girths I do not know how many feet, but its waist is only in proportion to its far-reaching, well-balanced head, for it is one of those picturesque specimens which delighteth not the timber merchant's eye.

Among the many fine trees which adorn the demesne is a remarkable Evergreen Oak; it is, in fact, a giant of the tribe, and I am told that the late John Lamont of Edinburgh accorded to it as liberal a meed of praise from his more extended arboreal experience. The position of St. Helens is particularly favourable to the well-being of many so-called hardy trees and shrubs, which

so often planted in hope are scotched if not killed by abnormal severity further inland. Mr. Cumming, the head gardener, and manager of all he surveys to boot, has advantageously introduced some nice Coniferae about the grounds. Amongst flowering shrubs a group of *Staphylea colchica* has made vigorous growth. Our guide is great at Carnations, and holds a special trophy for good and all, having won it out last year in Dublin. As a "Mummer" he has done his duty in the years that have fled, but it is not a good time to be talking of Chrysanthemums now, and here in the very stronghold of Irish "Mum" growers it may not be expedient, but the glory of the garden this day is a house of Cinerarias, all the colours of the rainbow, and more besides, if there are any. These are shapely plants bearing huge blooms of surpassing beauty.

With the exception of a fine and well-placed conservatory attached to the east wing of the mansion the houses are small but useful, compact, clean, and all is done decently and in order. The garden, too, is comparatively small and of quaint formation, yet one feels in looking at the old brick walls that it is one with a history, probably contemporaneous with the adjoining demesne of Lord Pembroke, Mount Merrion, which good Queen Bess honoured with a visit. Well cared Pear trees cover the walls, promising well so far as bloom is concerned, and a small but choice collection of hardy plants adorn the borders. *Myrsiphyllum reticulatum* is a pretty evergreen climber, hardy here, and appreciated for furnishing long sprays of its elegantly marbled foliage for decorating. A batch of *Spiraea astilboides* in pots endorses the opinion previously formed that this is a charming plant thus grown, its slightly bronzed characteristic foliage being not the least of its attractions.

Souvenirs of the illustrious Field Marshal Viscount Gough are to be seen as we ramble round, and one can well understand how, after his long distinguished career initiated under Wellington at Talavera, and concluding with decisive victories gained during the Sikh rebellion, he loved to rest here upon his laurels when not spending his leisure at Loughcutra Castle, the family seat in the West of Ireland. Shortly St. Helens will change owners—pass into other hands—and Mr. Cumming will know it no more. Rather regretfully our gardening friend speaks of the attachment ten years has engrafted. It is a right and proper feeling, easy to understand, as we take a last look from the terrace ere leaving. Happily another door, and opening into a wider field, has presented itself, to which Mr. Cumming will shortly migrate, and which we trust will eventually afford to him the pleasant reflections this has done.

A short cut across the greensward previously mentioned brings us again to that triumph of modern locomotion—the electric tram. One is passing, and the motor man cuts off the current for a pick-up. Some two miles out at sea, immediately opposite, the waves curl over the battered hull of that wretched vessel the "Palme," which, driven in during a gale, left Kingstown, mourning for its gallant lifeboat's crew, at Christmas, fifteen months ago, and all but caused a lesser disaster on at least two occasions since. With a last look one wishes that the waves, "which roll in the bay as they rolled that day," would finish their work of destruction by removing the relics of that mournful episode in the history of Dublin-by-the-Sea.—K

EARLY CINERARIAS.

I WAS pleased to read Mr. Molyneux's remarks about Cinerarias (on page 276), but cannot agree with his idea that behind a north wall is the best place for growing the plants for the first four months of their growth. It is a vague idea of gardeners of the old school, but as a matter of fact such places are mostly cold and too dark, and I prefer to put the young plants in cold pits or frames facing the north, and shading them with light material during strong sunshine.

I have eighty plants of Cinerarias, including six *C. cruenta* and the same number of *C. multiflora*, which Mr. Lynch, Cambridge Botanic Gardens, kindly sent me. I sowed the seed the first week in July, and, what may interest some young gardeners, they have been grown from the seedling stage in soil that contained no fibre, and I shall be able to bloom my plants without any insecticide ever being near them. I have fourteen specimen plants mostly in 9-inch pots, grown without stopping, that, when in full bloom, which will be in a fortnight's time, will measure 2 feet 6 inches across the head, with leaves more than a foot in width.

It has often been said the Cineraria is an easy plant to grow, but young gardeners should not make too sure of this, or they may find that even the Cineraria will not look so well as it should do. I once heard a Welsh gardener tell his employer that any labourer can grow a Chrysanthemum, and so I think they could grow a Cineraria in some sort of way, but it would certainly be a very poor way.—THOMAS WEAGER.

REMINISCENCES AND REFLECTIONS.

MR. GEORGE LEE, in his interesting letter on page 291, last week, brings to light a circumstance that could have been known to few—namely, of Dr. Hogg giving £90 for a Tulip bulb. It may be assumed that this cannot be said of any person now living. The highest priced rectified Tulip in Messrs. Barr & Sons' list is Goldfinder (bizarre), 21s., and there is only one breeder equally priced (Sam Barlow), while selections of florists' Tulips can be had at "any price you like," between 7s. 6d. and 30s. a dozen. Thus does the old order of things pass away, giving place to the new.

Mr. Lee, in the last paragraph of his letter, makes mention of a former Duke of Bedford and Dr. Hogg, and may be interested to know that the Doctor became acquainted with the "botanist Duke," and visited him at Woburn. It may be said also that he had a great desire to accept invitations to visit Woburn again, to see the extensive new fruit farm, which is maintained by the present Duke for the purpose of public instruction, and where elaborate experiments on scientific lines—devised by the Director, Mr. Spencer Pickering, F.R.S.—are carried out by one of the Doctor's pupils, Mr. Lewis Castle. Although everything that kindly thought could suggest would have been done to relieve the veteran of fatigue, he never felt equal to the undertaking, and was in fact dissuaded from the venture by his medical attendant.

The letter of the octogenarian (Mr. Lee), it may be noted, reveals a mistake that appeared in the biographical notes on page 232, March 18th, and which has also been pointed out by Mr. H. Balderson—namely, that the Doctor was a spectator of Her Majesty's coronation in 1837. It has become rather common to regard that as the year of coronation; it was the year of the Queen's accession, the coronation following in 1838.

It is also somewhat doubtful if the Doctor's journey from Scotland in 1836 was by coach, as was stated. It is thought by some that he came by sea on that occasion, and by coach subsequently (as he well might). His sea voyage occupied five days—the time of an "American run" now. His craft was a sailing boat. There was not the same distinction in those days between passengers and cargo as exists now. The "boat" was no watertight, and it was little short of a miracle that it was not submerged in "Boston Deep." We should be surprised if during the time of danger there were a cooler person on board than the then young passenger whose life's voyage is ended. Dr. Hogg was seldom visibly alarmed, and never wildly excited over anything; but though calm in demeanour was persistent in any object he desired to attain, and his painstaking in the question of synonyms, mentioned by Mr. Lee, will be fully understood by those who enjoyed his acquaintance, while over the "skeletonising" of the snake he would begrudge no time in having a "perfect" specimen.

His innate patience and perseverance was displayed in a striking manner in a very common occupation—the opening of string-tied parcels. The writer has observed him open hundreds (containing fruit) but never saw him cut a string. "Let me cut it, Doctor," was more than once requested when he was struggling with a knot. "No thank you," he would reply; "knots were made to be untied, and I am not often beaten with them." But though he would expect no one to aid in opening the boxes he was always ready to be assisted in naming their contents. His zest, however, for naming fruit gradually waned, and eventually he abandoned what had evidently become an irksome task, in part no doubt through the consciousness of failing memory.

In journalism it may be said of the Doctor and his distinguished co-partner, Mr. Johnson, that they belonged to the "old school." Such a thing as making a rush to be first with a report appeared with them to be an unknown quantity, though they appreciated activity in others. An incident in reporting afforded evidence of this. Several years ago the Doctor was at a great show in Edinburgh, where he also had a staff reporter. The judging commenced at six o'clock in the morning (Wednesday). The reporter followed the judges closely, and with nimble fingers jotted down the awards and his impressions. Two hours later the Doctor found him busy as the proverbial bee. "Ah! Mr. Scribe, a great show this, plenty for us both. What part shall I do?" He received a reply that for the moment staggered him. "I think you had better go to the post office, sir, and secure a wire!" For a moment he stood mute, then replied, "Did you say go—to the—post office, and secure—a what?" "Yes, secure a wire for half-past nine; it will not be my fault if a report of the show is not in to-morrow's Journal." "Oh! by George, do you mean it can be done?" "Done; yes, if you don't mind paying. I'm off to the hotel, and the report will be ready at 9.25." The reply came firmly enough this time. "Yes, I see it all now; and I'm off to the post office." Perhaps if ever the Doctor bustled it was then. It was a new mission. He was soon at the hotel, watching progress with a curious kind of anxiety. "There, it's done, Doctor, three minutes before time—it's always well to be a little before time, you know." "Yes, it is; I'm afraid I am getting behind it." Gathering his sheets to go, the scribe was stopped. "No, no. I will do the rest; you get your breakfast, and a good one; then take a week where you like, and charge all to the office." The report appeared as intended, the first of its kind, in the *Journal of Horticulture*.

Returning after his "week," and entering Mr. Johnson's room, the grand old man (for such he was) rose from his chair, and after a hearty

handshake with a "Glad to see you here again," went on in his firm, sonorous voice, "All I have to say is, I've carried this for fifty years and never earned it; you have; take it, and good luck to you," as he handed over his gold pencil. There was no mention of the report, nor was there a few days later when the Doctor wrote the monthly cheque with the remark, "It will be like that" (with a slight emphasis on the "that"). "in the future, and I hope we shall work together for many years." Such is the kind of appreciation that encourages, and in return no man worthy of the name would fail to give his best and devoted services.

What changes have occurred since that Edinburgh Show, and what lessons they teach of the uncertainties of and in life. Two great Editors gone, four printers' overseers, and many a bright penman whose loss is deeply mourned. Yet at least a quartet of old literary workers remain, examples of prudent lives, with the resultant still bright intellects and keen perceptions—namely, "D., Deal," and Messrs. Fenn, Abbey, and Pownall. These are the "Journal's" representatives of rich ripe autumn. Such veterans like to look back on the past, and reflect on their summers of vigorous manhood and springs of joy and hope; and they also like to see the summerhood of others displayed in full strength, as well as the springtide of probationers, like fresh young buds, represented in these pages.

These young men should know, and never forget, that if they wish to advance in life they must do so by intellectual culture, with the best of work, in sight and out of it, that is attainable by diligent practice, honest, honourable labour, unswerving loyalty, and patient endurance. They must work to win, not trusting for one moment to others to push them on, for pushing, as they will find on reflection and many examples, is usually followed by stumbling and a fall. Let a man, be he a gardener or anything else, attain by his own efforts competency, with prudence and a controlling capacity above his fellows, and his services will be sought for. There never was a time when men of the greatest skill, combined with tact and high conduct in their respective callings, were in such demand as now; not themselves, but others being the judges. As all know, accidents and misfortunes may befall the most able and worthy, but the duty still remains that each should strive by all the means available to excel his fellows in all that goes to build up the genuine man—to be respected, and the most accomplished gardener. These are the men who more than all others stand to win in the battle of life.—THE SCRIBE.

VIOLETS IN FRAMES.

Now that the time is at hand for commencing operations to insure the successful cultivation of this the sweetest of winter and spring-flowering plants the subject is worth consideration, as the pits and frames are now being cleared for other purposes, and frame cultivation of Violets is at an end for this season. But we must begin our task again if we wish to have a healthy stock of plants and abundance of large sweet-scented flowers during next winter.

The system we pursue is planting single crowns so as to cover the entire surface of the bed, and we are so satisfied with the results as to totally discard the clump system, except for pots. Our mode of procedure is to plant small side shoots or sets 6 inches apart in a nursery bed, and when they have made good strong crowns they are planted out about the middle of May in a rich prepared border 15 inches apart. During the summer they require looking over once a fortnight to remove suckers and surplus runners, leaving four or five of the strongest to each centre crown, and when they have formed a knot to stop it. The result will be the nourishment will form a good plump crown, instead of expending itself in useless suckers and runners. Small pegs should be used to fasten them down, to prevent the wind blowing them about until they have taken root.

Towards the end of September the pits or frames must be prepared. They should have a south aspect, and if there are pits that can be spared adjoining a house heated with hot water so much the better, as small perforated air bricks can be let into the dividing wall, and in frosty weather the advantage will be great, as ventilation can be afforded without admitting the cold air. The bottom of the pit can be covered with a layer of brushwood and leaves made firm, on the top of which place about 12-inch depth of good loam to within 6 inches of the glass. The plants can then be carefully lifted and placed out, pegging the radiating crowns so as to cover the entire surface of the bed, as there is no fear of the foliage overcrowding, each crown having only its proper supply of leaves, all useless wires being removed as soon as they appear.

Where there are no pits to spare such as I have described we must have recourse to the common wooden frame, which, when elevated on a layer of faggots, filled with loam, and planted like the others, a lining of fermenting material can be applied to the base, and the heat will rise into the frame, which of course must be well ventilated. I prefer a rather strong loam as in this the plants produce flowers of a rich deep colour, whereas the absence of moisture in a sandy soil causes the plants to become infested with red spider, which soon destroys the foliage and greatly weakens the constitution of the plants. If possible sets for planting should be procured from plants that have been liberally treated the previous year, for, like the Strawberry, they are apt to degenerate rapidly if left to themselves.

The foregoing remarks may be of use to those who have to produce a large supply of this favourite flower during the depth of winter, and to those who have not tried single crowns I would advise a fair trial

during the coming season; and if properly carried out they will not revert again to the clump and row mode of planting, as they will find that in the same space finer flowers and larger quantity can be grown on the "single crown system."—GROWER.

THE INTRODUCTION OF VEGETABLES.

HUME, the historian, tells us that it was not till the middle of the sixteenth century, during the reign of Henry VIII., that any salads, Carrots, Turnips, or other edible roots were grown in England. The small quantities of these vegetables that were previously used were imported from Holland and Flanders. Queen Catherine, when she wanted a salad, was obliged to dispatch a messenger abroad on purpose to procure it. Although the Potato was imported into Spain early in the sixteenth century, and travelled thence to Italy, it did not arrive in England until 1586, on the return of Sir Walter Raleigh from Virginia, who is believed to have been the first to have brought it here. Sir Walter did our fellow countrymen the Irish a good turn, for he personally distributed a large number of tubers throughout that country, and it was not until after his death that they found their way to London from Dublin. It is a noteworthy circumstance that Linnæus conceived a violent prejudice against the Potato; in fact, he preferred the Jerusalem Artichoke, alleging that the former belonged to a poisonous genus, the Solanum, and was injurious. We all know now that it is very wholesome when well boiled, and quite indispensable in the household.

Peas, perhaps, take the palm as being the most delicate and agreeable of vegetables, wonderful improvement having taken place in their development and flavour, more especially in recent years, brought about by the skill of our leading seedsmen. They are even to be had fresh in the markets during nearly half the year. Attempts have long been made to preserve Peas for winter use, and this has been effected with a certain measure of success, but we agree in the main with Appert, a horticultural writer of a hundred years ago, who wrote that "They looked pretty enough, but flavour they had none at all." They are much used throughout the winter in this state in the hotels and restaurants. In Queen Elizabeth's time they were also imported from Holland, which made Fuller say sarcastically that they were "Fit dainties for ladies—they came so far and cost so dear."

Beans are the first vegetable that became popular and generally used, being largely eaten by the ancients. Pythagoras, the old Greek philosopher, enjoined his followers to abstain from Beans, because it is thought he intended to restrain them from meddling in politics, for it is well known that votes were formerly given by Beans, placing them in urns, the forerunner of our present system of voting by ballot. Haricot Beans, boiled and eaten with oil and vinegar, are generally used by the French daily, forming a portion of the ordinary diet. They are wholesome and nutritious, but are not in such favour with us.

Artichokes (*Cynara scolymus*) are a pleasant vegetable, by no means generally eaten. Of old the juice enjoyed a reputation as being a cure for rheumatism; this virtue, however, is not, so far as we know, claimed for it at the present day. Jerusalem Artichokes owe their name to two odd reasons. They are the tubers of *Helianthus tuberosus*, a species of Sunflower. Jerusalem is a corruption of *Girasole*, its name in Italy. Artichoke is due to its strong resemblance in taste to the real Artichoke. Salads are very popular, but are not highly digestible. A distinction, however, exists, Cucumbers being considered the most indigestible, and Lettuce the most digestible. Lettuce, it would seem, owes its innocence to its containing a small quantity of narcotic matter. Nothing, perhaps, more shows the popularity of salads than that an eminent man like Evelyn, of diary fame, should have written a book on them. He enumerates seventy-two herbs fit to enter into their composition in his "Acetaria: a Discourse of Sallets," published in 1699.—WM. NORMAN BROWN.

NOTES ON DAHLIAS.

COMPARATIVELY few flowers enjoy so wide a popularity as the Dahlia, and the reasons are obvious. In the first place it is essentially an accommodating plant, and is perfectly at home in the gardens of all sorts and conditions of men. Perhaps, excluding the queenly Rose, no flower finds such favour with the working thousands to whom floriculture is a useful and elevating hobby. To such men the merits of the blooms grown in tiny gardens and allotments form the subject of many an animated conversation in the depths of the mine, by the forge, and amid the never-ceasing rattle of the spinning frame. Yes, to appreciate fully the value placed upon the Dahlia one must be in close touch with this important section of the population. Then we have the enthusiastic experts who display their flowers and crowd round the tables at the Crystal Palace, Royal Aquarium, and other important shows. To them Dahlia growing and raising is a fine art, and one, too, wrought with interest—yet another testimony of the sway which the flower holds. Indeed, one might go on at length enumerating different types of horticulturalists to whom the cultivation of the popular flower is a pet theme.

I said the plant was accommodating, and so it is in more ways than one. Where is there another in which we get so charming a variety, such a disparity in type? Look at the large show kinds—perhaps not favourites with everyone, but containing such a substance of bloom, such a regularity of outline, and depth of colour! Then the "fancy" kinds, with their lesser forms and strange mixture of tints! They, too, have their admirers, and during recent years have come rapidly to the

front. Perhaps, however, for popularity the palm must be given to the Cactus, as its pleasing form and striking colours, coupled with its usefulness for decorative purposes, has placed it in the forefront of this extensive family. More simple, more unobtrusive, and with a shyness that courts not publicity, are the words that perhaps best describe the Pompons; yet they have a beauty quite distinct, and peculiarly their own. Last, but by no means least, there are the singles, though in this section opinions divide, and the beauty of single Dahlias does not appeal to some who admire the double and more substantial forms. To be seen at their best they should be planted *en masse* in a garden where they are in character with the natural surroundings. Those who have seen the large masses of single white Dahlias contrasting with the bright scarlet beds of *Formosa* (one of the most floriferous varieties) as grown in the naturally formed gardens at Alton Towers will, I think, agree with me that as a beautifier of the flower garden we have few superiors to the single Dahlia.

Ever looking ahead, thoughts are already centred on the furnishing of the flower beds, and propagation is in full swing. Many a grower, both large and small, has examined with anxiety his store of tubers during the past few weeks. Let us hope that in all cases they have been found sound and in good condition, for on careful storing depends the success of the following season. To be dry and frost-proof are the two indispensables, and these provided no fears need be entertained. Shrivelled tubers when taken out of their winter quarters denote too high a temperature, and too much moisture causes wholesale decay. A dry disused cellar where frost could not penetrate was the best place I ever had for storing Dahlia tubers, and there, too, *Gladiolus* corms were habitually wintered without a single loss. Care should always be taken that each variety is carefully labelled and kept separate, otherwise confusion is sure to follow. Some varieties, it is true, can be detected by the foliage, but in others it is so similar that this is impossible, and what looks worse than when planting a bed of one kind to find at flowering time that there are several others mixed with it?

Old tubers for providing cuttings are placed closely together on a slight hotbed with a little leaf mould sprinkled over them. Soon they push an abundance of stout shoots, and these taken off when about 3 inches long with a heel of the old tuber attached root rapidly. The most expeditious way of raising large quantities of good strong plants is to root them in a bed over gentle heat, and then transfer to 4 or 5-inch pots. If grown in the cool and close to the light, being gradually hardened before standing outside, the plants will be in fine condition at bedding time. Spring-rooted Dahlia plants are often grown in thumb pots, particularly where lack of space is a consideration. Arguments may be urged against the method, for long before the plants can be removed to the open ground the pots are one mass of roots, and the growth in consequence is matured and stunted. Several weeks elapse after planting before root action recommences, and those weeks are practically lost—hence the advisability of growing the plants without a check.

But what about soil? perhaps some novice is impatiently muttering. Well, the Dahlia loves a fertile medium, but an over-liberal supply of strong manure is a mistake, or the growth is so rank and robust, the consequence being that few flowers are produced. A little guano or night soil may be used, instead of rich farmyard manure, with good results. Some varieties, however, grow much stronger than others, therefore it is difficult to lay down any hard and fast rules on this point, and judgment must be used by the cultivator. One of the blocks over which many Dahlia growers stumble is that of planting them too closely together. The result is a thicket of growth, and the real beauty of the plants is almost undiscernible. It is better to err on the other side when placing out the plants. Neat stakes, sawn out and painted, are perhaps the best to use for supporting the plants, though thick bamboo canes are also largely used. Once I remember a young Larch plantation caught fire during the dry days of spring; the charred poles about 4 feet high, left standing after the conflagration, formed a stock of Dahlia stakes which lasted for years, the charred bark seeming to be a means of preservation.

Dahlia growers have many enemies, and where rabbits abound none more deadly than these. When the plants are young and the leaves tender the furry creatures have a decided liking for them, and unless adequately fenced out will devour the foliage and stems wholesale. Later on there are earwigs, for the capture of which there is no better plan than the old-fashioned one of fixing inverted flower pots on stakes, looking them over continually, and destroying the troublesome pests.

I do not propose wearying the reader with long lists of names, as a selection of the best varieties and most recent introductions may be obtained from the perusal of any florist's catalogue. One word, however, may be said; do not be misled by appearances, particularly with the Cactus sorts. Many of them look beautiful on the exhibition table, but in the garden their flowers are produced on such short footstalks that they are completely hidden by the foliage, and the ardent amateur, after paying a good price for the plants, is disappointed. Moral—Learn something of the habit of the plant before purchasing. Single Dahlias are often raised from seeds, but it is better to get a collection of such distinct kinds as *Formosa*, *Negresse*, *Duchess of Westminster*, *Miss Roberts*, and *Paragon* and propagate year by year.

Something, too, might be added about exhibiting, treatment of the tubers after frost has asserted its power, and many other operations, but these can be left till later. The year is yet young, and it is only propagating time, but to those enthusiastic in the culture of the ever-popular Dahlia the foregoing reminders may prove useful.—G. H. II.

"JOURNAL OF HORTICULTURE" EDITORIAL DEPARTMENT.—

From the present date, and until further notice, it is particularly requested that all letters and parcels intended for the Editor, also all communications for insertion in the *Journal of Horticulture*, be addressed to 8, Rose Hill Road, Wandsworth, London, S.W. N.B.—Business letters and advertisements must be addressed to the City Office.

— WEATHER IN LONDON.—While we have had several varieties of weather during the past week, there is nothing equal to that of the "Westminster Gazette" paragraph which will be found below. Sunday was a glorious day, warm and bright; Monday was overcast, with occasional showers; while Tuesday was practically the same, with the addition of a few gleams of sunshine. On Wednesday it was wet in the early morning, but fine later.

— WEATHER IN THE NORTH.—A change for the better has taken place in the weather of the past week. On only one morning was there frost, and with westerly winds and occasional showers there has been more of the feeling of spring. Tuesday morning was showery, with S.E. wind, and thermometer at 46°.—B. D., *S. Perthshire*.

— JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY.—The latest issue of this publication has just come to hand, and contains much sound matter of value to horticulturists. Particularly interesting are the essays on New Roses, by Rev. J. H. Pemberton; Fern Generation, by Mr. C. T. Drury; Forcing Lily of the Valley, by Mr. T. Jan-
noch; Gladioli, by Mr. J. Barrell; Hardy Summer Flowers, by Mr. E. Burrell; Chrysanthemums, by Mr. W. H. Lees; Seed Growing, by Mr. R. Fife; and Floral Decorations, by the Rev. G. Henslow, M.A.

— WOLVERHAMPTON AND DISTRICT HORTICULTURAL CLUB.—Under the auspices of this flourishing Society Mr. John Pope, F.R.H.S., King's Norton, was recently invited to deliver a lecture on the Narcissi, Mr. Simpson in the chair. The subject of the paper was divided into four parts—viz., "The probable future development of the bulb," "Its cultivation," "Its value as a forcing plant for decorative purposes," "Its value from a commercial grower's point of view." The essayist's remarks were listened to with the deepest interest. In the discussion which followed several questions were satisfactorily replied to by the essayist. The meeting was rendered further interesting by a display of several bunches of the old Noisette Rose Fortune's Yellow, which resembled by the gaslight miniature Pæonies, so beautiful were they. The grower, Mr. Bradley, gardener to Miss Perry, Wergs Park, stated that the plant was about ten years old, and is growing in a cool greenhouse; also that he had during the last few weeks cut hundreds of the blooms, whilst in the same house a large plant of Maréchal Niel does not flourish, though growing under similar conditions.

— WAKEFIELD PAXTON SOCIETY.—The speaker at the meeting of the Paxton Society on Saturday evening, April 3rd, was Mr. R. T. Pitts, Stanley, who gave an essay entitled "Gardening in Relation to Amateurs." Mr. Tunnicliffe took the chair, and Mr. Brown of Outwood was Vice-Chairman. Addressing himself to his subject, Mr. Pitts said he desired to indicate how an amateur gardener might make the best use of his bit of ground, not, however, as a financial undertaking. First, the ground must be drained some 8 inches beneath the surface. Dig deep for cultivation in autumn, and put in the manure. Make a cordon fence of Gooseberry or other fruiting shrubs, which should be kept well cut. French Beans might be planted, but vegetables should not be too thick on the ground, and also Brussels Sprouts, Savoy, and Cauliflowers. An amateur should also have a cold frame if he wishes to get the best results. Broccoli should not be gone in for heavily, otherwise the weight of vegetables would be ready simultaneously. With only a small garden an amateur should not grow Potatoes, which could be bought very cheaply. Mustard and Cress might be sown often and cut quickly. Lettuce requires a little more time. Unsightly places might be covered with Rose bushes, Ivy, Artichokes, or a Virginia Creeper. Or a bank might be made and covered with hardy Ferns. Under no circumstances should a garden be crowded. The usual votes of thanks were accorded.

— GARDENING APPOINTMENT.—Mr. R. W. Smith, for the past seven years foreman at Raby Castle Gardens, co. Durham, has been appointed head gardener to W. Tunstill, Esq., Reedyford, Nelson, Lancashire.

— GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Mr. Arthur W. Sutton of Messrs. Sutton & Sons, Reading, has given a donation of £100 to the "Victorian Era Fund" which is being raised by this Institution to commemorate the Diamond Jubilee.

— GARDENERS' ROYAL BENEVOLENT INSTITUTION—Worcester and District Branch.—We are informed that by the kind permission of the Right Hon. Earl Beauchamp the beautiful Gardens, Maze, and Rockery at Madresfield Court will be open to the public on Thursday, April 22nd, 1897. Admission:—Two till five, 1s.; five till seven, 6d. The proceeds will be given to the above excellent Institution. The spring flowers, with which the Gardens abound, will be in perfection.

— MR. WILLIAM COOMBER.—We regret to learn that owing to the death of the late Lord Lilford, Mr. Coomber will shortly have to leave Lilford Hall, the present lord taking his own gardener there with him. This is very unfortunate for Mr. Coomber, who was a victim of the pecuniary misfortunes of the Royal Botanic Society. A worthy man and an excellent gardener, all who know Mr. Coomber will be glad to hear of his obtaining an appointment in private or public service.

— PRESENTATION TO MR. A. GRAHAM.—An interesting function took place at the Southampton Hotel, Surbiton Station, on Wednesday evening, when Mr. A. Graham, the late Superintendent of the Royal Park and Gardens, Hampton Court, was presented by a number of his friends with a pair of silver-plated entrée dishes and a purse of money, together with an illuminated address, on the occasion of his retirement from the important position he has held for a period extending over twenty years. Advantage was taken of the occasion to present to Mrs. Graham also a handsome gold watch, the gift of an anonymous donor.

— THE LATE MR. W. G. HEAD.—Very sorrowfully, but without surprise, did I read in this week's Journal of the death of Mr. Head. Having no personal acquaintance with him but as a co-judge—though not in his department—at Shrewsbury, I am not able to speak of him as others can; but last August, after the judging was over, and we sat together in the Secretaries' tent, he told me of his peculiar disease and what he suffered, of the proposed operation, and its risk and doubtfulness. He had a very quaint way of expressing himself, a quick perception of humour in either a speech or a situation, and a ready and witty repartee in a give-and-take conversational chat with brother gardeners. He had a forceful nature, which had enabled him to overcome immense difficulties under the latter-day's severely economical management of the Crystal Palace Company. He will be much missed.—N. H. P.

— SHROPSHIRE SPRING SHOW.—The annual spring show of the Shropshire Horticultural Society, which took place in the Music Hall, Shrewsbury, on the 7th inst., resulted in another of those grand successes which have marked the exhibitions of the Society of late years. Of the beauty of the display on these occasions much might be—indeed, has been—written; but no words, however eloquently expressed, could convey at all an adequate idea of the grandeur of the scene presented by the wealth of flowers and foliage which the Society is instrumental in bringing together; it must be seen to be properly appreciated, and when once this is done it is no mere exaggeration to say that it will not easily be forgotten. These remarks apply with singular appropriateness to Wednesday's show, which in many respects was in advance of any of its predecessors; while from another important point of view—that of attendance—there were not wanting evidences to prove that the exhibition is increasingly popular with the public. The arrangements for the event were admirably carried out by the Hon. Secretaries (Messrs. Adnitt and Naunton), and in order to avoid the crush which has been experienced in past years in the large hall, it was decided to utilise the front room of the building, wherein were staged some half dozen classes in the open section and the whole of the exhibits in the amateur department. This new departure worked most successfully, and the executive are to be congratulated on having brought it about. The display, as we have already said, was a first-class one from a competition point of view, but, as on previous occasions, the general effect was considerably heightened by the displays of the local florists and others. Lack of space precludes our giving a detailed report of the exhibition which so admirably upheld the status of the Society.

— **DAHLIA ANALYSIS.**—I regret to find that in the list of Cactus Dahlias, given on page 288, I have by an unfortunate oversight omitted that lovely variety, *Delicata*. It should stand third on the list, and follow *Lady Penzance*.—E. M., *Berkhamsted*.

— **"LA SEMAINE HORTICOLE."**—Such is the title of a gardening paper, published under the direction of Mons. Lucien Linden, at 11, Rue Belliard, Brussels, which has now reached its eleventh number. The journal is printed on slightly toned paper, with good legible type, while the illustrations are engraved on wood. The list of names comprises some of the best-known writers on horticultural subjects on the Continent, with Mr. James O'Brien from this side of the stream.

— **ASPARAGUS AND EARLY RADISHES.**—A correspondent informs us the Asparagus was cut in the Vale of Evesham on March 26th (the same day as by Mr. Orchard in the Isle of Wight), and the first Radishes drawn on the same date. Evesham is famous for early Radishes, among other crops, and it would be interesting if someone acquainted with the subject could describe the methods of growing and marketing, also indicate the value of the crops in that fertile and well cultivated district.

— **READING GARDENERS' ASSOCIATION.**—The closing meeting of the spring session of the Reading Gardeners' Association was held on Monday evening last, when Mr. C. B. Stevens presided over a large attendance of members. The paper for the evening was "Zonal Pelargoniums" by Mr. H. Shoesmith, Claremont Nursery, Woking. The paper was of an exceedingly practical character, being full of plain cultural notes, and was followed by the members with the closest attention. A hearty vote of thanks was accorded.

— **CARTERS' PRACTICAL GARDENER.**—We do not know how many editions of the popular work have been exhausted, as this does not seem to be stated in the last and the best, of which a copy is before us. Externally it is the most attractive of all, and internally the most useful, because, in addition to the varied and valuable matter in its 200 pages, there is the addendum of an excellent index. If in a multitude of councillors of experience is to be found wisdom, surely wisdom on useful and ornamental gardening is to be found here, and all, as before, for 1s. It is wonderfully cheap.

— **ROYAL METEOROLOGICAL SOCIETY.**—At the ordinary meeting of the Society, to be held at the Institution of Civil Engineers, Great George Street, Westminster, on Wednesday, the 21st inst., at 7.30 P.M., the following papers will be read:—"The Relation Between Cold Periods and Anticyclonic Conditions of Weather in England During Winter," by W. H. Dines, B.A., F.R.Met.Soc.; "Sunspot Influence on the Weather of Western Europe," by A. B. MacDowall, M.A., F.R.Met.Soc.; "The Use of Kites to Obtain Meteorological Records in the Upper Air at Blue Hill Observatory, Mass., U.S.A.," by A. Lawrence Rotch, B.Sc., F.R.Met.Soc.

— **SHIRLEY GARDENERS' ASSOCIATION.**—The first meeting of the fourth year of the above Society was held at the Parish Room, Shirley, Southampton, on Wednesday the 7th inst., the President, Mr. W. F. G. Spranger in the chair, there being a fair attendance of the members. The Society had been most fortunate in securing the services of the Rev. G. H. Engleheart, M.A., Appleshaw, Andover, who is a well known enthusiast in the culture of the Narcissi, and whose lecture on their cultivation was listened to with the utmost attention, and was much applauded. First he showed how the whole Daffodil family was divided into classes, the time for planting, the soil and preparation most suitable to their needs. He urged his audience to grow them from seed, speaking of the pleasure to be derived from watching the unfolding of the unknown flowers day by day, in the expectation of something new or interesting, and show how the classes had been made to merge one into the other by cross fertilisation and seed selection, resulting in some grand hybrid flowers, a few of which he exhibited at the meeting, and four of these were awarded extra special certificates. A brief discussion ensued, and the lecturer replied to several questions, one bearing on the fertilisation of the flowers artificially, drew forth a useful lesson on the subject. A hearty vote of thanks was accorded to the lecturer, and also for his grand collection of seedling flowers exhibited to illustrate the lecture. Mr. B. Ladhams sent about thirty varieties; Messrs. Barr and Sons, Long Ditton, sent thirty-five varieties of Narcissi; and there was also a good exhibit of hardy flowering shrubs and American plants sent by Mr. W. H. Rogers, Red Lodge Nursery, for which the exhibitors were accorded a hearty vote of thanks. A vote of thanks to the President concluded the meeting.

— **NEW ZEALAND SEEDS.**—We are informed by Messrs. W. G. Innes & Co. that Her Majesty has been graciously pleased to accept from Messrs Nimmo & Blair, of Dunedin, a collection of New Zealand native tree, shrub, and plant seeds.

— **SHEFFIELD BOTANIC GARDENS.**—It is said that a section of the public of Sheffield is determined to celebrate the Queen's record reign by purchasing the Botanic Gardens and handing them over to the City authorities for the use of the public. Towards this object half of the shares in the Gardens have been offered and £1500 subscribed. The Gardens have been conducted at a loss, and there has been a fear lest they should come into the hands of the speculative builder.

— **TORQUAY GARDENERS' ASSOCIATION.**—A few days ago the members of this excellent association held their annual general meeting to hear the reading of the report and the balance-sheet. Both of these were very satisfactory indeed, and show how admirably the Society is managed by the various officers. Mr. F. Smale, the indefatigable Hon. Secretary, was re-elected, and will, we are sure, give the same close, keen attention to the affairs of the Society in the future as he has done in the past. The summer excursion, held in July, will be to Kingsbridge. The Secretary's address is Isaline, Avenue Road, Torquay.

— **ANTI-BLIGHT.**—I see anti-blight is inquired about on page 283. I enclose you the two last recommendations I have received praiseworthy of its behaviour. You all left me so severely alone last year that you had no chance of witnessing its continued usefulness with me. One compensation, however, we had your notes from Scotland, but he of King Street never gave to me of his whereabouts. I learn he is again off to Sicily, or somewhere, and will not return till the end of the year.—ROBT. FENN. [The testimony of the two practical gardeners is conclusive. With an atmosphere favourable for Tomatoes, *plus* timely "dustings," we suspect the fungus cannot take possession of them.]

— **BIRMINGHAM GARDENERS' ASSOCIATION.**—The last meeting on the spring syllabus took place on Monday, April 12th, when Mr. Geo. Bunyard, the Royal Nurseries, Maidstone, with Mr. W. B. Latham in the chair, gave a most instructive and comprehensive verbal lecture, entitled "Common Mistakes in Fruit Culture," before an appreciative attendance of the members. As indicated by the title, Mr. Bunyard's remarks were confined principally to the too common mistakes made in the planting and pruning, as well as to the selection of unsuitable varieties of different kinds of fruit trees, rather than to a description of the proper way to treat fruit trees. In the discussion which followed a few questions were put by one of the members to the lecturer, and were satisfactorily answered. A hearty vote of thanks was accorded to Mr. Bunyard.

— **THE WEATHER LAST MONTH.**—March was changeable with much wind and rain throughout, and was remarkable for a very low reading of the barometer on the 3rd inst. The prevailing direction of the wind was W. on twenty-two days. Total rainfall, 2.41 inches, which fell on nineteen days. This is 0.85 inch above the average for the month. Barometer (corrected and reduced), highest reading 30.143 inches on the 8th at 9 A.M.; lowest, 28.575 inches at 9 A.M. on the 3rd. Thermometers.—Highest in the shade, 61° on the 21st; lowest, 25° on the 30th. Mean of daily maxima, 50.22°; mean of daily minima, 37.39°. Mean temperature of the month, 43.80°; lowest on the grass, 17° on the 30th; highest in the sun, 116° on the 21st. Mean of the earth at 3 feet, 42.16°. Total sunshine, 121 hours. There were five sunless days.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham*.

— **VARIETIES OF WEATHER.**—Many people allow Manchester to occupy the post of honour as regards bad weather, but the "Westminster Gazette" in the subjoined paragraph proves London to be an excellent second. After the experience of Wednesday the 7th inst., no one can resent the opinion once expressed by an American visitor that we have no climate in this country, but only samples. We certainly had a variety of samples exhibited to us. In the early morning it was a November fog. This was succeeded by January rain and early March wind, then a May sun suddenly burst out, but it had no sooner got inside the houses than it was drowned out by a burst of December hail and sleet. To cap it all, the thunder and lightning took the next turn with an August display of fireworks. And then the day finished up in November. These samples, in addition to their variety, visited the different parts of London in streaks, which added much to the interest, for it enabled one to start from one district in May, and arrive at another several months earlier. It is to be hoped that the weather will have exhausted itself before Jubilee week, and that there will be no storage of rain work left to be done during that festive period.

SOPHRONITIS GRANDIFLORA.

A CHARMING little Orchid when well grown; its large bright flowers give it a cheerful appearance, totally distinct from all others that are flowering at this season of the year. It will grow very well on small blocks of wood (fig. 68), but in this position requires more attention in watering than when grown in small shallow pans. It should be suspended from the roof, and if employed freely or alternately with *Odontoglossum Cervantesi* or even the beautiful and distinct *O. Rossi majus*, which also flowers about the same time, the effect is all that can be desired. The *Sophronitis* is an obliging Orchid, for it appears to thrive well either in a warm or a cool house, and I have seen some grand specimens in a stove with brighter flowers than when in a cool house. It delights in a little heat, such as afforded in an intermediate house, while making its growth, but when at rest should have cool house treatment, which insures a vigorous growth the following season. Although its flowers are brighter in heat they do not last quite so long as in a cooler house. To grow this Orchid successfully too much rooting material should not be given it; but the pans should be liberally drained with crocks and charcoal, a little peat fibre and living sphagnum being used for the compost.—GROWER.

THE PELARGONIUM.

IN the following notes I do not propose to deal with the beautiful and ever-popular Zonal, but with those plants that have rough, serrated leaves, which used to be very largely grown by cottagers for window adornment, and possibly are now in some parts of the country, and was commonly known as the Nettle Geranium. It is one of the most beautiful of our greenhouse plants, and a good collection when in full bloom cannot be excelled for brilliancy of display. There is a chasteness in the bushes, blotches, and markings that is always admired. Another recommendation is its hardiness, as it will live and flower in the open air in summer, and can be wintered almost anywhere if frost is excluded. In mild winters some of the strongest varieties would survive in a cold frame if carefully protected with mats. I should not, however, advise this course to be adopted; it would be too risky for valuable plants. It flourishes in a cool atmosphere and sickens in a hot one, while it is easy to propagate and easy to grow. Like everything else it has its enemies. Green fly is extremely partial to it, hence the difficulty of amateurs to keep it clean and free from blight. It is not impossible to grow healthy plants if you only know how, and my object is to give such hints from practical experience which, I trust, may prove serviceable to my brethren of the craft.

The almost innumerable varieties of *Pelargoniums* existing in our greenhouses at the present day owe their origin to hybridising and cross-breeding, having sprung from the comparatively insignificant species indigenous to the Cape of Good Hope. There is probably no family of flowering plants in existence that has so richly rewarded the labours of the hybridist as the *Pelargonium*, or that is used for decorative purposes in such a variety of ways. They can be had in flower throughout almost the whole of the year, and are useful alike for greenhouse, conservatory, hall, window, exhibition, and as cut flowers.

PROPAGATION.

The ease and rapidity with which they may be propagated is another great advantage. *Pelargoniums*, as will be easily understood, come freely from seeds, hence the almost astounding number of varieties in cultivation. If this system be adopted the seeds should be sown in the spring in shallow boxes or pans, well drained, and then filled to within an inch of the rim with finely sifted soil composed of two parts loam and one of thoroughly decomposed leaf soil, making the surface quite smooth. Damp the soil slightly if it is dry, and after allowing the water to drain through sow the seeds thinly and evenly, covering them to a depth of about a quarter of an inch. Place a sheet of glass over the top of the receptacle, but remember to remove it every morning in order to wipe off the moisture that will condense on the inner surface, and be careful to tilt the covering slightly immediately the plantlets push through the soil, increasing the ventilation as the plants attain size.

Put the seed boxes in gentle heat, and when the seedlings appear give sufficient water to keep them growing, but do not make the soil too wet, as *Pelargoniums* are somewhat impatient of moisture. When the seedlings are large enough to handle, prick them off singly into thumb pots, using soil similar to that in which the seeds were sown. Stand them in a house or pit near the glass, in a temperature of 50°, and admit sufficient air to prevent them becoming tall and weak. As the pots are filled with roots move the plants into others, 3 inches in diameter, using the same compost in not quite such a fine state. Encourage growth, but do not pinch the shoots unless the plants are intended for specimens. This is not often the case with seedling plants, the principal object being to get them into flower as soon as possible in

order to ascertain if there are any worthy of retention. All that are inferior to existing varieties should be destroyed. Five or 6-inch pots will be large enough to keep them in till they flower.

There are few plants that can be increased by cuttings more readily than *Pelargoniums*. Every properly matured joint or a bud with a leaf will usually form a plant, but cuttings made from the shoots in a moderately firm condition are more generally employed. Shoots with two or three joints ought to be taken early in spring, and four inserted round the edge of a 4-inch pot filled with two parts loam to one each of leaf mould and sand. Let these be accommodated in a temperature of 50° where they will root freely. They must be neither too close nor receive too much water, as they are liable to damp off under such conditions. When they are well rooted move them into thoroughly drained 4-inch pots, using soil similar to that in which the cuttings were rooted, but with rather less sand.

When growth commences pinch out the points in order to induce them to produce several shoots within 3 or 4 inches of the collar of the plants, and as soon as these are long enough tie them to the rim of the pot. If this is not done whilst they are young there is difficulty in getting them down low enough without considerable danger of breakage. When these shoots have made three joints pinch again to cause them to form more.

COMPOST AND TRAINING.

The final repotting for seedlings, as previously suggested, should be into 6-inch pots, which will be large enough for them to flower in the first year. The compost for this potting should be two parts good fibrous loam, one part each of leaf mould and well-decayed cow manure, with sufficient sand to keep it open. Place neat stakes to all plants requiring support. A little liquid stimulant will be all they require until flowering is finished, after which stand the plants out of doors in a sunny position to ripen the wood, giving no more water than is necessary to keep them from flagging. In about a month the plants will be ready to cut back. Each shoot ought to be shortened to the second eye, the plants placed in a frame or pit, and kept a little close and dry until growth has recommenced.

To induce this syringe every warm afternoon, but do not apply water to the roots until they have well started, or they may quickly suffer. When the shoots are an inch or so in length turn the plants out of their pots, and shake off most of the old ball, trimming the straggling roots a little, and replace the plants in pots two sizes smaller than those which they previously occupied. The compost for this potting should be two parts good fibrous loam, one part leaf mould, with a little decayed manure and silver sand. The potting should be done lightly, while watering must be very carefully looked to.

Keep the plants near the light, and sufficiently far apart to prevent their becoming drawn. As the shoots get long enough secure them down to the rim of the pot. They should be wintered in a good light house, and be placed near the glass, the night temperature being as nearly as possible 45°, with air given on all mild days. Cold currents must be allowed to pass through the plants. No more water than is necessary to keep the soil from getting too dry should be given in the winter. Stop the shoots about the end of October, and as soon as they have made an inch or two of growth move them into their flowering pots. The size of the plants will be a guide as to the size of the pots required. Those in 4-inch pots, with from six to ten shoots, do well in 7-inch pots, and so on in proportion, bearing in mind the vigour of the plants. The compost for this potting should be three parts good loam, one of well decomposed manure, with a 4-inch potful of any well-known artificial manure to each 3 bushels of the compost. The potting must be very firm.

If the compost is not wet it is impossible to pot them too hard, except in weak and short growing varieties, which should be potted rather lightly. As growth advances tie out the shoots, so as to keep them open and exposed to the light. If they are required to flower early they should not be stopped again, but if not desired until June, they may be stopped in February. As the days get longer they should be encouraged to make both root and top growth by closing the house early in the afternoon while the sun is shining upon it; and as soon as the flower buds are formed, assist them by the use of liquid manure once a week. About half an ounce of guano to 2 gallons of water will be strong enough to start with, then increase the guano to 1 oz. to 2 gallons of water.

As the weather gets warmer green fly is almost sure to make its appearance. As soon as it is discovered fumigate the plants, and be very particular to see that the plants are quite free from insects before the first flower buds open. If fumigating has to be resorted to when the plants are in bloom nearly all the open flowers will fall. After the plants have done flowering they may be stood out in the open air, as previously advised, to harden them. When the wood is firm and ripe they can be cut down and treated as already described.

Cuttings can be made from the shoots taken off at this time, and if sufficiently early, say the beginning of August, they will root freely in the open air in a bed made up of sand and loam. If on a slight bottom heat they will root all the quicker, but in the open air there is not so much loss through damping. When well rooted place them singly in 3-inch pots, in which they may remain until after Christmas, when they can be transferred to others 6 inches in diameter, and be treated as advised for the spring-rooted plants.

SELECTION OF VARIETIES.

The following is a short list of what I consider the best varieties:—Albert Victor, rich rose, edged white; Champion, white, shaded blush, lake blotch on lower petals, immense trusses, and fine habit; Countess,

large flower, of a distinct shade of cerise salmon, with white throat, good habit; Digby, grand, blush white, feathered maroon, crimped edges; Decorator, a fine variety, deep red, with dark blotches on upper petals; Dorothy, salmon, shaded rose, dark blotch on upper petals, very free; Duke of York, rose, with dark blotches on upper petals, of a vigorous habit; Duchess of Edinburgh, white, tinted blush, crimped edges;

light centres, fine dwarf habit; Kingston Beauty, white, with dark purple spots on upper petals; Madame Thibaut, white marble rose, immense truss, and good habit; Martial, rich crimson, top petals darker, a telling variety; Pearl, white, crimped edges; Prince George, nice shade of soft pink, blotched blackish maroon, enormous trusses; Purple Emperor, a very dark variety, bold flowers, and good habit;

FIG. 68—SOPHRONITIS GRANDIFLORA.

Edward Perkins, orange scarlet, with maroon blotch on upper petals; Emma Hays, clear soft rose, upper petals crimson, well formed and very free; Emperor of Russia, dark maroon crimson, marked white; Empress of India, intense shade of salmon orange, light throat, immense pip and truss, a grand variety; Goldmine, a very telling variety, colour rich orange scarlet; H. M. Stanley, soft shaded lake, upper petals deeper with

Radiant, crimson, top petals blotched darker, perfect habit; Sir T. Lawrence, purplish red shaded chocolate, white throat, good habit; Triomphe de St. Mandé, magenta, suffused crimson, truss very large, good habit; and Volonte National alba, pure white, massive flower, a grand addition.—(Abstract of a paper read by Mr. J. DIXON, Gardener, at a meeting of the Sheffield Chrysanthemum Society.)

BRIEF NOTES ON ALPINE FLOWERS.

CAMPANULA DRABIFOLIA.

ONE finds as a rule that growers of alpine flowers are disposed to view with more or less contempt the many dwarf annual flowers which would add greatly to the attractions of their rock gardens. They may, however, be made of use in several ways, among which may be mentioned the temporary furnishing of a space to be occupied permanently by some perennial plant, or carpeting the resting place of bulbs. From time to time I may have the opportunity of referring to some of these annual plants, a considerable number of which are not frequently seen.

The little Bellflower known as *Campanula drabifolia* is one which is excellently adapted for the rockery, not only on account of its intrinsic beauty but also because of its dwarf and unobtrusive habit. Compared with the *Portulaca* or *Mesembryanthemum tricolor*, sometimes used for the purposes mentioned, it may be comparatively dim in colour, but it is quite in keeping with its surroundings, and is, moreover, nearly as good on a rainy day as a sunny one. This is certainly an advantage in a climate like ours. I am somewhat in the difficult position, however, of recommending a plant of which one has to say that we do not know where seed can be obtained. I think there is little doubt that it can be procured from some of the larger seed firms, although not included in their catalogues. It is well worth being at some trouble to secure, so pleasing is it with its pretty flowers and neat habit of growth. The flowers of the type are of a pretty violet blue with a tinge in it of the purple so prevalent in the genus, and with a white tube. The flowers are very freely produced above the leaves, which, like the rest of the plant, are covered with little stiff hairs. There is also a white variety, but this looks ineffective in most positions. The whole plant is only about 3 inches high. It was to be seen growing a year or two ago on one of the beds in the arrangement of plants in the Royal Gardens, Kew. The *Draba*-leaved Harebell was introduced from the Island of Samos in 1823, and ought to have the treatment of a half-hardy annual.

RHODODENDRON PRÆCOX.

Your correspondent "A. D." performed a useful service in lately drawing attention to this beautiful early-flowering *Rhododendron*. I may perhaps be allowed to endorse all he says in its favour and to point out how valuable it is for the rock garden. There is, it is true, considerable variety in the way of shrubs suited for this purpose, but this little one yields to none in its beauty at so early a season as February and March. It is, I think, superior to either *R. ciliatum* or *R. dahuricum*, its parents, and in this garden it is greatly admired by those who see it at this time of the year, when its foliage is hidden by its rosy-peach coloured blooms. It appears to be quite hardy, having pulled through the extraordinary winter of 1894-95 without injury on the top of a rockery.

SAXIFRAGA BURSERIANA MAJOR.

Possibly there may be some who would like to know something regarding the remark made in these notes, on page 215, that "there are two varieties passing under the name of *S. Burseriana major*." It is unfortunately too true that the ordinary form of *Burseriana* is sometimes supplied for the major form, but in addition there are two distinct plants to be found under the name of the coveted and admired larger form. The true form keeps high in price. It has considerably larger flowers than any of the others. It also blooms considerably earlier than the typical *Burseriana*. A fair sized plant of this major form is very beautiful, although it must be said that the flowers always appear to me to have less substance than the others, and that they are produced less freely.

The variety sometimes seen under the same name, which we may for convenience sake call pseudo-major, has flowers little larger than the ordinary *Burseriana*, but it comes into bloom if anything a short time before major. The confusion is rather unfortunate, but it may be forgiven if one is eventually able to secure the three forms—viz., *Burseriana*, *B. major*, and *B. pseudo-major*. The last I received from an experienced cultivator who afterwards told me that a high authority on Alpine flowers said it was not the true major—an opinion with which I quite coincide.

MAIANthemum CONVALLARIA.

It is rather distressing for those who are acquainted with this little flower to have to search for it in the Kew Handlist. I believe I first got it a good many years ago as *Convallaria bifolia*, and it has also at various times appeared as *Smilacina bifolia* or *Maianthemum bifolium*, and now we must accustom ourselves to the name of *Maianthemum Convallaria*, which is Weber's title for it. It has also, I see, been called *Smilacina canadensis*. If we asked "An Old Boy" who has been ably pointing out the usefulness of learning the meaning of the botanical names of plants, he would tell us that *Maianthemum* means "May Blossom," from the time in which it blooms. From the specific name, which I take to be used as being the pre-Linnean generic one, we may safely make use of the English form, and speak of the "Lily of the Valley May Blossom."

Quite a union of pleasant sounding names, and a full recompense, surely, for being burdened by botanists with such a Latin name! It is a modest little flower, too, but although so shy and retiring in its ways has been figured in good books several times. This little May Blossom is a native of the northern temperate regions, and is found in some parts of Britain. It grows only 7 or 8 inches high, producing from each crown a couple of leaves and a raceme of from twelve to thirty very small white flowers. It possesses, as a matter of course, no brilliancy,

but is a pretty little plant in a moist and shady corner of the rock garden, where it can ramble among the stones with its creeping root-stocks. Although this "May Blossom" runs pretty freely, it can be easily kept within bounds.—ALPINUS.

(To be continued.)

NATURAL BEAUTY IN PLEASURE GROUNDS.

FORMALITY and a primness that chills are too often apparent in pleasure grounds, and the truth we need to grasp is the power of Nature to afford beauty. Let us idealise a little. It may be, we have broad lawns stretching outwards from two or more sides of the mansion to the very boundary. Dotted about are mixed clumps of grasses, shrubs, and small trees, carefully kept within limits which are strictly geometrical, viewed from walks as straight as a ray of light, or else bending in fantastic curves, made even when no obstacles block the way. These and a few other petty contrivances all tend in one direction—viz., the ousting of Nature to so-called Art.

Mentally viewing the subject, let us suppose ourselves at the outer limit or boundary. We have seen that closely shorn lawns are carried to this extreme, bordered probably by a belt of dark thought-saddening evergreens, which it may be are ineffectual to screen some ungainly object or objects just outside. Some 30 yards inwards a walk bisects the lawn, leaving between the outer belt and itself a strip of the aforementioned short grass, in which a group of Laurels are compactly arranged. Other artificialities may also exist.

Now, instead of machining the grass to the edge of the pleasure ground area, let us leave it slightly towsey, only using the scythe to restrain it from dire rampancy. Thus shall we have a beautiful mantle of the freshest green. Also, instead of having clumps of stiff Laurels placed so accurately in their various positions, we should much more enjoy the scene if a rotery and branchery (not a large one) could be formed—one which would appear as if Nature had made it—of old gnarled roots and branches of Oak, Elm, or Ash, having all the knots, fissures, and scars preserved, to add to them interest and beauty. Suppose we had the materials, our first thoughts would be as to where we might place them. This, of course, cannot be settled by mere statements on paper, especially so in this mental picture.

If we follow the general rules for beauty no glaring effect must be produced, no great piles of huge roots on view, and if the strip of lawn be a long straight stretch we must not have a great mound in the centre of the space, or yet at the ends. Better to have one or two small adornments blending with the herbage around them, and hidden each from the other, yet producing at different points a pleasing effect. Have any of you ever roamed through a neglected forest? If so, did you observe those huge limbs slumbering in negligent security, not too closely yet together? Through the same neglect which laid them there mosses and lichens have overspread them, wavy grass wanders lovingly among hardy Ferns, and, as if keeping guard over a sacred charge, the stately Foxgloves tower over all. Leaves blow in and about them, depositing material for new vigour and fresh embellishment.

Cannot we then reproduce a forest picture in a garden? Have your rugged tree roots set in a fashion indicative of upturned trees, one or two crooked limbs lying peacefully at the base of a gentle slope, which should taper away gradually on that side least exposed to the admirer. We only wish a few roots carefully placed, or a tree trunk and limbs somewhere near, lying well firmed on a carefully studied outline, an outline which Nature herself might have figured. It will also be necessary to have a background, a rest for the eyes. Nothing it seems to me could be better than a considered selection of *Rhododendrons*. These should spring from the base of the bank on the boundary side, so that the bank with its roots and branches lie between them and the observer from the walk. Dwarf narrow-leaved varieties of a white or soft pink colour should be to the front, while backwards those of more prominent foliage and darker hue of bloom might be more sparsely diffused, allowing room for the spread of the strong arms and haughty heads of the Giant or Cow Parsnip (*Heracleum giganteum*). These, when as if aimlessly traced away back in the depths of green, have an appearance unique in their dignified serenity.

Might I suggest the use of those gems the Birches? The silvery white bark, the long, pendent, whipcord-like streamers called branches, or perhaps branchlets, and the lovely serrated leaves, give this tree, at least many of its varieties, almost incomparable delicacy. Many species are known, but for brevity and aim I shall only mention the pendent form commonest with us, *Betula alba Youngi*. I would have these hovering on the outskirts acting as rearguards. And could we not use the light, hardy, and valuable Larch trees as protectors and guardians of all within the pleasure ground limits?

It will be seen that the choice has been to render the completed whole one of lightness, restful, and interesting beauty. It would be bad taste, I fear, to try further improvements by dotting about more of shrub and tree growth. Simplicity weds with negligence in Nature. We might add a few climbing Roses, twining these up and around the stems and lower branches of the Birches. Space hampers my detailing or even suggesting more of these twining or climbing plants, the healthful elegance of which are known to all.

But are we to leave out of thought the jewels—the bonnie wee flowers? No. The Snowdrop, so fresh and early, would be at home there. Also I love the wax-like white Crocus, the Poet's Narcissus, the sweet-scented Woodruff, and the *Campanula turbinata alba*, which give

choice of white flowers. *Scilla sibirica*, wild Hyacinths, *Chionodoxas*, Forget-me-nots (*Myosotis*); the trailing and wild Vetch, are among a long list of differing blues. *Primula vulgaris*, the common Primrose; Cowslips, *Alyssum saxatile compactum*, a root or rockwork gem; *Doronicums*, for moist, shady corners, give the yellows. Then we may have the varied colours of the cultivated Primroses. The red hues and modifications are supplied from *Geranium Robertianum*, which should have an exalted position; the Fairy Orange Moss, with scarlet berries; the Mediterranean Heath, and carpets of the various wild Thymes; ochre coloured Ragworts, and numerous dwarf herbaceous plants with distinct and telling colours; carpeting these throughout the grass, in and about the rootery and bases of the trees—not in isolated patches, but in mantles widespread in harmony. Arabis, Aubrietias, Foxgloves, and, oh! never forget the Ferns, so fresh, free and graceful; we shall consider them subsequently. Enough is said at present to make us feel that "Gardening is the purest of human pleasures, and the greatest refreshment to the soul of man."—A YOUNG SCOT.

EXCRESCENCES ON PEACH TREE ROOTS.

I AM sending you some Peach tree roots, with excrescences. The trees were first grown outside on a south wall, and although they have the disease outside, they grow and bear good crops; but when I bring them into the Peach house they soon get a great deal worse, until the trees die entirely. The Peach house has only been built about fourteen years; the border was well made and drained at the time, and the trees grew well the first seven or eight years. There is a good deal of old lime rubbish in the border, which makes it rather porous, and requires water about once a fortnight in summer. It seems rather a worse case than any I have read about in books or papers. Will Mr. Abbey kindly examine them, and let me know the cause, and if possible the cure?—J. L.

[The roots are much swollen here and there, the excrescences being two to three times as thick as the normal roots, and occupy about half of their length. This is a very serious state of things, and quite distinct from suckering, knobs in that case being formed on the roots, adventitious buds produced, and ultimately sucker-growths appear in abundance. The roots are quite healthy where there are no excrescences, having clear stout bark and sound wood, and the fibres are clean, plentiful, and healthy.]

The excrescences consist of both dead and living parts, having much the appearance of a bad case of canker, and may not inaptly be termed, as roots so affected have frequently been, root canker. In the dead part I first came across some white worms, one-eighth to three-sixteenths of an inch in length, which are the young of the root-hair sucking white worm (*Enchytraeus Buckholzi*), and common on roots and stems undergoing decay. This worm has a bad character, but it certainly was not the cause of the excrescences on the roots. The worms died instantly in a solution of aniline, one part in twenty parts water, not so much as once writhing.

Following up the dead tissue to the living, I found there a host of mites nestling on the living tissue in the crevice formed by the bark and wood. To seize two between the tweezers and place them in a drop of aniline solution was the work of a moment, and looking through the eye-piece of a small microscope enlarging 25 diameters I had them represented $\frac{7}{8}$ -inch long, female and $\frac{5}{8}$ -inch long, male. They never moved after being placed in the solution of aniline, 1 in 20 parts water. This was very satisfactory, for I do not care to see even microscopic creatures writhe and suffer as I have seen in the case of eelworms, therefore have striven to get hold of something that would render them as "still as mice."

The excrescences, then, are caused by the root-mite *Rhizoglyphus robini*, *Ciaporède*, which is only distinguishable from the bulb-mite, *R. echinopus*, by the female having a very thick and clumsy third pair of legs, thus throwing the fourth pair further back. The specimens, however, are only in the six-legged stage. They are whitish grey, pellucid, and appear like a speck of jelly with an ordinary pocket lens say magnifying 6 diameters. The very interesting creatures belong to the family of the cheese-mite, *Tyroglyphidae*.

The root-mite causes the excrescences by biting and sucking at the cellular tissues of the roots, killing some cells, and the tree on its part producing new ones to exclude the parasite, hence the excrescence gradually enlarges, and this goes on year by year until the dead tissue surrounds the roots attacked, then the tree dies. This may not occur for years, but the affected trees become sickly and go off by degrees. It affects trees both outdoors and under glass, and is very widespread. I have found it on nearly all leguminous plant roots that have been examined for nitrogenous nodosities, and is frequently associated with eelworms. In pursuing my investigations I was led to seek for something that would kill the mites and eelworms without prejudice to the "bacteroids"—the micro-organisms that convert free into assimilable nitrogen, and have succeeded in doing the best possible for the suffering plant.

The substance is aniline (C_6H_7N). As an insect killer nitro-benzole ($C_6H_5NO_2$) would perhaps suit the purpose as well, but there are "agonies" in it, whereas in aniline solution, 1 in 20 parts water, there is nothing of the kind with micro-animals, and even such large creatures as black ants die in one minute. The solution is as clear as water, hence cannot stain foliage, and does not injure the most delicate leaves. Any lady may use it in the drawing-room, as it is not in the least offensive,

but on the contrary, a faintly pleasant smell. The finest possible film from an atomiser kills thrips and all of that ilk; indeed, what in the insect way it will not kill, including mites and eelworm, I do not know, but anyone giving it a trial can convince the Editor and myself by sending specimens to the former. Send 'em alive, neatly packed in a little damp, not wet, moss, and I may perhaps send a good account of them in return.

The cure (if any) for these mites is chemical manures. I do not recommend any in particular. There is Thomson's (long proven), Pearson's (a canker cure), and no end of others advertised. They contain the essential mite-killers, nitric acid and chlorine, and the essential food of the higher plants. I may, however, refer to dissolved bones, 3 parts; muriate of potash, 2 parts; and nitrate of soda, 1 part; mixed, using 2 to 4 ozs. per square yard as a suitable application in this case. For directly killing the mites Little's soluble phenyle, 1 in 96 parts water, or 1 gill (quarter pint) to 3 gallons of water, or, if your correspondent likes to keep up with the highest pace and beat the record, he can use aniline, 1 in 20 parts water, or perhaps it would act quite as well on root-pests in the proportion of 1 in 100 = 1 lb. aniline to 10 gallons water. This, however, is subject for experiment.—G. ABBEY.]

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL, APRIL 13TH.

THESE gatherings seem to become more popular every week, and the one of this date must have made a record. The Floral and Orchid Committees had a large number of superb exhibits before them, while with the Narcissus and Fruit Committees quality took the place of quantity. Herewith we note a few of the most prominent exhibits.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); Rev. W. Wilks, and Messrs. T. Francis Rivers, J. Cheal, W. J. Empson, W. Pope, T. Fife, W. H. Divers, G. Reynolds, J. Smith, C. Herrin, W. Bates, J. Willard, W. Farr, J. A. Laing, G. T. Miles, A. F. Barron, A. Dean, and J. Wright.

The excellent tables of vegetables and fruit formed the chief feature of the meeting, and they were certainly most creditable to the exhibitors; very few products were placed on the Committee table. Mr. John Crooke sent from Forde Abbey, Chard, highly coloured Dumelow Seedling Apples, also very good Sturmer Pippin, and a vote of thanks was awarded. Mr. B. C. Harris sent from Jersey five Pears of "Belle de Jersey"—Uvedale's St. Germain (vote of thanks). Sir Trevor Lawrence, Bart., sent a sample of Anserinus Bonus Henricus—really a bunch of the Lincolnshire Mercury, known also as Good King Henry, Algood, and other names—*Chenopodium Bonus Henricus* of Linnaeus. Mr. Divers remarked that the plants grew wild around Belvoir, and undoubtedly Mercury beds have occupied a portion of hundreds of cottage gardens in Lincolnshire and surrounding counties for generations. The vegetable is also known as Perennial Spinach, and grows like a weed.

Turning to the side tables, Mr. G. Wythes, Syon House Gardens, had an extensive and highly meritorious collection of vegetables, not large bulky produce, but in the majority of instances models of table quality. These included all kinds of root and green crops, including firmly hearted Cabbages, Sutton's Favourite, much admired; Cucumbers, New Potatoes, Beans, Seakale, Asparagus, and Mushrooms, as well as excellent La Grosse Sucrée Strawberries and St. John's Figs. A silver-gilt medal was granted unanimously.

Mr. W. J. Empson furnished a table admirably and artistically with fruit and vegetables. A row of Carter's Early Morn Pea in pots at the back; in front, Royal Sovereign Strawberry in pots, also splendid gathered fruits, very noticeable, as well as Carter's Early Cabbage and Perfection Broccoli, excellent Seakale and Radishes also being represented (silver Knightian medal).

Mr. W. H. Divers sent from Belvoir thirty-six dishes of well kept Apples, a worthy contribution from a private garden at this period of the year (silver Banksian medal).

Mr. W. Farr, gardener to A. Pears, Esq., Isleworth, sent a small but very interesting exhibit consisting of a central basket of fine Strawberries, surrounded by new Grapes, perfectly coloured and old (shrivelled), splendid Mushrooms, and good Dwarf Beans. Considering the larger exhibits, and the medals awarded, a bronze was mentioned for the smaller but scarcely less meritorious assortment; but eventually, and as it proved far more acceptable to the exhibitor, a cultural commendation was unanimously awarded.

VEITCHIAN FRUIT PRIZES.—The competition was not great. For Apples the first prize was awarded to Mr. C. Ross, Welford Park, with Lord Burghley; second, Mr. C. Herrin, Dropmore, with Sturmer Pippin. No prize was awarded for Pears. A dish of Bergamotte Esperen arrived in the Hall after the Judges had left.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. H. B. May, H. Herbst, J. Fraser, J. H. Pitt, R. Owen, J. Jennings, J. T. McLeod, R. B. Lowe, C. J. Salter, C. Jeffries, J. D. Pawle, C. E. Shea, E. Mawley, G. Gordon, C. E. Pearson, J. W. Barr, H. J. Cutbush, J. Laing, H. J. Jones, D. B. Crane, E. Beckett, J. Walker, W. Bain, R. M. Hogg, J. Fraser, T. W. Sanders, J. Hudson, G. Paul, C. Blick, H. Turner, and R. Dean.

Mr. Mallender, gardener to Miss Mellish, Hodsock Priory, Notts, sent a small, though pleasing, collection of Narcissi, and Mr. Aitkin, gardener to G. Webb, Esq., Sittingbourne, showed some well-berried branches of *Aucuba japonica*. Mr. Bain, gardener to Sir Trevor

Lawrence, Bart., Burford Lodge, sent a varied collection of Anthurium flowers, which were very effective.

Mr. Rumsey of Waltham Cross sent a nice exhibit of Rose flowers, including Mrs. Rumsey (the firm's latest novelty), Niphetos, and others. Mr. J. F. McLeod, gardener to J. P. Morgan, Esq., Dover House, staged a very effective group of forced plants, including Azaleas, Spiræas, Genistas, and Boronias, interspersed with Palms and fine-foliage plants. Very effective was the large display of Daffodils staged by Messrs. Barr & Son, Covent Garden. To say that the cream of Messrs. Barr's large collection was represented is sufficient to give an idea of the excellence and magnitude of the exhibit.

Mr. George Mount, Canterbury, showed Roses in the style that has made him well known at the Drill Hall. Conspicuous in the exhibit were superb blooms of Mrs. John Laing and well-flowered plants of Crimson Rambler. Mr. H. A. Chapman, gardener to Captain Holford, Tetbury, Gloucestershire, sent a splendid collection of Hippeastrums, which were much admired. The exhibit contained many distinct varieties, several of which were very striking. Mr. J. Walker, of Thame, Oxon, was represented by a charming exhibit, comprised of Niphetos and Maréchal Niel Roses. Very neat and effective was the collection of Daffodils staged by Messrs. Jas. Veitch & Sons, Chelsea. Most of the best forms were represented, giving evidence of the attention to which these flowers are subjected at the hands of the famous Chelsea firm.

Messrs. Kelway & Son, Langport, staged a handsome collection of cut blooms of double Cinerarias, amongst which the colours were well diversified. Messrs. W. Cutbush & Sons, Highgate, arranged an effective exhibit of Boronias, Ericas, Prunus, Magnolias, Staphyleas, Palms, Ferns, and Calla Elliotiana. Miscellaneous foliage and flowering plants were staged by Messrs. J. Laing & Sons, Forest Hill. There were well-grown Cytisus, Clivias, Crimson Rambler Roses, Dendrobiums, Ericas, Ferns, Palms, Crotons, Dracenas, and the black-throated golden Arum called Pentlandi. Mr. H. B. May, Upper Edmonton, sent a collection of clean, finely grown foliage plants. Mr. J. A. Horrell, 295, Southampton Street, Camberwell, sent specimens of his improved acme labels, which are certainly very useful; and Mr. E. Mawley, Berkhamsted, beautiful cut Roses.

Roses in pots were handsomely shown by Messrs. Paul & Son, Old Nurseries, Chesham. The varieties represented included Captain Hayward, Souvenir de S. A. Prince, Mrs. S. G. Crawford, Elise Fugier, Gustave Piganeau, and others. An interesting collection of alpine flowers also came from this source. Messrs. R. Wallace & Co., Colchester, sent a small exhibit, comprising charming Erythroniums, Tulips, Iris caucasica, and Fritillaria pudica. Mr. W. Fyfe, gardener to Lord Wantage, Lockinge Park, sent superb bunches of the fragrant Fortune's Yellow Roses. The blooms were of excellent quality.

The Rev. G. H. Engleheart, Appleshaw, Andover, sent a considerable collection of hybrid and seedling Narcissi of his own raising. Many of the specimens were of great merit, and they formed a conspicuous exhibit. Mr. Downe, gardener to J. T. Bennett-Poë, Esq., staged a large collection of Narcissi in great variety.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, De B. Crawshaw, H. M. Pollett, C. J. Lucas, H. Ballantine, W. H. Young, W. H. White, W. H. Protheroe, H. J. Chapman, A. H. Smee, E. Hill, F. J. Thorne, W. Cobb, A. Mason, T. B. Haywood, S. Courtauld, and J. Douglas.

Messrs. F. Sander & Co., St. Albans, were strong in Orchids as usual, sending well-grown examples of Odontoglossum vexillarium, Dendrobium Phalaenopsis Schölerianum, Cattleyas, Phaius Owenianus, Odontoglossums, and some charming plants of Lycaste Skinneri. Mr. W. Whiffen, gardener to J. Bradshaw, Esq., Southgate, N., staged a pleasing collection of Orchids, largely composed of Odontoglossums and Cymbidiums. Mr. A. Methven, gardener to Marquis Camden, Lamberhurst, sent a fine display of Dendrobiums in several varieties.

Mr. G. Cragg, gardener to W. C. Walker, Esq., Percy Lodge, Winchmore Hill, sent Cattleyas in fine condition; as did Mr. Downe, gardener to J. T. Bennett-Poë, Esq., Chesham. His were handsome specimens of Cattleya citrina. Mr. W. H. White, gardener to Sir Trevor Lawrence, Bart., Dorking, staged Masdevallias, Dendrobiums, and other Orchids of considerable interest. Mr. F. J. Thorne, gardener to Major J. Joicey, Sunningdale, sent very fine specimens of Epidendrum bicornutum, which were examples of good culture.

Quality and variety characterised Messrs. J. Veitch & Sons' (Ltd.) group of Orchids. The plants were all splendidly grown, and included Masdevallias, Cattleyas, Odontoglossums, Epidendrams, Cymbidiums, and several others. Mr. Duncan, gardener to C. J. Lucas, Esq., Warnham Court, Horsham, staged a collection of spikes of Odontoglossums. Mr. S. Cooke, gardener to De Barri Crawshaw, Esq., Sevenoaks, sent a collection of Odontoglossums.

CERTIFICATES AND AWARDS OF MERIT.

Amaryllis Brenda (J. Veitch & Sons, Ltd.).—A rich, deep variety with handsomely formed crimson flowers (award of merit).

Amaryllis Chimbarosa (H. Chapman).—The colour of this is very deep crimson (award of merit).

Amaryllis Duke of York (H. Chapman).—Fiery scarlet is the colour of this variety (award of merit).

Amaryllis Ignacite (J. Veitch & Sons, Ltd.).—White is the ground colour of this variety, the splashes thereon being purplish crimson (award of merit).

Amaryllis The Czar (H. Chapman).—A rich velvety crimson variety of much beauty (award of merit).

Amaryllis Thunberg (J. Veitch & Sons, Ltd.).—An immense flower, of which the colour is scarlet with an orange shading (award of merit).

Amaryllis Topaz (J. Veitch & Sons, Ltd.).—Brick red margined white in this flower make a charming variety (award of merit).

Erythronium revolutum (R. Wallace & Co.).—This is now flowering in this country for the first time. The colour is white, delicately flushed with rose (first-class certificate).

Fuchsia Addington (H. Cannell & Sons).—This is said to be a hybrid between *F. fulgens* and *F. splendens*. The colour is bright crimson scarlet, while the habit infers that it would form a handsome standard (award of merit).

Lælio-Cattleya Digbyana-Trianæ (J. Veitch & Sons, Ltd.).—One of the most beautiful Orchids that was in the Drill Hall. The sepals and petals are delicate purplish rose, while the lip is quite the style of *Lælia Digbyana*. The centre is golden, and the throat rose (first-class certificate).

Muscari conicum (Barr & Son).—A very rich blue Grape Hyacinth, with particularly large spikes (award of merit).

Narcissus Beacon (Rev. G. H. Engleheart).—This is of the Parvicoronati section. The crown is brilliant orange red, and the perianth segments yellow (award of merit).

Narcissus M. de Graaff (T. S. Ware).—A small flower with white segments and a lemon coloured cup (award of merit).

Narcissus Snowdrop (Rev. G. H. Engleheart).—A singularly beautiful flower of a delicate creamy white hue. The trumpet is straight, and the segments broad and blunt (award of merit).

Odontoglossum Andersonianum Danhurst variety (E. Short).—A handsome variety. The creamy sepals and lip have bright brown blotches of which the petals are free (award of merit).

Odontoglossum Wilckeanum Queen Empress (W. Ballantine).—A superb Orchid. The centre of the sepals and lip are almost wholly bright brown, the margins and tips being golden, as is the base. The petals are spotted as well as blotched with brown (first-class certificate).

Ornithogalum grandiflorum (J. Laing & Sons).—After the style of *O. arabicum*, but lacking the familiar black spot (award of merit).

Solanum tuberosum variegatum (E. Beckett).—A beautifully white and green variegated Potato (award of merit).

Tropæolum Phæbe (H. Cannell & Sons).—Golden yellow, with scarlet and crimson blotches, is the colour of this *Tropæolum* (award of merit).

Zygopetalum Perrenoudi superbum (J. Veitch & Sons, Ltd.).—A hybrid between *Z. maxillare Gautieri* and *Z. intermedium*. The narrow sepals and petals are brown, edged greenish yellow, and the lip is blue margined white (first-class certificate).

MEDALS.—As will readily be understood the medals were numerous and included to exhibits before the Floral Committee silver-gilt Flora, Mr. J. F. McLeod; silver Flora, Messrs. H. Chapman, W. Cutbush and Son, Paul & Son, and G. Mount; silver Banksian, Messrs. H. B. May, J. Walker, W. Rumsey, and W. Fyfe; bronze Banksian, Messrs. E. Mawley and W. Bain. Orchid Committee silver Flora, Messrs. F. J. Thorne, J. Veitch & Sons (Ltd.), and J. Bradshaw; silver Banksian, Messrs. W. H. White, De B. Crawshaw, C. J. Lucas, and Marten.

PRUNUS TRILOBA.

ANYONE who has seen this Plum in full flower cannot fail to be impressed by its beauty, yet it is not grown on nearly such a large scale as its merits entitle it to be. At the present time (March 29th) it is to be seen in flower in several places at Kew. Two beds of it are to be seen within a short distance of the main entrance, and a large plant may be seen in full flower on a wall close to the succulent house. Although perfectly hardy, and doing well in beds or as specimen plants on the lawn, it is as a wall plant that this Plum is seen at its best; the wood then gets thoroughly ripened, and flowers are produced thickly along the full length of the previous year's growth. The individual flowers are 1 inch across, delicate pink in colour, and produced before the leaves.

When planting good soil should be given, and when grown against a wall, after the main branches have attained the desired length, all other growth should be spurred-in as soon as flowering is over; this will allow a long growing season for the production of flowering wood for the ensuing season. Only the main branches should be secured to the wall, the others (from the spurs) being allowed to hang in a natural and graceful manner. The average length of the yearly growth is about 2 feet. China is the home of this beautiful hardy plant.—W. D.

INCREASING CHURCH FUNDS.—"It may interest many people to know that the restoration of St. Bartholomew-the-Great Church, West Smithfield, London, has been promoted to the extent of £120 by the sale during Lent for the last few years of the pods of a kind of Trefoil called Calvary Clover at the price of 6d. each pod. It is in many ways an interesting plant," says a writer in a daily contemporary. "The leaves have a blotch at the base of each leaflet, bearing quite a striking resemblance to a spot of fresh blood, which gradually dies away as the plant grows. The pod is spirally wound into a ball bearing numerous interlacing thorns on its margin, and when unwound, which is easily done, is remarkably like a crown of plaited thorns. It seems to be the custom to sow the seeds on Good Friday. They are still to be had of the vergers at the church in aid of the work going on in the church."

SCHIZOCODON SOLDANELLOIDES.

FEW exhibits attract more attention than the beautiful little *Schizocodon soldanelloides* (fig. 69). It was brought by the exhibitor from Miganoshta, Japan, in 1891, named at Kew, and stated by the authorities there to have been the first living plant brought to England. It was first shown at the Crystal Palace in the spring of 1892, and referred to in the *Journal* at that period as bearing a resemblance in foliage and flowers to *Shortia galacifolia*. It is a dwarf plant, attaining to a height of 2 to 3 inches only, and bearing its charming rosy flowers very freely. A marked feature of the latter is the deep laciniation of the segments which makes the flower look as if fringed. It is a most beautiful little plant, and it is to be hoped that it will seed readily, so that a stock may be procurable. We should be interested to hear whether such is the case or not. The plant has proved quite hardy during the past winter, and it may therefore be classed as a valuable addition to the list of choice outdoor plants. We trust this information will be of assistance to "A. J. B."

SPRING SHOWS.

BRIGHTON.—APRIL 6TH AND 7TH.

THERE was a marked improvement in this show, and throughout competition was keener than usual. One of the most attractive features was a mantlepiece, mirror, and imitation fire screens, the mantle, 5 feet by 1 foot, to be dressed with plants. It is a new class for Brighton, and was very successful. Mr. E. Meachen, gardener to Mrs. Armstrong, Woodslee, Preston, was ahead of Mr. G. Miles, Dyke Road, Brighton, with a remarkably neat arrangement of *Asparagus*, *Masdevallia*, and *Isolepis gracilis*.

In the chief class for groups, Mr. G. Miles beat Mr. E. Meachen handsomely, his arrangement being particularly neat and graceful. In both of the foregoing classes Mr. H. Anscombe, Bristol Road Nursery, Kemp Town, was a creditable third. Mr. G. Miles also won for a table of flowering plants, this time being closely followed by Mr. H. Anscombe. Orchids were fairly good, the best pieces being *Dendrobium Dalhousianum* and *D. thyrsiflorum*; also a grand piece of *Cypripedium philippinense* contained in the winning table from Mr. H. Garnett, gardener to R. G. Fletcher, Esq., Mount Harry, Preston.

Hyacinths, Tulips, Lily of the Valley, and other pot plants were very good. Mr. W. E. Anderson, gardener to S. Cowell, Esq., Melodia, Preston Park, was ahead for twelve Tulips in a strong class, and Mr. H. Anscombe, Kemp Town, for a similar number of Hyacinths. For twelve pots of Lily of the Valley, Mr. A. E. Golding, gardener to H. S. Voules, Esq., Dyke Road, Brighton, won with some grand examples, but was closely followed by Mr. L. Wickens, gardener to Mrs. Dawson Rowley, Chichester House, Kemp Town.

Mr. J. Hill, gardener to M. Wallis, Esq., Springfield, Preston, won for six pots of *Lachenalia*s; Mr. C. M. Carter, gardener to F. Freeman-Thomas, Esq., Ratton, Withdean, for double Violets; and Mr. W. E. Anderson, gardener to S. Cowell, Esq., for six well flowered *Freessias*. *Marguerites* and pot *Narcissi* were extra good; Messrs. W. Miles & Co., Church Road, Hove, taking first in each class; Mr. M. Tourle, gardener to F. Barchard, Esq., Little Horsted, coming very close for the pot *Narcissi*. In a class for twelve bunches of cut *Narcissi*, Mr. M. Tourle was well ahead, staging one of the best collection we have seen. The twelve pots of *Cyclamen* from Mr. E. Murrell, gardener to Mrs. Jenkins, Burgess Hill, were also worthy of special mention. Show and Zonal *Pelargoniums* were neither so good nor numerous as usual here. In a class for nine greenhouse *Azaleas*, Mr. H. Naylor, gardener to Mrs. Macdonald, Preston, had some good specimens. Six *Mollis* varieties found Mr. G. Miles, Dyke Road Nursery, ahead, and also in a class for six *Lilium Harrisii*.

Some of the non-competitive exhibits were extra good. A grand group came from Messrs. Laing & Son. Messrs. Balchin & Sons also had a most effective stand; Messrs. Barr & Sons sending a table of *Narcissus* and other spring-flowering bulbs. There were good cut *Roses* and seedling *Carnations* from Mr. G. W. Piper, The Nurseries, Uckfield, and also plants of *Crimson Rambler*, well covered with flower.

AURICULA AND PRIMULA.—APRIL 13TH.

ON Tuesday last the annual show of the southern section of the above Society was held at the Drill Hall in conjunction with the meeting of the R.H.S. Owing to the early date of the show the exhibits were not quite so numerous as in previous seasons, though the quality throughout was quite up to the usual standard. The flowers being young looked fresh and sturdy, and for this reason the early date of the show was an advantage. Below is given the list of the chief prize-winners.

In the class for twelve dissimilar Auriculas, Mr. A. J. Sanders, gardener to Viscountess Chewton, Cobham, was placed first with fine flowers of Rev. F. D. Horner, Richard Headley, Mrs. A. Potts, George Rudd, George Lightbody, Mrs. Dodwell, Prince of Greens, Heroine, Acme, Abbé Lizst, Rachel, and John Simonite. Mr. C. Phillips, Bracknell, gained second prize, also showing good flowers. Mr. P. J. Worsley, Clifton, came third; and Mr. J. T. Bennett-Poë, Ashley Place, S.W., fourth, these comprising the whole of the competitors in the class. Mr. C. Phillips had the best half dozen Auriculas, showing Mrs.

C. Phillips, Miss Bennett, Rev. F. D. Horner, and George Rudd in good condition. Mr. A. J. Sanders was justly placed second, Messrs. J. T. Bennett-Poë and P. J. Worsley following third and fourth in the order named.

Mr. Smith, Bishop Stortford, was first with four Auriculas, showing Heroine, Acme, Rev. F. D. Horner, and Rachel. Mr. A. R. Brown, Birmingham, was second; and Mr. J. Gilbert, gardener to Rev. L. R. Flood, Merrow Rectory, third. Mr. A. R. Brown was first for two Auriculas with Heather Bell and George Lightbody; Mr. W. Smith was second; third, Mr. J. Gilbert; fourth, Mr. A. Fisk, Broxbourne; and fifth, Mr. Coulling, gardener to W. W. Palmer, Esq., Shortlands, Kent.

The first prize for fifty Auriculas was well won by the Guildford Hardy Plant Company, who showed compact plants with sturdy footstalks. Twenty varieties were specified to be represented, and these included Buttercup, Lord of Lorne, Acme, Heroine, Black Bess, Friar Tuck, Mrs. A. Potts, Heather Bell, and Phyllis. Mr. James Douglas, gardener to Mrs. Whitbourn, Great Gearies, was a good second, though

FIG. 69.—SCHIZOCODON SOLDANELLOIDES

his plants were not quite so regular as those of the former, and the third prize went to Mr. A. J. Sanders.

In the class for a single specimen of green-edged Auricula Mr. A. J. Sanders was first with Rev. F. D. Horner; second, Mr. C. Phillips; third, the Guildford Hardy Plant Co.; fourth, Mr. C. Phillips with the same variety; fifth and sixth, Mr. Jas. Douglas with Abbé Lizst; and seventh, Mr. W. Smith with J. Hannaford; eighth, Mr. P. Hemnell with Prince of Greens. Mr. Jas. Douglas had the best grey-edged specimen with George Lightbody; second, Mr. C. Phillips; third, Mr. A. J. Sanders with the same variety; the Guildford Hardy Plant Co. was fourth with Marmion; fifth, Mr. W. Smith with Geo. Rudd; sixth, Mr. Walker with Grey Friar; seventh, Mr. J. T. Bennett-Poë with George Lightbody. Mr. J. Douglas was first with a white-edged specimen, showing Acme; second, Mr. C. Phillips; third, Mr. J. T. Bennett-Poë with the same variety; fourth, Mr. W. Smith with Geo. Rudd; fifth, Mr. C. Phillips with Geo. Lightbody; sixth, Mr. Douglas with Acme; seventh, the Guildford Hardy Plant Co. with the same variety; and eighth, Mr. J. Douglas with Rachel. Mr. J. Douglas was first with a single self specimen, showing Mrs. Potts; second, Mr. A. Fisk; third, the Guildford Hardy Plant Company, all with the same variety; fourth, Mr. C. Phillips with Mrs. C. Phillips; fifth and sixth, Mr. P. J. Worsley with Heroine; seventh, Mr. A. J. Sanders with Viscountess Chewton; and eighth, Mr. T. Barefoot with Heroine.

In the Alpine section Mr. Chas. Turner, Slough, took the first prize with twelve, showing Diamond Jubilee, Countess, Exquisite, Defiance, Mingo McGeorge, Bella Wheelwright, Charles Phillips, Unique, John Beswick, Nellie, Sunrise, and a seedling. Mr. C. Phillips was a fair second; Mr. J. Douglas third; Mr. A. J. Sanders fourth; and the Guildford Hardy Plant Co. fifth. Mr. Chas. Turner also had the best half dozen Alpines, showing Countess, Sunrise, Edmund Shaw, Nellie, Chas. Turner, and a seedling in good form. Mr. C. Phillips was placed second; and the third, fourth, and fifth prizes went to Messrs. W. L. Walker (Reading), Jas. Douglas, and J. J. Keen (Southampton) in the foregoing order.

Mr. W. L. Walker had the best four Alpines, showing fine blooms of Ormonde, Defiance, Olivia, and J. F. Kerr. Mr. J. J. Keen was a fair second; Messrs. A. Fisk, J. Gilbert, and J. T. Bennett-Poë following

third, fourth, and fifth. Mr. Walker had the best single specimen of Alpine with gold centre, showing Ormonde; second, Mr. A. Fisk with Hotspar; third, Mr. J. Gilbert with Mingo McGeorge; fourth, Mr. J. J. Keen, with a seedling; fifth, Mr. Charles Phillips with Evelyn Phillips. Mr. Walker was first with a single specimen with cream centre, showing Thetis; second, Mr. Walker with Defiance; third, Mr. A. J. Sanders with John Gilbert; fourth, Mr. Charles Phillips with Perfection; and fifth, Mr. J. Gilbert with Bessie. The Guildford Hardy Plant Co. had the best twelve Fancy Auriculas, showing Bronze, Innocence, Rolts' Green, Khartoum, Belle, Old Gold, and several seedlings. The second place was taken by Mr. James Douglas.

Mr. A. J. Sanders took highest honours with twelve Polyanthus, exhibiting well flowered plants. Mr. Jas. Douglas was a good second, and Mr. George Dixon, Chelford, third. Mr. Jas. Douglas had the best dozen single Primroses, the plants being well bloomed. The second prize was creditably won by Mr. A. J. Sanders. Mr. J. Douglas was first with six double Primroses, The Guildford Hardy Plant Company second, and Messrs. Paul & Son, Cheshunt, third.

Mr. Jas. Douglas obtained first prize with twelve Primulas of distinct species or well marked varieties, the exhibit being very effective. Messrs. Paul & Son took the highest award with six Primulas, subject to the same conditions as the above. Mr. Jas. Douglas had the best basket of Polyanthus and Primroses arranged for effect, the Guildford Hardy Plant Co. being second, and Messrs. Paul & Son third. Mr. Jas. Douglas also showed a most effective collection of Primulas and Auriculas, which took first prize, the Hardy Plant Co. following a good second. Mr. Jas. Douglas was granted a first-class certificate for Alpine Auricula Duke of York, and also for a green-edged Auricula Greenfinch, also for a gold-centred Alpine, Mrs. Markham. Mr. Walker obtained first-class certificate for gold-centred Alpine Ormonde and cream-centred Alpine Olivia.

PRESENTATION TO MR. JAS. DOUGLAS.

A pleasant feature in connection with the above Show was the presentation to Mr. Jas. Douglas of a testimonial on his retirement from active connection from the Carnation, and Auricula, and Primula Societies. In the unavoidable absence of Sir John Llewelyn, the presentation was made by Martin R. Smith, Esq., at the annual dinner, at the Hotel Windsor. The Chairman spoke in eulogistic terms of the service rendered in the past by Mr. Douglas in the interest of the two Societies named, and added that it gave him great pleasure to make the presentation, which took the form of a handsome clock, value £14 10s., and a cheque for £38, making a total of £52 10s.

Mr. Douglas made a suitable reply, in which he tendered his thanks to the Hon. Secretary, Mr. Henwood, for the assistance he had received from him in the past, and for the efforts he had taken in getting together the testimonial. He further thanked those present and others who had subscribed for the honour they had done him. Mr. Douglas spoke further of the able florists who had been the first pioneers of the Societies, and hoped that they would still flourish under the auspices of the younger men, on whom now fell the responsibility of their welfare.

THE YOUNG GARDENERS' DOMAIN.

THE DOUBLE WHITE PRIMULA.

FOR yielding a supply of bloom for cutting through the autumn and winter months, this Primula cannot be too highly commended. Our method of cultivation is as follows:—At the commencement of April, old plants which have finished flowering receive a top-dressing of light sandy soil, bringing it well up round the stems. In a short time fresh roots are emitted freely from the base of each; these are then severed from the old plants, and placed singly in 3-inch pots, using a compost of two parts good fibry loam, one of leaf soil, one of well decayed cow manure, and one of silver sand. They are placed in a cold frame, and kept close till the roots take possession of the fresh soil; air is then admitted, and gradually increased as the plants make progress. When well established they are shifted into 5-inch pots, and given the same treatment as before. For the final shift 7-inch pots are employed, and a little crushed charcoal added to the compost. Water must be given judiciously, as an over-supply is fatal to the well-being of the plants. During the month of September the plants are removed to their winter quarters—a low span-roofed house, in which a night temperature of 50° is maintained, and assigned a position close to the glass. In a week or two they commence flowering, and continue to produce spikes of flowers in great abundance till the end of the following February. Whilst flowering a chink for air is left open constantly, and the temperature kept steady by the aid of fire heat.—W. P. S.

THE HORTUS SICCUS, OR HERBARIUM.

NEXT to the pleasure to be derived from growing plants is that which is to be obtained from the collection and preservation of plants for, and in the Hortus Siccus—*anglice*, dry garden or herbarium. As an adjunct or supplementary pursuit to that of gardening it is most useful, for it acts as an incentive to the study of botany, without a knowledge of which we cannot fully comprehend the classification, habit, and uses of plants. From this point of view it is invaluable to us, for it enables us to turn our country rambles to good account in gathering and storing a collection. This is not only desirable from a botanical point of view, but also as forming in all probability a string of reminiscences of places we know and visited in times that are ever being pressed more remotely into the shadow of the past.

Plants intended for the herbarium should be gathered in flower, and

when small. They should be taken with the root. The plants in this state are placed between leaves of paper prepared for the purpose, and between two boards, or under one, from which they are not removed until they have become perfectly flat. When dry change the paper. Some plants, such as Orchids and bulbs, will sometimes vegetate for months in the herbarium after they have been placed there. If plunged in boiling water for a minute, and immediately afterwards placed between paper, their drying will be more rapid. If the plants are unknown or new, indicate their popular names, the altitude at which they were procured, and their habit, also their height, as well as their odour.

In order to be prepared for collecting, provide some sheets of paper of a suitable size (16 inches by 12 is a good size) and several boards of the same proportion. These should be formed of two thin boards glued together, the grain of the one transverse to the other. These may be connected together by means of straps, so as to communicate considerable pressure. A large book of blotting paper between two other similar boards will complete this temporary herbarium.

Insects are the bane of all collections, also of the herbarium, and it requires incessant care in order to preserve the plants and enable them to bear exposure to the air. The following is a good wash—namely, corrosive sublimate two drachms, spirits of wine one pint, in which dissolve a small piece of camphor. This wash should be lightly applied, but so that all the raphides of the flowers and the fleshy parts of the plant are saturated with it.

Beautiful specimens are prepared by an apparatus to which the name of M. Le Coq, Professor of Natural History at Clermont Ferrand, has been given. This apparatus consists of two open covers, made of strong iron wire network, having an iron frame round them, in which the plants are placed between thin blotting paper. After they have been kept under pressure for a few hours the covers are compressed by means of straps, and the open network of the frames allows the moisture to escape freely, while the plants are gradually dried.—C. W. M.

(To be continued.)

A WELL-KEPT GARDEN.

A VISIT to a well-kept garden is both interesting and instructive, and having recently paid a visit to the gardens of Major the Hon. H. C. Legge, Fulmer, Slough, perhaps a brief description of the plants grown there may be acceptable to the young readers of your Journal.

Mr. Mowbray, the head gardener, is well known as a first-class cultivator of Cyclamen, Freesias, Primulas, and Calceolarias; not that the other departments are neglected at the expense of these, as both the fruit and plant houses testify to the good treatment bestowed upon their occupants.

At present the Primulas and Cyclamen, arranged in two span-roofed houses, are making a splendid show, these alone being well worth a visit, and show what can be accomplished by cultural skill. Since my visit Mr. Mowbray has secured the first prize for his Primulas at the Royal Botanic Show. The plants were grown as cool and hardy as possible, all coddling being especially avoided. The healthy and vigorous Calceolarias promise a fine show of bloom in their season. The Freesias, which secured a bronze medal from the Royal Horticultural Society, were over, but it was easy to see what a grand display they had made.

The stove contains fine plants of Crotons, Asparagus plumosus, Dracenas, Caladiums, Anthuriums, Alocasias, and Gardenias, the latter carrying large blooms and very clean foliage. A walk through the fruit houses brought the visit to an end, and I felt well repaid for the journey.—YOUNG PONICA.

PRIMULA CULTURE.

A FEW remarks concerning Primula culture may be acceptable, and as I have in charge a very fine lot of plants it may be useful to other young men, and perhaps a few who are not very young, to know how they were grown. The seeds were sown the first week in March very thinly in large pans. Encouraged by gentle bottom heat plants soon made their appearance. When the first rough leaf was formed they were placed near the glass, and exposed as much as possible to the sun—and it is surprising the amount of direct sunshine they will endure with impunity when accustomed to it from their earliest stages. This exposure results in short, stout petioles, giving the plants a stocky appearance.

The second week in May they were potted singly in large 60's, again placed near the glass, and shaded the first week, then exposed as previously mentioned. The first week in June they were placed in a cold frame attached to the west side of a span-roof greenhouse, and for the first ten days were kept rather close, then gradually hardened, only a light shading of muslin being employed for about two hours during the hottest part of the day—the order was to shade as little as possible. The second week in July they were potted in the flowering size—namely 32's—soon established themselves, and by the fourth week in September they were fine sturdy plants. At this time they were placed in the greenhouse, just sufficient fire heat being afforded to expel superfluous moisture. This treatment soon induced the flower spikes to develop, and for a long time the plants bloomed profusely.

The compost for the intermediate and final pottings was made up of equal parts loam, leaf mould, and old mortar rubbish, with a liberal addition of silver sand. This makes a porous mixture which the Primula apparently delights in.—A YORKSHIREMAN.

[If paper is not very scarce and dear in Yorkshire perhaps a little more may be found another time, so as to allow about twice the space for revision.]

FORCING LILAC.

I SHOULD like to call attention to the Lilac, that delicious pink-and-white flowered shrub which produces such a charming effect in the conservatory early in the year, and affords delightful sprays for cutting. Forcing Lilac is very easy to manage. A number of plants, taken up carefully, and well potted, about Christmas, will if placed in a vinery previously started and duly syringed, commence flowering in a month or little more. After their beauty is over, they should be gradually prepared for planting in the open ground, not be forced again for two years.—IMPROVER.

[This correspondent asks us to "excuse his writing, as it has been neglected of late." Admitted "neglect" is inexcusable. We insert a portion of his communication for the purpose of saying to all whom the remarks may concern, that negligent young men who plead for excuses cannot hope to obtain good positions in the gardening world. This "Improver" has need to improve very considerably, and if he is a man of mettle he will at once commence and pursue diligently a course of self-education.]

FRUIT FORCING.

Cherry House.—Directly the stoning is complete the fruit commences colouring and takes its swelling for ripening. The temperature may now be raised, but it must not exceed 55° to 60° at night, and 65° by day from artificial means, with a little ventilation constantly, increasing it at 70°, and, subject to the "crack" of air at the top of the house, close at that temperature. The heat, however, must not be allowed to exceed that degree in the early part of the day without full ventilation, for ripening Cherries are very liable to crack in a close moist atmosphere. From the commencement of colouring until the trees are cleared of their fruits syringing must cease, or the fruit will split and be spoiled, but a good moisture should be maintained in the house by keeping the surface of the border moistened as it becomes dry, or if the trees are in pots sprinkling the floor two or three times a day, avoiding, however, a stagnant atmosphere. Aphides must be kept under by an insecticide, but fumigation only can be had recourse to after the fruit commences ripening. The border must not lack moisture, and liquid manure should be liberally accorded to trees in pots.

Cucumbers.—Shading may be necessary in the middle of the day for an hour or two in bright weather to prevent flagging, but with the plants healthy and the roots abundant very little will be necessary, always provided they are properly supplied with water and nutrition, and free from eelworm. In case the plants flag without apparent cause examine the roots, and if found at all knotty or swollen in parts apply a solution of soluble phenyle, 1 gill (quarter pint) to 3 gallons of water, giving a similar amount as in an ordinary watering. This will check the eelworm and prove beneficial to the plants as manure. Water plants in houses abundantly, but only when required, keeping plenty of moisture in the atmosphere all day by frequent damping, syringing the plants both ways about 3.30 P.M., closing the house at the same time. To secure tender crisp fruit maintain a night temperature of 65° to 70°, 70° to 75° by day, advancing to 85° or 90° from sun heat, and an increase to 100° will not do any harm after closing. To secure straight fruit employ glass tubes.

In watering plants in pits and frames do it early in the afternoon, so as to get the foliage dry before nightfall. Maintain a good bottom heat by linings renewed as required. Ventilate early and moderately, husbanding the sun heat by early closing, and employ a thick night covering over the lights. Avoid overcrowding, keeping the shoots stopped to one joint beyond the fruit, and remove bad leaves as they appear. Keep young plants near the glass, sow seed for raising plants to occupy frames after forced vegetables or bedding plants are removed. Wireworms are sometimes troublesome, coming in with the turf, and as its grass is dead they are usually ravenous. They cannot resist baits of Carrot, Turnip, Mangold Wurtzel, or Potato cut into thick slices and inserted in the soil a couple of inches, examining the baits every morning. Millipedes and woodlice are equally fond of these vegetables, though woodlice prefer boiled Potato wrapped in a little hay, examining them daily.

Figs.—*Early Forced Trees in Pots.*—Ventilation must be increased when the fruit shows signs of ripening, and exposure to the sun greatly enhances the flavour. Many fruits, however, cannot have full exposure to the sun, but judicious pinching, thinning, and tying the branches admit of their receiving a fair amount, and light, with a free circulation of air and freedom from water, is absolutely essential to well-flavoured Figs. This dryness of the atmosphere greatly encourages the Fig tree's worst enemy—red spider. It does not make much progress under good syringing, but when the atmospheric moisture is reduced its spread is something remarkable, therefore no effort should be spared to have the foliage clean up to ripening time.

Brown scale also spreads rapidly over the young shoots, and extends to the leaves and fruits. There is nothing like contesting the advance of these pests on their first appearance. A little soapy water applied with a sponge to the first specks of red spider on the under side of the leaves,

and the young scale dislocated by a brush dipped in a softsoap solution, 1 oz. to a quart of water, saves much after trouble, but care must be taken not to injure the fruit, which is extremely tender. Supplies of water at the roots are needed through all stages, yet less when the fruit is ripening than during its swelling. Figs for home use should be ripe when taken from the trees, those for sending away must be gathered before they are fully ripe. Increase the ventilation at 70°, affording air constantly during the period of ripening. Day temperature 80° to 85° from sun heat, and night temperature 60° to 65°.

Succession Houses.—Trees in inside borders will need abundant supplies of water, and those in narrow borders and carrying heavy crops of fruit require liquid manure, with rich surface dressings. Attend frequently to tying-in, thinning, and stopping the shoots at about the fifth leaf of such as are required to form spurs, and avoid overcrowding the shoots. Maintain a night temperature, after the leaves become full sized, of 60° to 65°, and 70° by day, allowing a rise to 80° or 85° from sun heat, ventilating from 70°, closing at 80°, so as to rise 5° or 10° afterwards.

Late Houses.—The trees in these require syringing on fine days sufficiently early to allow of their becoming dry before night. Ventilate in the early part of the day. Strive to secure solid growths, and close early in the afternoon with plenty of atmospheric moisture where there is means of excluding frost, but in unheated houses afford moderate moisture only.

Melons.—Secure every ray of light to plants swelling their fruits by keeping the glass clean, and supply water liberally to the roots, or liquid manure, providing plenty of atmospheric moisture. Overcropping not only renders the fruit small but prejudices the quality, which is proportionate to the amount of solidified matter and its transformation in ripening. This is best effected by a somewhat dry and warm atmosphere, with diminished supplies of water at the roots, but there must not be any deficiency until the fruit commences ripening, and not then if the plants are to continue for a second crop. A little air constantly will keep the fruit steadily ripening. During the setting of the fruits a drier condition of the atmosphere and soil is advisable, but the soil must not become so dry as to cause the foliage to flag. Attend daily to setting the flowers, stopping the growths as the flowers are fertilised. Keep the temperature at 65° to 70° at night, 70° to 75° by day artificially, and between 80° and 90° with sun heat, ventilating carefully at all times, avoiding sudden fluctuations in the moisture and of temperature.

Plants in pits and frames are showing fruit, and unless they are sufficiently numerous to insure two to four fruits on a plant setting about the same time, it is advisable to remove the first flowers, as with more shoots there will be no difficulty in securing five or six female blossoms of simultaneous growth on each plant, which should be fertilised. Maintain good linings, bottom heat, and a dry condition of the atmosphere when the fruit is setting. After the fruits are set let them be raised on a flower pot, with a slate intervening, above the foliage. Earth up the plants as they advance in growth, having this effected before the fruit is set, as it cannot well be attended to afterwards in frames. Make new beds and put out plants, sowing, potting, and otherwise preparing for planting successional beds.

Pines.—Young plants in course of preparation for fruiting often become soft, drawn, and weakly in growth through a close, moist atmosphere and high temperature. This should be carefully avoided by dispensing with fire heat as much as possible, relying for robust growth and a sturdy habit on sun heat. Maintain the temperature at 60° to 65° at night, and 70° to 75° by day artificially. This is sufficient to sustain the plants in steady progress. Commence ventilating at 75°, gradually increasing it with the temperature to 85°, keeping it through the day at 85°, 90°, or 95° from sun heat, with abundance of air. Close at 85°, but not so as to greatly raise the temperature, for however beneficial this may be to plants swelling their fruits it causes attenuated growth in young plants. Sprinkle the paths and walls at closing time, and syringe the plants lightly about twice a week. Examine each plant before water is given, and when needed supply sufficient to moisten the soil down to the drainage.

Plants swelling their fruit are assisted by judicious applications of liquid manure, to be withheld when ripening commences. Stake the fruit to keep it in an erect position. When the suckers of fruiting plants become large enough screw out the hearts of those not required for stock; one, or at the most two, should be retained on a plant. The temperature should range in fruiting houses from 70° to 75° at night, and 80° to 95° by day. As the fruit ripens the plants may be removed to a cooler house, and the fruit will then keep sound for a lengthened period, longer, indeed, at this time of year than any other.

THE KITCHEN GARDEN.

Asparagus.—Where the beds were not kept saturated and cold by a heavy covering of manure, shoots have started early and strongly. Hovering straw or strawy litter over these early shoots saves them from spring frosts, which have already done much harm to those unprotected. Not having been dressed with manure a heavy surfacing of either manure or common salt, using enough to whiten the surface, may well be applied after just loosening the ground with a fork. This will act as a manure to the Asparagus and destroy the weeds. Those beds heavily mulched during the winter should have all the more flaky portions of the manure removed, a surfacing of short manure doing good in the direction of keeping down weeds and conserving moisture during the summer. If clayey soil were mulched during the winter and recently cleared of the manure, it will have already run together badly after the

rains, and dressing with salt only aggravates the evil. In all probability it is already rich enough, and in any case a dressing of fish manure, guano, or soot is preferable to salt. Salt to be applied as a last resort against weeds.

Planting Asparagus.—After top growth has commenced is the best time to plant Asparagus roots. The more forward shoots may be 1 foot long when the plants are moved, and fewer failures take place than is the case when transplanting is done before top and root growth has commenced. Avoid any undue exposure of the roots to cold winds and sunshine, the planting being best done in dull showery weather, though not if the ground is in a wet state. A deep, moderately rich, free working soil, and well-drained site suits Asparagus, and under these conditions no extra expense need be incurred in making special preparations. Should the site be somewhat cold and none too well drained, and the soil of a clayey nature, then a free addition of decayed manure, leaf soil, "burn bake" sand, and fine mortar rubbish should be made to the soil, and raised beds also be formed. The larger beds may be from 4 feet to 5 feet wide for three rows of plants, or only 3 feet wide for two rows of plants, with 1 foot or wider alleys between them. Dispose the outer rows of plants not less than 9 inches from the edges, and in all cases from 15 inches to 18 inches apart in the rows, allowing the greater distance on strong ground. Open wide holes with slightly raised centres for each plant, spreading the roots out naturally, and covering with 3 inches of good fine soil. Two-year and three-year-old plants are supplied by nurserymen, but in neither case ought any shoots to be cut the first year, and few, if any, during the second season after planting. Cutting from young plants weakens them seriously, and they are slow in attaining a really serviceable size accordingly. No salt should be applied to newly planted Asparagus, as there is a risk of injury to the broken roots.

Sowing Asparagus Seed.—Now is a good time to sow Asparagus seed. The plants may be either raised where they are to remain, the beds being prepared as advised for plants, or they can be raised on the level, and transplanted in the following season. Open shallow drills, and sow thinly. Nearly every seed will germinate, and if sown thickly much early thinning-out of seedlings will be necessary.

Beet.—It is yet early to sow the main crop of Beet, especially where the roots are liable to become coarse. For an early supply sow a long row, or several short rows, of the Turnip-rooted variety in a warm position. Sow thinly in drills 1 inch deep.

Carrots—For the successional supplies sow a good stump-rooted or Horn variety on a warm border in shallow drills 9 inches apart. The roots obtained in this way ought to be ready for use by the time the crops in frames are exhausted. The main crop may also be sown during the first fortnight in April. Carrots should have a freely worked soil, sandy from choice, requiring no manure if plenty were dug-in for preceding crop of a surface-rooting nature. Nantes Horn and Intermediate keep fairly well, but are not available so late in the season as Altringham and Long Surrey. For the first named the drills may be 9 inches apart, 12 inches sufficing for the rest. Open shallow drills, and lightly dust wood ashes along these as a preventive of maggot. If the seed cling together well mix it with sand, or otherwise it will not be possible to distribute it regularly and thinly.

Chicory, Salsafy, and Scorzonera.—Ground previously occupied by any member of the Brassica family, for which manure was freely dug in, or even by Potatoes, only requires to be deeply dug and got into a finely divided state for either of these three crops. What are desired in the case of Salsafy and Scorzonera are long, straight, quickly grown roots, but if they come into contact with manure forking is liable to take place. Should it be thought advisable, therefore, to apply solid manure let it be dug in deeply. Draw shallow drills 12 inches apart, and avoid thick sowing, especially in the case of the comparatively small seeded Chicory.

Turnips.—To be good these must grow quickly. Most failures occur when hot and dry sites for the rows are chosen. No better position than the freely manured clear spaces between young fruit trees or bushes can be found for Turnips. Sow a pinch of Early Milan, in order that there should be no break in the supply; but Snowball and Veitch's Red Globe, if slower in "bulbing," are by far the best in point of quality. Sow thinly in shallow drills 15 inches apart. In showery weather the seed germinates quickly, and directly the seedlings push through the soil dust them over with soot and lime as a preventive of attack by either birds or flea. Those more advanced to be similarly treated occasionally, and also be lightly thinned out where crowded.

PLANT HOUSES.

Solanums.—Plants that were cut hard back and have broken freely should have half the soil removed from the roots and be placed again in the same size pots. For the present grow them in a vinery at work, and pinch any shoots that are taking the lead. Watch for aphides and destroy them at once if they make their appearance. These plants grow well in loam, sand, and one-seventh of decayed manure.

Primula obconica.—Plants intended to produce seed should be placed where they can enjoy abundance of air when the weather is favourable. Young plants in thumb pots ought to be grown on a moist base where they can be shaded. When exposed to bright sunshine the foliage assumes a sickly hue and the plants become a prey to red spider.

Chrysanthemums.—Early flowering kinds should, if room can be found for them, be placed in the pots in which they are to flower. They must be properly hardened before potting, and then placed carefully

outside where they can be sheltered from rough winds and frost. Plants that have been recently rooted, and are well established in small pots, should be placed into 5-inch without delay. These plants are often run up weakly by keeping them in a close confined atmosphere in their early stages. Cuttings may still be inserted for providing plants for decorative purposes.

Francoas.—These are most useful for furnishing in 5 and 6-inch pots, and for these sizes it is a good plan to raise the plants from seed annually. The smallest plants from last year's seedlings may be potted for another year. The remainder may be divided into two sizes, and brought into flower at different times. If the largest are placed in a temperature of 45° to 50° they will soon produce flower spikes, while the others should be kept cool. Seed may be sown at the present time if this has not already been done.

Carnation Miss Joliffe.—If cuttings of these have been inserted together in pots or pans, pot them singly directly they are rooted; 2½-inch pots will be large enough. As soon as they are established gradually harden the plants to cool treatment. Carnations are soon spoiled if kept in heat. Cuttings of these and tree kinds may still be rooted. Strong plants for flowering under glass should be finally potted.

Amaryllis.—As plants go out of flower place them in a light house, not too warm, where air can be afforded daily to insure sturdy foliage. Growth must be well developed, well ripened, and the plants thoroughly rested, then they will be certain to flower profusely. These plants are so easily raised from seed that if a few good varieties are obtained a stock of seedlings may soon be had, many of which will be equal to named kinds.

Double Primulas.—Plants that have been kept somewhat dry may have the lower leaves removed and the stems covered with light soil. If kept moist after this they will soon emit roots near the collar, when each portion may be taken off and potted. It is a mistake to place the plants in brisk heat to hasten the process of rooting, for this induces damping.

Salvia gesneræflora.—This is a very showy plant for this period of the year; cuttings may still be rooted. If large plants are needed shorten back those which have flowered in 6 or 7-inch pots, and place them in 10-inch, or an even larger size, when they will make specimens 5 or 6 feet high, and fully 3 feet through, almost perfect pyramids, during the season.

THE BEE-KEEPER.

BEST HIVES FOR WINTERING.

In an apiary where there are numerous stocks of bees in hives of various patterns, some of which are single-walled, others double-cased with an air space at the sides, some again packed with chaff or cork dust, the bee-keeper has an opportunity to ascertain which is the best hive for wintering purposes. It may appear strange to those who have not experimented on the above lines to be now told that there is really little difference, taking one season with another, between the different hives above mentioned.

One spring a double-cased hive placed in a south aspect may be found on examination to be extra strong in bees, and otherwise in good condition. The following season a colony wintered in a single-walled hive having a west aspect will be found to be superior to all others. At the present time the strongest stock in my apiary has been wintered in a double-cased hive having an open air space round the sides, and is facing due east.

This is doubtless the experience of other bee-keepers who have paid close attention to their bees. Why such is the case it is difficult to say, for according to theory those bees having a southern aspect, and also having the advantage of a warm corner, should invariably be the best. But that such is not the case I have proved times out of number. Although different hives have been of equal strength in bees, which have been requeened on the same date, the queens being reared from brood taken from a prolific queen, and the colonies afterwards fed up for winter with the same weight of syrup to each, when examined six months afterwards some stocks will be found to have many more bees, and be in a much better condition than the others.

I am inclined to think the cause of this is

LATE BREEDING IN AUTUMN.

If bees have an extra supply of stores in the autumn, and the weather is fine, some queens will continue laying until the end of September or even later. The bees hatched at that season are the workers of early spring, as they will not die off like the old worn out bees.

But should a queen continue laying until late in the autumn, and stores run short, late breeding will not be a success. The young bees will succumb on the first approach of severe weather, and if they should by chance survive the winter they will be found in an unsatisfactory condition the following spring.

Other colonies to which a young queen had been introduced may become weak, owing to the fact that there are no young bees to take the place of the old worn out bees, as very few of the workers hatched at midsummer will be found alive at early spring. Some queens stop laying much earlier than others, and to this fact (all other things being equal) more than any other, I ascribe so much difference in the various stocks at this season.

It is not advisable to encourage the queen to continue laying after the middle of September, and care should always be taken to feed them up for winter (which operation I always carry out as soon after the honey flow is over as possible). Examine all colonies a few weeks afterwards to see that they are provided with sufficient stores to tide over the winter, and any that are short through the above causes should be at once supplied with the necessary stores. This has more to do with the successful wintering of bees than many bee-keepers suppose, even more than any special hive, or the position in which it is placed. This, and having all hives thoroughly waterproof, are the chief factors in connection with the successful wintering of bees.

STRAW SKEPS.

Bees invariably winter well in the old fashioned straw skep, but what has been said about the moveable frame hive is equally true about bees in skeps. The late Mr. Pettigrew was a firm believer in the straw skep, and recommended bee-keepers to use "nothing but straw hives for bees. Hives made of wood at certain seasons of the year condense the moisture arising from the bees, and this condensed moisture rots the combs." Were he living at the present day he would doubtless have altered his opinion of wooden hives, as they are now more common throughout the country than straw skeps, and a much greater weight of honey is obtained annually in consequence. It is better to allow the bees in straw skeps to swarm, as by this means they will be kept in a healthier condition than if supered year after year without the combs being renewed.

There has been a great loss of bees during the past winter among cottagers who keep their bees in straw skeps. It cannot be owing to the severity of the winter, but through the loss of queens at a critical period, when it was impossible to rear others. Owing to the peculiar season few swarms were obtained last year from skeps. The queens in many cases that have come under my notice were three years old, ample stores of honey were in the hives, but they succumbed from old age.

With the moveable frame hive this could have been prevented (as it might have been in skeps), but so few bee-keepers who are contented to keep bees in skeps ever take the trouble to examine them.—AN ENGLISH BEE-KEEPER.

LARGE HIVES.

"AN ENGLISH BEE-KEEPER" (page 281) says, "I agree with 'G. H.' (page 240) when he states that large hives need less attention as to feeding, but he does not say why this is so." I hasten to tell "A. E. B." that I have found hives having capacity for the full laying powers of the queen, and stores for carrying on the work of the hive. I refer to hives having nearly 4000 cubic inches. Such hives keep abreast of the time, and the queen laying from 3000 to 4000 eggs daily the bees have not room for the storage of honey to prevent them entering the supers, as "A. E. B." supposes; but on the contrary, there are more bees to work in the supers. Again, "A. E. B." says, If the hive is larger than is necessary by the time this takes place the honey flow will be quite over, and little surplus will be stored in the supers.

"It must have been a hive similar to the above that 'G. H.' had in mind when he stated in a previous issue that if we want to take as much surplus as 250 lbs and leave 100 for stores we must go in for larger hives." I found I made a slight mistake here. I should have said, "And yet leave 100 lbs. untouched," instead of 100 lbs. for stores. I may honestly tell "A. E. B." it was a hive somewhat like this that my mind was on, and is still on, but not too large, as "A. E. B." supposes. It seems to please my friend to remind me of this grand hive, 250 lbs. taken, 100 lbs. left untouched to be taken when required. I ask my friend if he has done better than this, if he has had 350 lbs. from a hive with ten standard frames without any adding from other stocks? He will perhaps tell us in his next notes. Yet this 350 lbs. is an established fact, and if "A. E. B." will turn back to the Journal of 1894, May 10th (page 374), it will be found recorded.

LARGE HIVES AND SUPERS.

I fail to see the logic of "A. E. B." when he says that bees in large hives will not enter the supers till the honey flow is nearly over. Bees covering twelve frames, 20 by 8½ inches, and it can be done before the honey flow; they will enter the supers quite as soon—yes, in some cases sooner than those on ten standard frames. The reason of this is not far to seek. In the former more bees are hatched than in the latter, hence stronger hives. We find no difficulty in this locality in getting our bees into the supers of large hives; 100 lbs. have been taken here at one time from a hive with twelve 20-inch frames, and more left in the hive.

Moreover, these hives are no new creation; I think they would be in use before the hives that take ten standard frames. If "A. E. B." will turn back again to June 7th, 1894 (page 462), he will find Mr. Cowie in Scotland with hives with fifteen frames, 20 inches by 8½ inches inside measure, and two tiers of supers filled. If this can be done by the 7th of June, surely bees in large hives will enter the super before the honey flow closes. Hives like the above at the same date would gladden the heart of "G. H.," and no doubt the heart of "A. E. B." too.

EARLY DRONES.

In a previous issue I spoke of a hive containing twelve frames, 18 by 8½ inches inside measure, covering nine frames, with drones in the hive. What "A. E. B." says about early drones in hives holds good in some cases, but not in the one in question. The hive has a vigorous queen, plenty of hatching brood, and in every way prosperous. I should think by the end of April or the first week in May will crowd the hive.—GEORGE HOWDENSHERE.

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," S. Rose Hill Road, Wandsworth, London, S.W. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Brisbane Lily (W. G. W.).—Eurycles Cunninghami is a native of Queensland, and a white-flowered bulbous plant, growing about 1 foot in height. It requires a warm greenhouse or cool stove. The bulbs may be grown singly or three in a pot, in a compost of two parts good turfy loam, one part peat, and one part decayed leaf soil or cow manure, adding one-sixth of sharp silver sand. The plants should be grown in a light position, watering carefully at first, but freely when growing. After growth is completed water should be withheld for a few weeks, so that the bulbs may ripen and rest. The withholding of water, however, must be partial, not allowing the foliage to suddenly flag and go off, as flowering depends on the maturity of the growth. It is an excellent practice to place the plants in a frame or pit from the end of June until the middle of September. When established the less frequently the plants are repotted the better, provided they remain healthy. When a shift is necessary all the living roots should be carefully preserved, and any dead ones cut away. After the plants have once started, their growth cannot well be too rapid, nor the supply of food too liberal. Small bulbs will under proper culture make good flowering plants in the course of two or three years. The main points are to afford to them plenty of light, with abundant nourishment when making and perfecting growth, careful ripening, and then rest.

Small Insects Eating off Seedling Begonias (J. G.).—The minute creatures on the stamp margin paper are a species of spring-tail (Thysanura), but not a "jumper" named Lipura fimetaria, Linn., which browses upon various tender vegetables, and is common amongst leaf mould and other decaying matter. The remedy you have used—a little weak Fir-tree oil lukewarm—is very effective against them, and acts deterrently of their attacks. The flies have probably issued from pupæ in the soil; indeed, you have sent a pupa case from which one of such flies has emerged recently. It is the Cabbage fly, Anthomyia brassicae, Bouché, which does much harm to cruciferous plants at the roots by its larvæ or maggots, as you are no doubt well aware. The flies do no harm whatever only by being the parents of the maggots, which are not likely to be found at this time of year, even if they at any time attack Begonias. You seem to have overlooked the mycelial threads of a fungus when examining the soil with a "glass." They, however, are present along with the "small insects," and it is Botrytis vulgaris, which often sweeps off whole pot or pans of seedlings, being developed from a sclerotium, which you have also been kind enough to send, and appear to have overlooked. For this there is nothing better than sterilisation of the soil before sowing the seed by soaking with boiling water, allowing the soil to become in suitable condition for the seed before sowing.

Conservatory at Grove Park (T. Street).—A letter posted to the address you gave has been returned by the postal authorities marked "not known." Can you offer any explanation?

Calceolaria Requirements (S. E. H.).—The shrubby or bedding Calceolarias require an open situation, as they must have plenty of light to insure a sturdy and free-flowering habit. The site, however, must not be hot and dry, as the plants delight in moisture, which of course can be secured by mulching with short unobjectionable material, or cocoa-nut fibre refuse, and supplying water in droughty weather, but not over the flowers, as these are soon injured by wet. Shelter is also necessary, the force of winds doing injury to the somewhat brittle plants.

Tomato Leaf-ribs Rusted (Tomatoes).—Beyond the "rust" on the midribs we failed to find anything amiss with the leaves. We examined them in every possible way, but did not discover any fungus or other body likely to cause the rust, which is purely mineral matter, or extravasated sap oxidised. Thus the cells have been disorganised or ruptured, and the rust appears, followed by the leaves curling as growth has ceased at that part. What is the cause of extravasation remains unexplained, but it usually arises through a sudden check to growth, followed by a rush of sap and exudation of matter. It is common on Potatoes in fields, and not much less so on Tomatoes under glass in certain seasons; seldom being attended by any serious consequences to the plants, though disfiguring them. Indeed, it often means great fertility and high-class produce. The white matter appears to be lime, which requires for its utilisation a corresponding amount of potash; therefore, we should employ a dressing of bone superphosphate, three parts or pounds, nitrate of potash (crushed) two parts or pounds, and kainit one part or pound, mixed, using 2 to 4 czs. per square yard, watering in moderately, and employing at intervals of about three weeks. We have found this useful under similar circumstances, the thing being not to apply it excessively so as to injure the roots or induce too luxuriant growth. It is a good all-round plant food, and has a tendency to fortify the plant against its fungoid enemies.

Epiphyllum Failing (M. F.).—It is a great pleasure to us to assist amateurs as well as gardeners whenever we can do so, and no one need hesitate to ask for information on any gardening subject at any time. When Epiphyllums get old they are prone to fail by canker near the soil, especially when raised from cuttings, but less so when established by grafting on the Pereskia stock. It may be your old plant is irrecoverable. If the stem is cankered the supply of nutriment would be arrested, shrivelling of the growths following as a natural consequence. They would shrivel also if the soil was by accident allowed to become either too dry, and long remain so, or too wet, as in one case the roots would perish by shrivelling and the other by decaying. Carefully examine the soil, and if it is very dry and shrinking from the pot sink this over the rim in a pail of warm water for three hours. If, on the other hand, the soil is very wet and pasty, it is probably sour. In this case turn the plant out of the pot, and with a pointed stick remove as much of the sour soil as will liberate many of the roots; then place in a smaller, clean, well-drained pot, using a mixture of six parts loam and one part each of powdered charcoal and old dry mortar. Protect the drainage with moss or fibre, and place in sufficient soil, which, when pressed down rather firmly, but not made hard, will raise the collar of the plant on a level with the rim of the pot; then work in the fresh compost among the roots, adding a little at a time, so that they may be evenly distributed through it, pressing down as before, and making level half an inch or more below the top of the pot. The soil must not be either decidedly wet or dry when used, but moist enough for compression. Pick out some of the old soil from the stem, and place round it a little crushed mortar rubbish and charcoal. Do not stand the plant in the sun nor give water at once, but prevent evaporation from the stems by spraying them occasionally through a vapourising appliance, placing the end in a phial and the blow-tube in the mouth. In three or four days time give enough tepid water to pass quite to the drainage, then wait till the soil crumbles when rubbed before giving more in the same way. Mere surface sprinklings, giving "just a little" water frequently, are worse than delusive—namely, dangerous in conducing to the canker of the stems. You are at a disadvantage in not having proper convenience for Epiphyllums. If you can induce the sickly plant to make fresh roots and keep them growing, through good judgment in watering, the stems will freshen; if you cannot obtain active roots we fear the plant must die. We have done all we can to help you to save it. If it should collapse you must try and derive consolation in the same way as a gentleman once did who had two cherished plants (not Epiphyllums). They were said to be the only two in Europe, and were valued at £200 each. They were taken to a continental show, at which one of them suddenly died. On our sympathising with the owner on the great loss incurred by the fatality, he took the matter philosophically and said, "I am sorry to lose the plant, of course, very sorry, but it simply doubles the value of the other; its price was £200 yesterday, it is £400 to-day." The gentleman is living, and will not forget the circumstance. Returning to the Epiphyllums, when summer comes to stay, not before, if the sickly plant recover, stand both in the open close to the south side of a wall or building, sinking the pots in others still larger to prevent the sun injuring the roots, also take care that they are not allowed to suffer by lack of water; syringe the plants daily in hot dry weather, gradually reduce the water supply towards the autumn, then place them in a light position, and keep the soil dry rather than wet during the winter months. Frost is fatal to Epiphyllums.

Spiræas Failing (M. R.).—We sympathise with you in your failure, which is rather a prevalent one this season with late plants, and said to have been caused by blight. We, however, have examined several specimens, and not found any animal or vegetable organism on them or in their tissues. A large grower attributes it to the roots being lifted too early in the autumn, the crowns not being sufficiently matured, but another cultivator found the earliest, second, and third batches of forced plants do well, whilst the fourth batch, all of the stock, potted at the same time and treated similarly, alone have failed. This makes the subject very tantalising and unsatisfactory, yet we still consider the plants have been brought forward too rapidly, and that has caused the flowering panicles to become "deaf."

Insect on Plants (S. E. H.).—The insects belong to the order Hemiptera, sub-order Heteroptera, and tribe Lygeidæ, which are characterised by having a small scutellum, four-jointed antennæ, and rather elongated bodies. The species you forwarded is the "Soldier and Sailor," *Astemma aptera*. It is red and black in colour (sometimes slatey grey, with red patches), and found during summer running about in fields and gardens, especially among stones and rubbish. They also are found on plants, and probably visit them to suck the juices, the insect having a somewhat long proboscis withdrawn under the body when not in use. The injury is done by the insect piercing the plant, and causing the sap to flow out. We have not, however, noticed that it does much harm to plants. Syringing the Roses with an insecticide would make the foliage and shoots distasteful to them, and do good in respect of other insects.

Gloriosa superba (W., Reading).—This very ornamental liliaceous plant flowers towards the end of summer, its deep orange and red flowers being very effective. It grows about 6 feet in height, and requires supporting, the leaves having tendril-like apices. The flower petals turn upwards, narrow, deeply undulate, and crispate. Good drainage is always essential, and an open soil, composed of turfy loam and fibrous peat in about equal proportions, with a free admixture of sharp silver sand. The bulbs should be carefully repotted in the early spring, preferably in February, and started in a temperature of about 70°; and, if convenient, gentle bottom heat. Water must be given carefully at first, and during the summer plenty of heat and moisture are necessary, yet always being careful not to overwater. A greenhouse is too cold for the plants. As the growth ripens water should be gradually withheld. During winter the soil must be kept quite dry, and the pots laid on their sides in a dry place. The plant is a native of tropical Asia and Africa, cool treatment, therefore, in the resting season must be specially avoided; indeed, the season of growth and complete rest in a warm place are important considerations in its culture. It requires a stove or, better, a Cucumber or Melon house, where ventilation is practised—not the modern, stew-pan, system of Cucumber growing. The plant is somewhat slow growing, and impatient of root disturbance on account of the brittleness of the bulb, yet should be potted once a year, offsets being taken off very carefully when starting the bulbs, as they are easily injured at other times.

Christmas Roses (A. L. K.).—We have raised many seedlings of *Helleborus niger* by sowing the seeds as soon as ripe and later. When sown within a day or two of the time of gathering many of them have germinated the same season, but those sown later not till the following year. We sow in earthenware pans of sandy loam and leaf soil, covering lightly, but completely, with some of the same sifted. A thorough watering is given through a fine-rosed can, and a few hours afterwards the seeds are sown. The pans are closely covered with glass, and plunged to their rims in damp ashes in a frame on the north of a wall. This is for the purpose of securing uniform moisture in the soil, and avoiding the necessity for frequent surface sprinklings. When the seedlings are large enough they are transplanted an inch or two apart in boxes, these being kept in a frame for a time in the same shaded position, and the plants watered as needed, always before the soil becomes decidedly dry. When the plants are fairly growing the sashes are withdrawn, as the plants derive benefit from the night dews, though when quite young are better if sheltered from drenching rains. When they grow and touch each other in the boxes they are planted 1 foot asunder in the open in deeply worked, free, generous soil, choosing a site where the plants are as far as possible shaded from the midday sun. After the end of the second season's growth a few flowers appear. When they become fairly numerous low posts are driven down, and rails attached to them along the sides of the border for the purpose of supporting sashes for keeping the flowers clean. Failing a sufficiency of these we have protected them with canvas during drenching rains. When the plants cover the ground every alternate one is removed, soil and manure being placed between those which remain, and they gradually form large clusters of crowns, and produce masses of flowers. The plants removed are inserted in deep rich soil in open spaces between fruit trees, or where they can be shielded from the scorching sun. The fleshy roots are placed well down, not spread out near the surface, which is covered with manure, alike for enriching purposes and reducing evaporation. Large individual clumps are worthy of protection by hand-lights or cloches when flowering commences. In deep rich soil and partial shade the clumps may remain undisturbed for years. Christmas Roses are grown by the acre between the lines of trees in cultivated fruit plantations in the Thames valley. They are also grown in the open where the ground is rich and deep, also moist in summer. When old plants are divided this is done when flowering ceases. Seedlings may be raised in free soil, and a shaded position in the open. We shall be obliged by occasional notes as you suggest, written on one side of the paper only, for publication.

Hippeastrums (Amateur).—The best evidence as to the efficacy or otherwise of any particular product is that which results from practical experience. It is impossible for *Hippeastrums* to grow satisfactorily and flower freely if the roots are not in a healthy state. The most successful cultivators of these plants grow them in a compost of two-thirds good fibrous loam and one-third of decayed friable cow manure, with a little leaf soil and silver sand, the whole mixed for some weeks prior to use. The bulbs are kept dry through the winter in the pots in which they grew in the summer. Early in the year the old soil is shaken from the bulbs, and any decayed matter removed from them. They are then placed in pots not more than 2 inches wider than the diameter of the bulbs, using the compost named, which is pressed down firmly. The pots are plunged to their rims in old tan or leaf mould, and if in gentle bottom heat all the better. The plunging material prevents the soil drying, and precludes the necessity for watering till the flower stems are 2 or 3 inches high and leaves pushing strongly. Then the supply of water is increased more and more with advancing growth, and the pots are crowded with healthy roots. Plants thus treated are now flowering magnificently. Overwatering before the roots are active and growth free is extremely prejudicial.

Mushroom Spawn (H. T.).—What is commonly called Mushroom "spawn," as represented by silky looking threads, which interlace masses of manure, is really the plant of the fungus *Agaricus campestris*, the Mushroom itself being the fruiting form of the plant, as producing conidia or spores. When these are mature and fall on a medium suitable alike in constituents, moisture, and temperature, they produce white filamentous growths, which spread in all directions that favour their extension till they produce a cobweb-like mass. This is the mycelium (spawn) or plant of the Mushroom. Eventually in a favourable medium the growth thickens and produces tubercles, which develop into Mushrooms. The first growth direct from the spores, which resembles a cottony mass, through the ramifications of the mycelium, is known as "virgin spawn," and is in great demand by makers of "spawn bricks," because of its strength. The bricks impregnated and filled with this virgin spawn are not sold, but retained for propagating purposes—that is, portions of them are inserted in other "bricks" made from manure and loam, shaped in moulds when the mass is sufficiently dry, but not too dry, for the purpose. These impregnated bricks are packed on their edges, but without the faces touching, forming a floor; then others are similarly placed on them in an opposite direction; and so on till the pile is completed. The whole is then covered with sweet fermenting manure of sufficient thickness to maintain a genial warmth of about 70°. The mycelium then spreads, or the "spawn runs," and in a few weeks the bricks are completely permeated. The covering is then gradually removed, and the bricks dried and stored for use or sale. These are called "first removes," or, in other words, the first obtainable after impregnation with virgin spawn, and are the best that can be purchased. If some of these are used for producing others, these are "second removes" (not so strong, but good), and if these are again used for propagation we have "thirds" (less strong), and so on; the further from the spores the weaker the spawn, or plant, and consequently the "fruits" of it, if any—the Mushrooms. It is not so much a question of the hardness or softness of the bricks as the strength of the spawn that invests them with value. Those you had which answered so well were probably "first removes," and as a good price would have to be given for them, a good price would have to be charged; but the spawn would not be "dear" all the same, because of the abundant produce resulting. Very few retail vendors of Mushroom spawn make their own, any more than builders make their own bricks. It is professional work, and cannot well be learned without practical guidance. You may find more on the subject in "Mushrooms for the Million," and see an illustration of the germination of the spores by the eminent artist and fungologist, Mr. Worthington G. Smith.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, at being often difficult to separate them when the paper is damp. (C. H.).—1, Specimen insufficient; 2, *Pteris cretica albo-lineata*; 3, *Lygodium scandens*; 4, *Adiantum assimile*; 5, *A. pubescens*; 6, a poor specimen, possibly *A. macrophyllum*. (H. S.).—The small flower is *Maxillaria picta*; the large flower was dead. (C. P. C.).—1, *Cupressus Lawsoniana erecta viridis*; 2, *C. macrocarpa*; 3, unknown; 4, *Abies Douglasi*. (E. D.).—*Dendrobium fimbriatum oculatum*. (P. P.).—1, *Daphne Mezereum album*; 2, *Primula rosea*; 3, *Saxifraga Boydii*; 4, *Streptosolen Jamesoni*; 5, *Celsia Arcturus*. (S. R. S.).—1, *Athyrium filix-foemina orbiculare*; 2, *Polypodium verrucosum*; 3, *Cibotium princeps*; 4, *Polygala Dalmaisiensis*. (Somerset).—The two Conifers are not synonyms in Veitch's "Coniferae" and other works. 1, *Pinus Bolanderi*; 2, *P. contorta*.

NOTICE TO NURSERYMEN, SEEDSMEN AND FLORISTS.—G. H. Richards requests us to announce that he has removed his offices from Old Shot Tower Wharf to 124, Southwark Street, S.E. (and this is the address for all letters and orders in future), where he has taken a large warehouse for the manufacture and storage of the light goods connected with his horticultural sundries business. The warehouses at Old Shot Tower Wharf (five minutes distant) being retained for the storage of peat, manures, and heavy goods generally.

NOTES BY THE WAY.

In taking up the "Agricultural Gazette" of March 29th we found one or two things of more than ordinary interest to us, and we shall here reproduce them for the benefit of those who have not had the opportunity of seeing the above-named paper.

There has been much said on the subject of cheap carriage of agricultural produce, a more direct method by which to bring the consumer into nearer touch with the producer, and so far the great obstacle has been expense of transit.

Now the Great Eastern Railway took the matter in hand last year, and issued their list of prices, which was fair and reasonable. The goods were conveyed to purchasers in London, and during the year 1896 60,000 such parcels or boxes had been carried. This year is but in its first quarter, yet the months of January and

February show a total of 12,664 parcels as against 2994 for the same months in 1896. It has been estimated that the average value of each lot would be at least 7s., and the Chairman and Directors contemplate extending the system to other large towns and watering places.

That must be a boon indeed, for who but knows the exceeding dearness of fresh country produce in a fashionable seaside resort. The great towns, too, should prove a ready market, for, as a rule, it is easier to get whatever one wants more cheaply in London than in any provincial town.

The Manchester, Sheffield, and Lincolnshire Railway Company has made a similar departure, and is advertising a list of country people willing and ready to provide their town customers with dainties and pleasant country living. We think the scheme must "go," as this line "taps" such an intensely rural neighbourhood from the Humber to Sheffield in a straight line, and there are the other offshoots quite as remote from the busy haunts of men.

We turn the leaf and find an article headed "Fruit Growing on Farms," by Mr. Cecil H. Hooper. This is a question to which there are several sides. It is no use growing fruit unless we can get it to the consumer quickly, and without the intervention of salesmen's commissions. The population is vastly increasing in the large towns, and the love for fruit is greatly on the increase. For instance, take the Tomato, a few years ago a fruit only eaten by the upper and middle classes. Now go into any market, and ask who are the principal consumers, inquire what becomes of boxes and boxes that arrive weekly in the villages of the ironstone districts. You will find the horny-handed son of toil eats them at every meal, and in prodigious quantities. Give him the chance of other good wholesome fruit, and you will find him an excellent customer.

We think when all the railway companies grant equal facilities to the Great Eastern the thing will soon be an established fact. There are many physicians who strongly recommend that one meal a day should consist entirely of fruit, and no one with a knowledge of children will fail to see how popular such a departure would be in large families, mainly made up of young folks.

Mr. Hooper has a word of warning as to the *where* and *how* of planting. As to soil, he says any land worth cultivating at all will generally do for fruit, provided it is naturally or artificially drained. Damp valleys are undesirable, on account of the worse effect of frost than on higher ground. Apples do best on sandstone; Pears, Plums, Cherries where there is plenty of lime; Raspberries on a light soil full of vegetable matter, and Black Currants on moist land. Observers will soon ascertain for themselves what varieties do best in their immediate neighbourhood.

Then arises the question of a tenant's security. You don't plant fruit trees for nothing, and you therefore must not be at the mercy of a six-months notice. The Agricultural Holdings Act won't help a tenant to get compensation unless he had the landlord's consent to planting in writing. The Market Gardeners' Compensation Act is good security, but it only applies to land recognised as market gardens.

In case of a lease it ought to be transferable; and, secondly, there should be some arrangement as to compensation at the end of the lease, unless the rent has been exceedingly low. In the Evesham district much fruit is grown, and the tenants there have a fairly good arrangement. "The tenant hires the land for a term of years, and if he desires to quit he finds a customer for his interest in the holding and takes him to the landlord or agent, who accepts him as the new tenant if he is considered satisfactory." Mr. Hooper thinks more suburban and provincial markets are required.

We turn to another page, and find a review on "The Wasted Orchards of England." We fear the reproof is needed. The writer bestows little praise and much blame, and the question is on whom is the blame to fall, owner or occupier? Is this a result of the depression in agriculture, or the result of apathy or ignorance? A little of both, probably; but it is ill work appealing to deaf ears.

At Oxford there is a Sibthorpean Professor of Rural Economy, and we note with pleasure that the Clothworkers' Company, London, have offered to guarantee a sum of £200 per annum for five years to enable this Professor (Warrington) to supplement his lectures by others embracing the more important parts of agriculture and forestry, subject, of course, to conditions submitted to the University authorities.

This excellent offer is supplemented by another offer of £100 per annum from a lady whose name is well known in all agricultural circles. We refer to Miss Ormerod. Her reason is this: From her knowledge, gained by much correspondence, she is sure that our great landholders would be much benefited if they were more conversant with the broad principles of agricultural and fruit management, which those in their high positions can hardly acquire except at our leading universities.

Yes, indeed, this practical knowledge would be far above any classical or mathematical training in helping a man to make the best of his ancestral acres.

WORK ON THE HOME FARM.

We have had a fine week and no hindrance to work on the land, which has dried very much, and on light soils Barley has been drilled under very favourable conditions. Any fields inclined to strength are rough and require a good rain to soften the dried clots which the roller has failed to crush.

With drier conditions the weather has been much colder, with considerable frost and occasional show showers. Wheat has stood well, but, alas! for the stocked pastures. From spring-like greenness they have rapidly changed to a brown bareness; the sheep have destroyed with their feet more food than they have eaten; in fact, on a frosty morning a sheep has five mouths. Now we see the full value of the Mangold crop.

After drawing on the Mangold pie for the lambing ewes since March the 1st, and for the cattle for a fortnight, we have been carting away the residue and re-storing them where most likely to be wanted. We have eighty big loads left, and there were only 4 acres of them; except Cabbage we think Mangold the most valuable crop on a mixed farm. It requires liberal manuring, but not too much farmyard muck, or if the season be dry there might be danger of not getting a plant. Three cwt. bonemeal, 3 cwt. superphosphate, and 1 cwt. of nitrate of soda, put in with the seed, with 1 cwt. more nitrate given as a top-dressing after cleaning, would grow an acre of good Mangold on any land not too light for the crop.

It is now time to sow field Carrots. For market purposes, scarlet Intermediate and Altrincham are the best, and the latter is bad to beat for feeding purposes. Deep sandy soil, not too rich, is the best for Carrots. They should be drilled 20 inches apart, and for market purposes should not be thinned. About 8 lbs. per acre is the suitable quantity of seed to sow.

Very little spring corn is up in many places. What is up will soon want rolling, and the small seeds sown, if they were not put in with the corn. The land cannot be too solid for Clover, there is always a good plant on a headland or in a gateway.

The cold weather is keeping the cattle too long in the yards, and they are eating up what we had been hoping to keep in reserve to commence next winter with. We are referring to straw and hay.

REMARKS.

- 4th.—Bright early, and frequent sunshine during day.
 5th.—Sunny morning; generally cloudy after 3 P.M.
 6th.—Fair, but sunless.
 7th.—Heavy rain from 5.45 A.M. to 7.15 A.M.; dull and damp, with fog, till 10.30 A.M.; then occasional sunshine, and thunderstorm from 3 P.M. to 3.45 P.M., and rain till 6 P.M.
 8th.—Fine, and generally sunny after 10 A.M.
 9th.—Cloudy morning; sunny afternoon; rainy evening.
 10th.—Showers early; frequently sunny after 9 A.M.
 An average week, but sharp grass frosts on three nights.—G. J. SYMONS.

OWING to the large increase in their business Smith's Advertising Agency of 132, Fleet Street, have just added new offices at 82, Fleet Street, thus doubling their already large establishment. The new branch will be exclusively employed in transacting advertisements for the provincial papers, the head office retaining all the London work.

**FINEST SELECTED STRAINS
OF TESTED GROWTH**

BARR'S "LIGHTNING" RUNNER BEAN
A valuable acquisition, bearing in abundance clusters of pods, remarkably early, and of delicate flavour. Per Half Pint, 2/-.

BARR'S MONSTROUS LONG-PODDED BROAD BEAN.
The earliest, largest, and most productive of long-podded Broad Beans, and of fine delicate flavour. Per Quart, 2/6; per Pint, 1/6.

BARR'S "LEMON GLOBE" ONION.
A grand exhibition Onion, handsome in form, of large size, mild in flavour, and a good keeper. Per Packet, 1/-; per Ounce, 2/6.

FLOWER SEEDS.—Barr's Specialities for 1897.

NEW LARGE-FLOWERED CRESTED BEGONIA.
A splendid novelty, the large handsome flowers having crested combs, colours brilliant and varied. Per Packet, 3/6 and 5/-

BARR'S SUPERB FRINGED PETUNIAS.
Flowers of immense size and deeply fringed, colours rich and varied. Per Pkt., 2/6 & 3/6.

BARR'S Extra Selected LONG-SPURRED COLUMBINES.
Mixed, flowers of great beauty in form and colour. Per Packet, 2/6.

BARR'S NEW SEED GUIDE FOR 1897
will be sent free on application.

BARR & SONS, 12 & 13 KING STREET, LONDON.
Nurseries at LONG DITTON, Surrey, near to Surbiton Stn., S.W.R.

BEGONIAS.

Double and Single, Gold Medal Collection, for Conservatory and Exhibition, the largest and best in the trade. See Catalogue.
BEGONIAS FOR BEDDING, superb quality, Double, 6s. and 9s. per dozen; Single, to colour, 5s. per dozen, 35s. per 100; 10 colours mixed, 4s. and 28s.; fine mixed, 3s. and 2s.

B. R. DAVIS, YEovil, YEovil, SOMERSET.

LILIUM AURATUM.

The beautiful golden-rayed Lily of Japan. Magnificent for pots in the greenhouse, or for growing in the open garden. Deliciously scented, quite hardy. Planted now will bloom splendidly during the summer and autumn. Extra fine roots, 10 to 11 inches circumference, per doz., 7s. 6d.; 6 for 4s.; or 25 for 14s. Grand selected roots, 11 to 13 inches circumference, per doz., 12s.; 6 for 6s. 6d.; or 25 for 21s. All post or carriage free for cash with order.

DANIELS BROS., Town Close Nurseries, NORWICH.

CARNATIONS.—Clearance Sale.

A grand collection of choice named double flowered, in beautiful variety, including all the finest sorts. Strong plants from single pots, correctly named, per doz., 4s. 6d.; six for 2s. 6d.; or 25 for 8s. Double crimson Clove, deliciously scented, per doz., 3s. 6d.; six for 2s.; or 25 for 6s. 6d. Packing and carriage free for cash with order.

DANIELS BROS., Town Close Nurseries, NORWICH.

CHRYSANTHEMUMS.

CLEARANCE SALE.

A splendid collection, including all the most beautiful and popular of the Japanese and incurved varieties; strong, well-rooted cuttings, correctly named, per doz., 1s. 6d.; per 100, 10s. 6d. Extra choice sorts, per doz., 2s. 6d.; per 100, 15s. Six grand new exhibition varieties splendid, the set 3s. 6d. All post free.

DANIELS BROS., Town Close Nurseries, NORWICH.

FUCHSIAS.—Clearance Sale.

A magnificent collection of superb double and single flowered varieties, including the newest and most beautiful sorts in cultivation. Splendid for pot culture or the garden. Strong young plants, from single pots, correctly named, per doz., 2s. 6d.; six for 1s. 6d.; or 25 for 4s. 6d. Extra choice sorts, per doz., 3s. 6d.; six for 2s.; or 25 for 6s. 6d., post free.

DANIELS BROS., Town Close Nurseries, NORWICH.

20 ACRES of FRUIT TREES

In all the best sorts and forms for the Villa Garden or the Orchard. Free from blight and disease, clean, healthy stems, and branches carefully pruned in good form. Roots a mass of fibre. Sizes from maidens to trees six to eight years old of many kinds, and all TRUE TO NAME.
NEW CATALOGUE, with descriptions and Prices, Post Free.

CLIBRAN & SON,
MANCHESTER, Bangor, Llandudno Junction, and Oldfield Nursery, ALTRINCHAM.

THURSDAY, APRIL 22, 1897.

DRILL HALL DIFFICULTIES.

FOR a considerable time it has been apparent that the Westminster Drill Hall has become inadequate for the proper accommodation of the products displayed at many of the meetings. The tables have been simply packed with exhibits of various kinds, not all of them of specially superior merit or rarity. It has also been observed that unexpected consignments have arrived for which space could not in the nature of things be reserved, this involving either shifting or crushing together the earlier arrivals, or rejecting those of which either notice had not been given or the extent of space required granted. In fact, an unsystematic method of procedure had almost come to be established such as could not be permitted at well-managed shows.

While it is gratifying to see the active and ever-widening interest taken in plants, flowers, and other products of the garden, as represented by not only the pressure of exhibits but by the increasing number of visitors to admire them, and while the enterprise of the several purveyors of what is beautiful and good is entirely commendable, still when exhibiting is conducted on what may be termed haphazard lines, grave inconvenience is bound to ensue sooner or later. It is to be conceived that it has already been felt, and besides, the absence of precise rules and loyal adherence to them cannot possibly be conducive to the harmony of feeling that should prevail on the occasion of the periodical meetings.

It cannot be seriously asserted by impartial visitors that of late the Committee meetings of the Royal Horticultural Society have been in anything like strict accordance with the purpose and object for which these meetings were established—namely, the presentation of new or rare plants, flowers, or fruits at times when they could not otherwise be brought before the public for examination by persons specially qualified to appraise their value and determine the honours to which they might be entitled. That is and always has been the primary object of the periodical assemblages, plus collections of products embodying distinct or special features investing them with more than ordinary interest

because of their beauty, usefulness, or the cultural skill displayed in their production.

All who habitually attend the Drill Hall meetings, and know what is good when they see it, will most readily concede that time after time collections of fruits and vegetables, also groups of plants and flowers, have been in the highest degree meritorious. They have represented cultural skill of the first order, and have been in truth grand object lessons, inciting to greater efforts on the part of many persons who have been impressed with what they have witnessed.

On such imposing and instructive displays have been bestowed well merited honours; but the same strict adherence to the facts of the case have compelled both adjudicators and on-lookers to admit that by no means all the contributions have been of a particularly commanding nature. Some collections have been composed of plants or products of the most ordinary kind as if to suggest that the exhibitors felt compelled to "show something;" and further, the exhibits have suggested that if the individual items were of a commonplace nature that even these would "tell" if the bulk were of unusual proportions.

Again, it has often been observed and remarked that in the desire to make a "great display" exhibitors have not infrequently overshot the mark by including so many inferior samples, and these of necessity lowering the average value of the whole. It is quite certain that if one-third, or occasionally one-half, of the relatively inferior products had been withdrawn that the superiority of the remainder would have had greater weight, and the merits of the exhibit in its entirety raised accordingly.

It is true, as has more than once or twice or thrice been heard, that the adjudicators have sometimes seemed to encourage collections by granting awards more because the exhibits have covered a great extent of table space than anything else, and it has been said that kind and generously disposed men are prone to let their hearts rather than their heads dictate the voting of medals, because a showman has "been at such great trouble and expense to bring so much stuff." The governing body of the Society cannot prevent a body of twenty or thirty men voting medals at times on the principle of generous impulse; and the greater the number of adjudicators jostling against each other the greater is the reduction of individual responsibility; but the Council can limit the extent of collections, and this would have a tendency to increase their intrinsic value, and a hall less crowded with products, with every item good, would be more worthy as a spectacle in horticulture than a crush and a jumble.

Moreover, if it be desired, as seems to be the case, and not unnaturally, to limit the awards of medals to a matter of cold-hearted justice the Council can do another thing—namely, instruct the Committees to delegate three (as in the case of judging fruits for flavour), or not more than five members to examine the collections and recommend awards for them. Each member would then be impressed with a sense of his individual responsibility, and the various points could be much better discussed than by a score of men in a hurry. There would always be plenty of members to deal with the produce at the tables.

These remarks have been incited by a circular we have received from the Royal Horticultural Society bearing on the overcrowding of the Drill Hall, and the sending of large consignments on the assumption that space can be found for them whether the hall is full or not.

EXHIBITORS AT THE DRILL HALL MEETINGS.

The Council of the R.H.S. wish to remind exhibitors that the object for which the various Committees of the Society were constituted and the bi-monthly meetings held was to allow of any new or rare flower or fruit, which might be in perfection at a time when no exhibition was being held, being submitted to a body of experts for adjudication.

By degrees a practice has grown up of groups of plants and collections of fruits being also sent by exhibitors, such plants and fruits being frequently neither new nor rare, and these groups and

collections have become so large and frequently so numerous that there is danger of the more important work of the Committees being lost sight of.

The Council, whilst grateful for the consistent support the Society has received from exhibitors, and desirous of offering every encouragement to them, and of seeing the Drill Hall always well filled, feel that the time has arrived when some limit must be put to the size of the groups and collections; they have therefore drawn up the following rules, which they have directed the Superintendent to strictly adhere to:—

1, Exhibitors at the Drill Hall of groups and collections must give notice to the Secretary, R.H.S., 117, Victoria Street, Westminster, not later than the Friday before, of their desire to exhibit, and must, at the same time, state the nature of their proposed exhibit, and how much space it will occupy; this must in no case exceed 100 square feet.

2, Exhibits entered separately for the separate committees will be considered distinct, but not more than 100 square feet of table space can be allowed for each; that is to say, an exhibitor may stage 100 feet of fruit, 100 feet of Orchids, and 100 feet of Floral Committee plants and flowers; but each group must be separately staged, and consist exclusively of fruit, Orchids, and hardy or tender plants or flowers respectively—not mixed together, excepting only that small decorative foliage plants may be used amongst Orchids and fruit, if desired.

3, The limit of 100 square feet does not apply to large plants placed on the floor; special arrangements should be made beforehand for such plants with the Superintendent.

4, No alteration is proposed in the existing rules with reference to the exhibition of new or rare plants, flowers, or fruits for the Society's certificates and awards of merit.—By order of the Council.

W. WILKS, *Secretary*, 117, Victoria Street, Westminster.

N.B.—Should at any time the entries of groups be so numerous as not to allow of all being staged in their entirety, the exhibitors will be informed how much less space than that they have applied for can be placed at their disposal.

It is a little surprising that some such conditions were not promulgated long ago in the interest of smooth routine and the prevention of disappointments.

ANNUS MEMORABILIS.

COMING events are now sufficiently foreshadowed on our horticultural programme to warrant the assumption that exhibitors this year will do their duty—that events to come off will be worthy, so far as one may anticipate, of this memorable year. Sufficient stimulus in the way of peculiarly, and one may say pecuniary, attractive prize lists has at least been provided, and it may be expected that points will be scored to the general credit. Good prizes—good shows. Well and good. Very good, too, is the outlook in this direction; yet somehow this, with other schemes propounded, and which we have no reason to doubt will be carried to a successful issue, seem to fall a little short of that loud national horticultural hurrah we would like to vent our feelings in, the echoes of which should resound down the corridors of time.

Higher horticulture is now a power with us, that probably does not obtain in any other land; we feel that it is so, that it is recognised to be so, hence we look around and ahead into the near distance to prejudge the effect of our practical paean of praise in the general rejoicing, and who will say amongst keenly interested ones that unqualified satisfaction ensues? We may, of course, take it for granted that of necessity, which necessity must for the nonce include a vast amount of luxurious decoration contributed by gardeners and gardening to refined festivity, the peaceful art will play no unimportant part; but familiarity with such displays upon not rare occasions of ultra-magnificence leads us to regard them as a matter of course, and one fails to find that deep and lasting impression we fain would engrave upon this particular page of the tablets of time.

It is not the summing up over that long period of sixty years which cannot but show a favourable balance upon the credit side, but it is this particular year's account which resolves itself into the question at issue, and whether it will or will not justify our hopes and fulfil our expectations. These remarks are really the sum and substance of some conversation with a gentleman recently, who pertinently asked, "What is it you gardeners want to do more than you have done in this year's horticultural programme? You must be satisfied in well doing, and possibly a margin will be found for something monumental which the near future will reveal." May it come quickly and be worthy of the object, I respectfully respond.

If there is any particular flower destined to glorify gardening and share the honours of this memorable year surely that is our English emblematic one, the Rose, and judging from present appearances it should be well represented at the time of our general

rejoicing. Perhaps we are too prosaic a people to embody sentiment in visible form by wearing the national flower; or perhaps it is owing to the unfortunately early date (April 23rd) fixed for the festival of our patron saint, St. George; or, again, to there being no mythological connection with him and the floral emblem, that so little is thought of either; but wherever the missing link may be we may, I think, regard it as the flaw which causes the Saint's day to pass unheeded, and the floral emblem, as such, to be unregarded. There is, however, for the latter a fine opportunity this year to do it justice.

Is there any Rose in particular to which has been accorded the honour of being our representative flower? I think not; and if not it is a question worth settling for good and all, and no better time than the present (the present year) could be found for doing so; but with all respect to Continental raisers our Rose must be of British breed and birth. Possibly among home specialists there is something good—very good, worthy of the year and the object, and ere 1897 passes a Victoria Imperatrice, Grand National, or Merry England will make its *début* and receive a hearty welcome.

Apropos of this, one wishes that some new and noble product of the vegetable kingdom might emphatically and indelibly mark for all time the horticulturists' loyalty of bearing the name of the illustrious lady, our Queen. Such we have truly in that grand annual Lily, that queen of the water nymphs, the Victoria regia; but one would like that name to be honoured by some grand old family of trees, such as the Wellingtonia, yet scarcely dare hope of there being anything so grand and noble and capably patriarchal destined to reach the shores and flourish in the climate of Old England.

Possibly we, as gardeners, should "be satisfied in well-doing," and possibly, too, there is something akin to vulgarity in ambition's desire to blow a loud horticultural blast on the trumpet of fame. If so it is, I think, pardonable. Probably landmarks of the long past shed a light upon the subject, and we may by analogy see what future generations may regard as the most valuable, as probably they will be the most lasting, mementoes of Victorian horticulture. This will be, as it is now, found in the scriptures of gardening work and thought. If we now regard the avidity with which the early examples of the then standard works, or even the stray scraps of horticultural literature, are sought for to tell us of those things, of those fashions, of those men and their manual works preserved to us by this means from oblivion, then I think we may here look for and hope to find satisfaction for our feelings.

Generations yet unborn must, one may reasonably expect, prize the standard literature of present-day teachings, which it is safe to say represent a degree of excellence previously undreamt of. Looking upon a gardener's library of to-day, embellished as it is by all that modern science and art can now accomplish in reproducing form and colour of luscious fruits; fruit alone, in its literature, possesses all that can satisfy Macaulay's New Zealander when he arrives. Can it be otherwise that our floral treasures, so largely increased, so vastly improved, with the present popular section of hardy plants so marvellously augmented, will not inspire some master hand to tell of them up to date; to be a guide to the present, a monumental work worthy of this advanced subject, worthy of a cause paramount if passive of this unique Victorian era.

It is on these lines we may, I think, hope to find, or rather for our Nova Zealander friend, to discover that horticultural aureole surrounding Victoria, rather than in the variorum of great shows, big prizes, or even those most commendable schemes already well in hand with which we gardeners would honour the Queen—God bless her.—ONE OF THEM.

VIOLETS.

THE popularity of many flowers seems to ebb and flow with the tide of fashion, but "sweet Violets" are always in demand during winter and spring. The most fastidious never seem to tire of them, but rather to require an almost unlimited supply of large, highly coloured flowers.

Plants growing in frames will now have practically finished flowering, and the time has arrived for taking the necessary steps to secure an abundant supply for next season. Methods of procedure seem to vary with different cultivators, and each pins his faith upon his own particular plan. Some maintain that by dividing the old plants and planting single crowns the best results are obtained; others aver that there is nothing like raising young plants from runners each year. Good results are without doubt obtained by either practice, and it is often necessary to employ both crowns and runners to secure the requisite number of plants. During the past season I have thoroughly tested several methods, and have fully convinced myself that the young plants produce the finest flowers, and for that reason I intend to depend entirely upon plants raised from runners in the future. Close observation should,

I think, show anyone why such is the case. It happens in this way. When plants are divided and the crowns inserted they form too dense a mass during the summer, for although the runners may be regularly removed suckers spring up from the base of the crowns, and by the time they are ready for planting in frames the plants are often from 9 to 12 inches in diameter. Grand plants, one is naturally led to think; and so they are in a certain sense, for all goes well with them till winter comes with its short, dull, wet, and cold days. Then damping begins, for no matter at how great a distance the plants may be set apart the mass of crowns forming the plant does not admit of a sufficient quantity of air and light to play around every leaf to enable them to perform their functions properly, and thus produce flowers freely.

The type of plant we should aim at securing is a moderate sized one with a single plump crown, and few but thick leathery leaves. A good sized frame will accommodate a large number of these, and yet allow every leaf to be fully exposed to light. The number of flowers produced per plant may not be great, but in a given space they will be as numerous as when big plants are grown, but the size and colour of the blooms will be infinitely more satisfactory.

In raising a stock of plants from runners various methods will suggest themselves to different cultivators, according to the circumstances in which they are placed. The plan I adopt is the following. The plants are lifted from a frame where they passed the winter; the soil is then forked up, pressed firmly, levelled with a rake, and given a sprinkling of sand on the surface. Strong runners are next selected, many of which have already emitted roots. These are then planted a couple of inches apart in the prepared frame, watered thoroughly, and kept close and well shaded till they begin to grow freely. They are syringed on the afternoons of bright days, more air being gradually admitted and shade withheld as growth progresses. With this treatment the plants will be ready for planting in their summer quarters by the end of May.

A border having a north or west aspect is a capital position for them. If the soil of this border has been dug during the spring, all the preparation required is to dress with soot, tread firmly, and level with the rake; the plants are then set a foot apart, taking care to leave the crowns slightly above the surface of the soil; a thorough watering is given, and repeated when required for a week or two should the weather prove dry. Culture during the summer months consists of persistently removing runners as they appear, so as to induce the plants to develop sturdy single crowns, and should drought set in an occasional watering will be necessary, sometimes with weak liquid manure. The hoe must also, as a matter of course, be kept going among them, with the object of keeping down weeds and securing a loose surface to the soil.

Violets should be placed in their winter quarters early in September, so as to become well established before wintry weather comes. Every spare pit and frame ought to be filled with them, as few flowers are so much appreciated during the autumn and winter months. In very cold districts it is a good plan to make up a hotbed for placing a few frames upon, as by so doing a supply of flowers is obtained during very severe weather, when the plants are almost at a standstill in cold frames; for the bulk of the plants, however, hotbeds are not necessary.

The only preparation needed is to place a few inches of clinkers at the bottom to serve as drainage, over these a layer of leaves, to be followed by 9 inches of good light garden soil, with which a little soot and salt has been mixed. If the surface of the soil is from 6 to 9 inches from the glass, the plants will have ample room to develop without coming in contact with it. In planting I allow the plants to stand just clear of each other, and I find that by keeping the runners regularly removed throughout the winter the space given is sufficient to prevent damping. In order to secure plenty of runners for spring planting three of the strongest runners are allowed to develop on each plant in a couple of lights. In these the plants are allowed more space when planted in the frames.

Good double varieties are Comte Brazza, white; De Parme, lavender purple; Lady Hume Campbell, lavender; Marie Louise, lavender blue; and Parmensis fl.-pl., white, striped rose. In Princesse des Galles we have the finest of all singles, producing flowers as large as a florin. It is a new variety, which should be secured by all.—D. W.

SPIREA THUNBERGI.—This charming Chinese species is the earliest of the shrubby section to open its flowers out of doors. The flowers are pure white, about quarter of an inch across, star-shaped, and produced thickly all along the previous year's growth. The habit of the plant is all that can be desired. The growths are long, twiggy, and somewhat pendulous, and at the end of March are thickly clothed with pale green leaves and pure white flowers, which make a striking contrast. When mature the bushes attain a height of 3 feet, with a diameter of 3 to 4 feet.—W. D.

OUR HARDY PLANT BORDER.

(Continued from page 309.)

“SNAPDRAGONS” are truly old-fashioned plants that are both ornamental and useful as many have proved, and certainly they have been quite as much admired as any of the other occupants of our borders. My earliest memories in gardening matters are associated with these plants, for I assisted in the propagation of three choice varieties, by making and inserting some thousands of cuttings, and well do I remember the pride with which the flowering of the plants thus obtained was observed. The varieties were pure white, deep clear yellow, and an intensely rich maroon, and either in beds or lines they had a most beautiful effect. It has seemed that I have never since found varieties equal to the yellow and dark forms; but these early formed ideas are often more vivid than subsequent impressions. A few years ago, however, I saw in one of the princely gardens of the Rothschild family a most harmonious arrangement of flowering plants, in which shades of yellow were the predominant feature, and amongst these a rich yellow *Antirrhinum* was employed in large quantities, and with excellent effect. This was the nearest approach to the favourite variety of my younger days, and I have since succeeded in procuring some of the same strain.

Antirrhinums have shared with other popular plants the attention of seedsmen, who have been so busily engaged during the present century in improving the different flowering plants which come within their scope. Some time since business took me to several seed farms in various districts of England, and I was surprised to find what numbers of distinct strains have been formed, especially amongst the dwarf types of “Snapdragons.” These come as true from seed as could be wished, the divergencies being not more numerous in many cases than the losses in raising varieties from cuttings, and it is obvious which is the quicker and more economical method of obtaining a large stock. They can be had in separate colours or mixed, while the striped or parti-coloured varieties are also very attractive, though I have a preference for the single tint flowers.

The purpose for which they were intended in our border was to constitute masses at intervals in contrast with the other occupants, and for this reason it was decided to start with seed of the best mixed strain obtainable. In this we were fortunate, for the seedlings raised proved most satisfactory, and formed some beautiful beds, including an astonishing variety of bright or delicate colours—maroon, crimson, purple, pink, mauve, yellow, cream, and pure white were all represented in fair proportions, the spikes closely furnished with large flowers, and the general habit of the plants bushy. The flowers are produced during a good portion of the summer months, and last a considerable time, except in very dry weather, when the buds soon become disfigured by the seed-bearing stems. From the most distinct of the varieties we have selected a few for increase by cuttings, and thus we have all that are required, either for special positions or mixed beds.

The cultural requirements of these plants are simple enough to bring them within the reach of all who have a garden; in fact, *Antirrhinum majus* as a wild British plant is found growing in similar situations to the common Wallflower, often on old walls or in situations where the soil is greatly inferior in fertility to that of the most ordinary garden. This is an indication that a rich soil is not essential, although of course there is a marked difference between the vigour and floral size of the wild plant and its cultivated descendant.

Though *Antirrhinums* will grow in almost all soils, one well-drained, not too dry, that has been thoroughly dug, and dressed with old decayed farmyard or stable manure, suits the plants admirably. The seed can be sown in early autumn or in April and May, but the sowings made in April, provided the soil is in the right condition, have given us the best results, particularly where the seed has been sown broadcast; and after a suitable thinning to allow the seedlings room to develop, they have been left undisturbed until they flowered. If the seed is sown later in the season it must be done sufficiently early to have the seedlings transplanted and well established before winter. They in either case can be placed out 6 inches apart, and they will make a full bed the first season, and they should be transplanted the next season to 9 inches or a foot apart, trimming the shoots in at the time, as they will grow freely and become bushy little specimens. Superphosphate, at the rate of 1 oz. to the square yard, has produced the most marked effects with these plants; the nitrogenous manures encourage too much stem and leaf growth, but the superphosphate unquestionably improves the size, colour, and numbers of the flowers.

As a margin to paths and roads, or for planting on banks or rockery borders, there are few hardy plants to equal the *Aubrietia* for spring flowering. Sufficient to stock a large garden can be

procured for a very moderate expenditure in seed, and when the plants have made a year's growth they will be compact tufts covered with purple flowers, and seen in large masses or lines they have a most pleasing effect. Several forms of *Aubrietia* of deep or brighter hues than the common type are sold under special names, but from the seedlings we have raised six very distinct forms have been selected, ranging from dark purplish blue to nearly white, and these are being increased by division. Amongst many thousand seedlings raised, however, there are very few that would be discarded for imperfection in colouring, and though the size of the flowers varies also, yet the majority are quite satisfactory.

Certainly in growth and floriferousness they leave nothing to be desired, and the beauty of plants a foot in diameter bearing countless flowers can be imagined, especially when they are contrasted with some other early flowering plant. Through March and April they continue attractive, while in some seasons the flowering is prolonged into May. We prefer sowing the seed about the middle of April, transplanting the seedlings as soon as they are large enough to handle conveniently, and scarcely any after attention is required. Ordinary soil suits them, and we have not found any appreciable advantage from the use of artificial manures except superphosphate, a very small quantity (about half that named for *Antirrhinums*) improving the colour of the flowers slightly.—A COUNTRYMAN.

(To be continued.)

AUBRIETIAS.

LOVERS of spring gardening—what a numerous family they are—should now find each day full of surprises and genuine pleasure, for notwithstanding the bitter winds and driving rains lately experienced every day seems to add to the “feast of beauty” to be seen in the gardens of this fair isle. Hyacinths, Tulips, Wallflowers, Violas, Myosotis, Arabis, *Limnantes* and Daisies brave the elements surprisingly well, and make a show of bright fresh beauty which is seen to advantage when the fitful sunshine bursts out in sudden splendour. The popular flowers already named are invariably grown in quantity.

Where spring gardening is a feature *Aubrietias*, as they well deserve, often find a place, but I think they ought to receive a much larger share of attention, seeing how extremely pretty they are. For permanent edgings to large beds they are unsurpassed, as they last a long time in flower, and throughout the summer they look fresh as the foliage is of an attractive glaucous colour. When once established they give little trouble for years, and in a geometrical flower garden are much to be preferred to edgings of *Arabis alpina*. *A. Leichtlini* is perhaps the very best variety, because it supplies a colour (rosy carmine) not very plentiful among spring flowering plants. Masses of it, when in flower, are extremely showy, and being very dwarf in habit of growth it is just the thing wanted for some beds when so many others around are occupied by taller growing plants. Those who are fortunate enough to possess a few good masses ought to have no difficulty in raising a large stock of plants to provide a display next year. To accomplish this every available cutting should be secured as soon as the plants have done flowering.

A good method of propagation is to insert the cuttings in light soil in a frame, which should be kept close and well shaded till the cuttings have rooted. Air may then be freely admitted till the young plants are large enough for transplanting in the reserve garden. In preparing the soil for their reception it must be made light and rich in order to secure strong plants by the autumn. Unless this good culture is given two seasons will be required to obtain fine plants, and there is nothing but the want of attention to prevent the accomplishment of the object in view in one season. *Aubrietias* may also be raised in large quantities by seeds sown at the present time.

Although seedlings do not come quite true to colour, they scarcely vary enough to make this a serious objection against them, and after the first season of flowering it is possible by a little selection to get an improved strain, even brighter in colour than the present form of *Leichtlini*. I find it a good plan to sow the seeds in boxes, which are kept in a frame till the plants are large enough for pricking out. When this is done they are set 3 inches apart, and later on alternate plants are removed to give those remaining room to develop. In this way fine plants can be obtained by November next.

A. deltoidea and *A. purpurea* are good old varieties, but they are quite eclipsed by such newer ones as *Hendersoni* and *græca superba*, each of which has large, well-shaped flowers, purple or violet-purple in colour. *Aubrietias*, when grown in borders or on rockwork, will continue to thrive and extend for years without

receiving any other attention than that of being kept free from weeds, and being given an annual dressing of manure or light soil; but when used as edgings in the flower garden it is necessary to replant every two or three years, otherwise they get somewhat patchy, as it is natural for them to ramble and establish themselves in all directions rather than be confined to a given space. A certain number of young plants should therefore be raised each year, so that whenever an edging needs uprooting a supply may be ready to take place of the old ones—not because old plants are of no further use, but because young ones are preferable for forming edgings. Those which they replace can then be planted in borders on banks, or in the many suitable positions always at command for them, as few gardens are so full of “good things” as to leave no room for more. Those who happen to preside over one in which such a happy state of affairs exists can easily dispose of their surplus plants by giving them to a less fortunate neighbour.

An idea I hope to carry out in a wide herbaceous border is next autumn to plant deeply, almost a foot apart, Tulips, then cover the surface with Aubrietias. The two will flower simultaneously, and go on satisfactorily for some years without being disturbed.—H. D.

TULIPA KAUFMANNIANA.

At the Royal Horticultural Society's meeting, held in the Drill Hall on March 23rd, Messrs. Barr & Sons and R. Wallace & Co. exhibited flowers of this handsome species, to which the Floral Committee adjudged a first-class certificate. It is a Central Asiatic species, that was, according to Johnson, introduced in 1877, and is figured in the “Botanical Magazine,” t., 6887. The flowers reach a height of upwards of 18 inches, and are pale lemon in colour, the base of the flower being clear yellow. More beautiful than the inner portion of the flower, however, is the reverse of each outer petal, which is of a peculiarly pleasing shade of red, giving to the flower prior to expansion a very fine effect. The illustration (fig. 70) was prepared from flowers staged at the Drill Hall on the above date.

FLOWERS OF THE STREETS.

ONE of the most interesting and cheering features of London streets at this season is furnished by the huge piles and baskets of golden Daffodils to be seen at those coigns of vantage by the Royal Exchange and the Circus—Regent's, Piccadilly, and Ludgate. In these dull days they afford the only bit of sunshine and colour on which the tired eye can rest and refresh itself. Then the florists' windows supplement this outdoor flower show with choicer and more varied material. Moreover, it is not only the tones of primrose, purple, and gold—the Narcissus and Violet—that one loves to look upon, but the enjoyment of the sweet, pungent, and characteristic fragrances of spring. The growing of flowers on the window-sill and verandah is becoming more popular—indeed, in some of the fashionable streets and squares there is a charming display. This outdoor window gardening not only “blesseth him that gives,” in putting a strip of delightful colour by his window, but it is also a refreshment of spirit to the passer-by.

I remember well a garden at Harrow some years ago. It was on the south front of a handsome school building, with borders of flowers, closely mown turf, smooth gravel paths, and walls wreathed with Roses, Jasmine, and Honeysuckle. There was a drooping Sycamore on each side of the gate, and half a dozen circular beds in the turf. It was evidently a pleasure for visitors from London and wayfarers to pause by the gate, refresh the eye, and inhale the fragrance of Roses and Stocks, Wallflowers and Mignonette. I remember, too, while walking among the Welsh hills, now and again being agreeably surprised by flashes of bright colours. What a change from the overwhelming preponderance of verdure! Here for a furlong is a Jericho wall, not altogether uninteresting, however, on this the shady side of it, for Dame Nature is pitiful—she adorns and beautifies even the waste places, and so she had scattered the spores of Adiantum and Polypody, Hart's-tongue, Trichomanes, and Wall Rue; but over the top one sees the handsome glossy leaves of Magnolia, and detects the rich fragrance.

A singular and diverse folk these English of the country side. Some put all their bright colours in front, and strip their green-houses to furnish an overwhelming display; while others build Jericho walls round their gardens, and content themselves with a pleasance that no one but themselves can see. From time to time, however, a door is left ajar, and one gets a peep of a delightful old garden. The brilliant hues merge into the restful shade of evergreens, and there are glimpses along the Yew avenues of green pastures—a river, woods, and Heath-clad hills. Those picture bits I treasure, and others doubtless, besides the lonely wayfarer, are

grateful to the amateur who left his garden door ajar. An agreeable surprise this in the country, how much more in the crowded town! Gratitude is due to the thoughtful, kindly souls who afford the passer-by those sparks of colour and suggestive whiffs of sweet odours. They doubtless enjoy these all the more from sharing them with the public.

There are few things more accommodating than Ferns, and, indeed, few plants more interesting. The most readily grown are Hart's-tongue, the Male Fern, and Polypody. At least a score years ago I reverted in the “G. C.” to one of our very handsomest annual climbers. The misfortune, however, as some would say, is that it is so common, and consequently so cheap, and now I can imagine some cute amateur—a “Mum”-growing cynic—as he discovers the secret, saying, “Yes, a bloomin' Nasturtium. Isn't that it?” Yes, and although the poor man can purchase a packet

FIG. 70.—TULIPA KAUFMANNIANA.

of seed for a penny, I doubt if it is possible to name a more beautiful climber. No, for cheapness and effectiveness nothing can compare with our homely Nasturtium. With a little arrangement of string or sticks, this annual may either be trained up either side of a window and over the casement, or allowed to droop in long wreaths over the window boxes.

It was George Glenny, that martinet of the florists, who dilated on the acres and miles of cottage and garden walls remaining all the year round only blank spaces. What miles of Board School walls might be utilised in London for the growth of such ordinary climbers as Nasturtium, Canary Creeper, Convolvulus, Cobaea scandens, and Scarlet Runner Beans. But let me return to those humble street florists, the costers. One wonders how poorer London could live without them. Apart from their well-stocked barrows being an agreeable feature of the streets, they are unconscious benefactors these costers, for no charge is made for

a glimpse at their mountains of Wallflowers, Daffodils, and Polyanthus, nor for the sweet odours that steal in through the open window as if to greet the pale invalid with the promise of spring.

It is early work attending the market, and then perhaps half a dozen miles to journey back before he starts on his beat. Of course, they get an experience in their dealing with flowers. There are miles of their stalls and barrows in the wide thoroughfares of south, east, and north. I pause at one of the barrows, and look over his stock. A favourite flower is the old crimson Clove, but one cannot always get it true. I take up a root, and glance at coster inquiringly. "Jacks?" I say. "No, sir," he replies, with a significant emphasis on the "No," then takes off the strip of bast, and breaks the lumps of black unctuous earth. "See, sir," says he, pointing to the root to show that it was from a layer. "No, sir; no Jacks here!" The reader will remember that round Hounslow there are acres of garden ground devoted to seedling Carnations. These find a ready sale among the costers, and are known as "Jacks" in the trade. They are purchased at about 4d. per dozen; then sometimes neatly labelled, and sold at from 2s. to 4s. a dozen. Some of these itinerant florists get little plots of ground for themselves, and become expert propagators. The most delightful bit of gardening in London is the long strip that stretches from Hyde Park Corner to the Marble Arch. There is no doubt that the example set there has been of service to gardeners elsewhere. One would wish, however, to see here and there a bed of hardy herbaceous flowers, such as an amateur might grow in his garden at home. There are scores of beautiful old flowers that one scarcely ever sees, except in such nurseries as Backhouse's and Barr's. Properly chosen one could have continuous flowering from Christmas Rose and Aconite to Michaelmas Daisy and Chrysanthemum.

Much more might be done in enlivening and beautifying the gardens of London squares; as a rule they are almost destitute of colour, worn, and neglected.

I have been lately from time to time through some Sussex villages, and have been surprised at the cheerful effect produced by the common *Euonymus* planted by cottage walls. Close by is a country village—Angmering—of a rather better type. The little houses are limewashed, and beside each door and window is a tall *Euonymus*, kept pretty closely trimmed. The plant, as the reader is doubtless aware, has glossy evergreen leaves, and at this season is making its early spring growth of a light yellow—almost a primrose colour. There are long hedges of it by the Undercliff, Isle of Wight. It is also used in the Scillies to protect the Daffodils from wind storms. The *Escallonia macrantha*, however, is now preferred. *Euonymus* would make a capital town shrub, keeping its cheerful verdure all the year round. It is of a brighter green than Ivy, and therefore of a more cheerful aspect. The shrub may be purchased for a few pence in Covent Garden and from the costers' barrows, and is suitable also for window boxes.—HERGA.

NATIONAL AURICULA SOCIETY'S SOUTHERN SHOW.

It was an unfortunate thing that the fixture for this meeting was of so early a date, but it could not very well be avoided. It simply arose from the very late date of the second Tuesday in April. The Society has to make its fixtures coincide with those of the R.H.S., and that Society cannot very well alter the dates of the second and fourth Tuesdays of the month for its exhibitions. Why, it may be said then, was not the 27th fixed on? I believe that it was considered that this would be too late, and there is no doubt that a day midway between these two would have been more suitable.

I may, I hope, be forgiven if I dissent from the opinions that have been given in some quarters with regard to the excellence of the show, for in the first place the northern exhibitors were entirely shut out, and those who know of the pleasure it is to see the fine stands exhibited by the Rev. F. D. Horner and others in the North will at once recognise what a loss this was; a loss which was felt in other ways, for it is not only the flowers but the men themselves whom we like to see; and though the pleasure of seeing Mr. Horner's flowers is somewhat of a tantalising one, for growers are not likely to have the opportunity of obtaining the plants for years to come, yet it is a pleasure that only a florist can appreciate to see what our champion Auricula grower can do in the way of raising new flowers. Thus it came to pass that there were fewer competitors than there have been during the last few years, and if the earliness of the date had an effect on the quantities of the plants, so, I think, it seriously interfered with their quality.

Most of the plants entered for competition bore the evidence of being subject to fire heat, and I do not think that Auriculas will endure this without resenting it; the foliage has a drawn and

flaccid appearance, while the truss of flowers is in too many instances loose and sprawly. Of course I may be considered as an old fogey, who can only praise things of the past and not of the present, but that is not so. I gladly acknowledge the advance that has been made in all classes during the past twenty-five years, but at the same time I cannot but notice what seem to me defects in culture. I do not know, and can only conjecture, that some of the plants have been somewhat highly stimulated, and this also tends to roughness and coarseness, which are quite out of place in the refined and beautiful Auricula.

Another point in which I am at variance with the present taste is that of the number of pips allowed to remain on each truss; it is noted as a meritorious point that a truss had fifteen pips. I believe that if half of them had been eliminated according to the old rule that an edge flower ought not to have more than seven pips had been adhered to a more elegant and beautiful plant would have been shown; in the old times seven was always considered quite large enough for any truss of a Show Auricula, and in my poor judgment that view was correct. A crowded truss does not give the idea of that refinement which ought to belong to the Auricula; and if the pips had been closely examined as the Lancashire men are wont to do a good many of them would have been defective.

On the other hand one was sorry to see in the Alpine class prizes given to flowers which had not more than two expanded pips. Another cause of regret which was universally expressed was the retirement of Mr. T. E. Henwood, he having been compelled, owing to ill health, to part with his collection. It is to be hoped that this may only be for a time, as we shall be sorry to lose permanently so enthusiastic and successful a grower.

With regard to the varieties exhibited, it is remarkable how some of them hold the field. If the Rev. F. D. Horner and Prince of Greens are in good condition, no other green edge can approach them. I do not include in this Mrs. Henwood, which promises to be, when in good form, a formidable rival to these two; then amongst grey edges George Lightbody still is unsurpassed, and some of us would say unsurpassable. Acme amongst white edges holds much the same position, although it is very difficult to get a large plant of it, owing to its tendency to break up into offsets; while amongst selfs it would be difficult, when Heroine and Mrs. Potts are shown, to find any other flower that will beat them. I was interested to notice how the flowers raised by my late friend Mr. Woodhead still hold a prominent place. He only raised four varieties—Black Bess, Mrs. Dodwell, George Rudd, and Rachel; and when one looks into the prize lists, one is sure to find one or other of these flowers.

The same cause which interfered with the general character of the show interfered with the production of seedlings. Few were exhibited, the most conspicuous being a green edge, named Greenfinch, raised by Mr. James Douglas and exhibited by himself; this is a flower of good properties, the green edge being good, the body colour dark, and the tube bright. This flower received Mr. Martin Smith's prize of half guinea for the best green-edged seedling and also a certificate of merit, the worst point about it being its name, as Mr. Horner exhibited one two or three years ago under the same name.

Of the newer flowers Mrs. Henwood, to which I have already alluded, and Abbé Liszt were the most remarkable. This latter is a fine flower, but there is a narrow thread of grey round the edge of the petals which detracts from its purity as a green edge. The champion prize was gained by Mr. Phillips for a fine plant of the Rev. F. D. Horner, showing how this valuable variety holds its own. Such are the impressions of an old Auricula grower, who, it is true, has been brought up in a strait sect, but who, notwithstanding, has the notion that the rules laid down by the earlier school of florists was not far from being right.

I have said nothing about the Alpines or Fancies, as I do not profess to know them; but I cannot but allude to three baskets in which Auriculas (both Show and Fancy) are exhibited without pots and with a groundwork of the smaller foliage Saxifrages, having a very pretty effect.—D., Deal.

FINE SEAKALE.—Mr. Henry T. Martin sends us from the Gardens, Stoneleigh Abbey, some of the finest Seakale we have yet seen—large, tender, and pure. The plants must have been admirably grown, and the crowns large, for some of the heads girthed $7\frac{1}{2}$ inches, and were very heavy; length, 7 inches. Mr. Martin observes that he has been cutting 30 lbs. a week for the last six weeks, and there is not much wonder that such produce should be in great demand. It is doubtful whether the variety is different from that generally grown, and the point can only be determined by the summer growth. We rather attribute its excellence to good management as we have seen other heads apparently identical in character, though not quite so large.

ONCIDIUMS OF THE MACRANTHUM GROUP.

So varied and beautiful are the species belonging to this genus that one may almost be satisfied with a collection of them alone. There would not be a month in the year but some of them would be in flower, and the exquisite combinations of colour occurring in some of the species, the immense panicles of others, and the refined yet telling appearance of one and all, would make the choice a good one. Not the least charming are the kind with long twining scapes of showy blossoms included in the *O. macranthum* set, and as these are often set down as difficult plants to manage a few lines on their culture may prove of interest.

Perhaps the most frequent of all mistakes in their culture is trying to force them to rest, and here it may be noted that the flower spikes must not be looked for at the side of the natural pseudo-bulb as in many other species. This fact is sufficient to account for some failures. The beginner sees the young shoots breaking at the side of the pseudo-bulb, and comes to the conclusion that he has been treating it wrongly, and commences a starving course of treatment. This is quite wrong. The spikes usually appear when the new shoots have made some inches of growth, and to withhold sustenance from them at the outset gives them about the worst start possible.

I have in a somewhat lengthened experience of this class of Orchid found it much better to let the plants have their own way, and by observation—timely observation by the way—of the roots to encourage them when they are seen to be extra active and *vice versa*. Note the root, for instance, in nine cases out of ten when the spike is growing, and the pseudo-bulb beginning to take its true shape, as distinct from a growing shoot. The plant has the dual strain upon it, and the roots will be seen plainly foraging as it were for moisture, to maintain the lengthening spike, and to store a due quota of nutriment in the forming pseudo-bulb.

This is the time to be on hand with a full supply of moisture, and afterwards, when the plant has matured its growth, and the strain of flowering is over if they seem inclined to rest let them do so. This seems to me to be the crux of the whole affair as far as root moisture is concerned, and by following up this mode of treatment I have been fairly successful. Another point not to be lost sight of is the fact that these spikes are many months upon the plant coming to maturity, and the strain of them should be relieved by cutting the spikes as soon as possible after they open. It is a good deal better to cut them after, say, a fortnight or three weeks' flowering, than to leave them on until they fade, and run the risk of severely checking the plants. The little side sprays last a long time in water, but if cut entire the spikes will soon flag.

The most airy part of the cool house should be chosen for them, as here they will be least likely to be attacked by thrips, a deadly foe to all in this class. The atmosphere, as well as the roots, must always be kept moist, and during the summer months it is almost impossible to shade too heavily. Any slackening in the atmospheric moisture at the time when the spikes are just forming will assuredly cause these to become blind and dry off, and if during very severe weather the cool house is at all likely to be kept on the dry side for any reason, I should certainly remove any of these plants that chanced to be forming their spikes to warmer, because moister quarters.

With regard to root run for them, they are best grown in a rough and very open description of compost. Good peat-fibre and sphagnum in equal proportions should be mixed with nearly its own bulk of crocks, potters' ballast, or charcoal in lumps as large as a Walnut. The pot must be fairly large in comparison with the size of the plant, as the roots are strong and vigorous, and are better inside than rambling about over the outside of the pot. In repotting keep the leads fairly low down, as the plants are in the habit of pushing one pseudo-bulb considerably above the last one, and if too much elevated they soon get out of touch of the compost.

The typical *O. macranthum* (fig. 71) is one of the best and showiest of all, the flowers occurring in great numbers upon the scapes. The sepals are brownish yellow, the petals bright golden yellow, the lip purple with a white crest. Another beautiful kind is *O. serratum*, very similar in colour to the last named, the petals having the peculiarity of turning inward until they meet over the column. Others more or less similar are *O. chrysodipterum*, *O. luteus*, *O. hastiferum*, possibly a variety of *O. macranthum*,

O. superbiens, and *O. lamelligerum*. These it is hardly necessary to describe in detail, but one more at least is worthy of this, *O. undulatum*. A good form of this is a really beautiful sight when in bloom; the sepals are reddish brown, the petals pure white, streaked and spotted with yellow and purple, the lip deep purple, a truly beautiful disposition of colour.—H. R. R.

ORCHIDS AT ASTON HALL.

When visiting Aston Hall, Oswestry, some time ago, I was much struck by the fine collection of Orchids growing there. One house especially attracted my attention, it being almost entirely devoted to Cattleyas and Cypripediums, all of which, whether in or out of flower, are a picture of health, cleanliness, and high cultivation. Colonel Lloyd, who is a very enthusiastic gardener, has spared no pains in getting together not only a large collection but a choice one, and many rare kinds were to be seen in flower. Although the autumn Cattleyas were over the Cypripediums were just at their best, *C. Læanum* being in strong force. This beautiful variety appears to be a great favourite everywhere amongst

FIG. 71.—ONCIDIUM MACRANTHUM.

Orchid lovers. It resembles *C. Spicerianum*, but the scapes are rather longer. The flowers have an emerald green base and radiating mauve spots running upwards into the white parts, while the lip is of a shining brownish red. Amongst many others I noticed *C. Charlesworthi*, *C. violaceum*, and *C. Chamberlainianum*, all producing flowers of good size and substance.

Sophronis grandiflora is also grown remarkably well, and several plants were in flower. The Cattleyas were a picture to those interested in them, for never have I seen a healthier collection. No gardener need feel afraid at allowing his Cattleyas to shrivel in the resting season after the success that has followed that process at Aston. Mr. Townsend, the gardener, considers it is the making of them, and is not satisfied by allowing the bulbs to begin to shrivel before watering them, but allows them to get to such a stage as would frighten many an orchidist. Certainly it makes them break more freely afterwards, but few would care to follow it to such an extent.

Not only are Orchids a speciality, but also Roses and Chrysanthemums, and it is difficult to say which are done the best. The fact that Mr. Townsend secured the cup at Liverpool this last season with his 'mums speaks for itself; but the Roses have to be seen in their home before anyone is able to form an idea what they are like. Most of them are Teas, and, like the Cattleyas, are the strongest I have ever seen under glass. They are most of them grown in pots in a house between 60 and 70 feet long. The fruit trees indoors are also in good condition, and everywhere appeared in perfect order, reflecting great credit on the energetic gardener.—GEO. BURROWS.

“JOURNAL OF HORTICULTURE” EDITORIAL DEPARTMENT.—

From the present date, and until further notice, it is particularly requested that all letters and parcels intended for the Editor, also all communications for insertion in the “JOURNAL OF HORTICULTURE,” be addressed to S, Rose Hill Road, Wandsworth, London, S.W. N.B.—Business letters and advertisements must be addressed to the City Office.

— WEATHER IN LONDON.—Holiday makers have had to put up with some adverse weather this Easter, as they have had to do before and possibly will have to do again. There were glimpses of sunshine on Thursday, but Good Friday was a thoroughly wet day, while Saturday was very little better. Easter Sunday was a glorious day, and the hopes of the trippers rose proportionately, and were maintained until Monday evening when rain again fell. Tuesday was fine, and Wednesday damp.

— WEATHER IN THE NORTH.—The past week has embraced samples of all sorts of weather. A great deal of rain has fallen, and on the 14th heavy showers of snow and hail, with several loud thunder-peals, occurred. The hills all round were again covered with snow. The evening of Monday was very wet; Tuesday morning was bright and mild.—B. D., S. Perthshire.

— NEWCASTLE-ON-TYNE SUMMER FLOWER SHOW.—We have received a copy of the schedule of prizes to be offered for competition at the Newcastle Flower Show on Thursday, Friday, and Saturday, 8th, 9th, and 10th July, in the recreation ground. Since last year the schedule has been increased in several instances. The following are some of the principal prizes:—Roses, £75; table decorations, £23; Pansies, £14; herbaceous flowers, £13. The Committee has arranged to re-strike the medal of the Society, and gold, silver, and bronze medals are included in this year's schedule. Copies of the schedule may be had on application to the Secretary.

— LONGFORD HOUSE, ISLE OF WIGHT.—This, the private residence of Mrs. Rylands, is situated at the bottom of the village of Haven Street, and has a pleasant and extensive inland view. The gardens adjoining are under the capable management of Mr. J. Barkham, F.R.H.S. During a flying visit the other day I noticed a fine house of Cucumber plants, which were very prolific, producing from three to five fruits at a joint. The variety he informed me was a cross between Rochford's Seedling and Sutton's Improved Telegraph. Tomatoes in pots were bearing a good crop of well shaped, highly coloured, and excellently flavoured fruits. To tourists interested in gardening a visit to Longford House would amply repay them, and they would have a hearty welcome from Mrs. Rylands' able gardener.—S. H.

— DOBBIE'S DAHLIA BOOK.—This free rendering of the title of the first of Mr. William Cuthbertson's horticultural handbooks slides smoothly from the pen, as it will not improbably fall trippingly from the tongue when copies are being ordered by the “trade” for distribution among florists. It will be proper, however, to give the full title—“The Dahlia: Its History and Cultivation” (edited by Mr. W. Cuthbertson and published by Messrs. Macmillan & Co., Ltd., London, and Messrs. Dobbie & Co., Rothesay). The editor has written the preface, and pithily observes, “The florist differs from the botanist in his relation to plants. The plant as it is is the province of the botanist. The plant as it can be developed is the province of the florist.” In this handbook, then, may be found the development of the Dahlia. Mr. Richard Dean records its history, Mr. John Ballantine treats it botanically, chapters on propagation and exhibiting have been entrusted to Mr. Stephen Jones, and on cultivation to Mr. Robert Fife, while the editor has compiled the most complete catalogue in existence of varieties now cultivated by large growers, and from which excellent selections are given. Mr. Cuthbertson also writes hopefully of the future of the Dahlia, describing it as “without doubt the most perfect of Flora's creations from a true florist's point of view.” This handbook contains eighty pages of interesting, useful, well printed matter; also attractive illustrations, and will be acceptable to the Dahlia growing community.

— GARDENING APPOINTMENT.—Mr. J. T. Stoney, for the past two years foreman at Powis Castle, Welshpool, has been appointed gardener to H. B. Gilmour, Esq., Underlea, Aigburth.

— CERTIFICATED NARCISSI.—The Rev. G. H. Engleheart was awarded first-class certificates for both Narcissus Beacon and Narcissus Snowdrop, not awards of merit, as stated in our last issue.

— THE ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, April 27th, in the Drill Hall, James Street, Westminster, 1 to 5 P.M. A lecture will be given at three o'clock by Mr. A. Dean on “Winter and Spring Bedding.”

— THE APPLE BLOSSOM WEEVIL.—This and other beetles injurious to the Apple are concisely treated in pamphlet form (Headley Brothers, Ashford) by Mr. Fred. V. Theobald, M.A., F.G.S., of the South-Eastern Agricultural College, Wye. It is in large part descriptive of the habits of the enemy, which punctures and ruins the blossoms; but suggested preventives as remedies are given, including kerosene emulsion, made as follows:—“Dissolve 2 lbs. of soft soap in 1 gallon of boiling water, then add to the dissolved soap 2 gallons of kerosene oil; churn the two well together until a complete creamy emulsion is produced. One part of this emulsion can be mixed with from forty to fifty parts of water. The concentrated emulsion will keep for some time.”

— A NEW INSECTICIDE—ARSENATE OF LEAD.—Mr. Theobald received this from the Report of a meeting of Australian fruit growers, and observes:—“This poisonous substance, used for spraying, seems to have many advantages over Paris green and other arsenites. As it is a more powerful insecticide than the other arsenites, it may have the effect of killing the adult weevils treated of here. It certainly kills an equally hardy weevil—the Corn Weevil (*C. granaria*), although it could not be employed for that purpose. Its great advantage is, that if properly proportioned it will not damage the leafage at all, however concentrated it is used. It is mixed in the following way:—Take 11 ozs. of acetate of lead and dissolve in 1 gallon of water, and 4 ozs. of arsenate of soda dissolved in the same quantity of water; then mix these two together, and pour into 100 to 150 gallons of water for use. The cost of this insecticide comes to about 4d. 100 gallons. It is successful in regard to leaf and bud-eating larvae, and is well worthy of a trial by all fruit growers.”

— EARWIGS FLYING.—Referring to the circumstance of the female beetles (*Anthonomus pomorum*) having strong wings, but seldom using them, Mr. Theobald points out that the common earwig (*Forficula auricularia*) has most ample wings, but so rarely uses them that he thinks the only instance of this having been observed is a record of his own in the Entomological Journal in 1896. If he had worked for many years in Dahlia plantations he might have seen dozens and felt them, too, if they had butted his eye. We have from time to time seen scores of earwigs use their wings years before the Entomologist's discovery, and so must have many gardeners.

— THE WEATHER AND FRUIT PROSPECTS.—The weather of late has been of a very cold and winterly character. The month was ushered in by a cold easterly wind, accompanied by driving snowstorms, the ground being partially covered in the early morning, followed by more or less of frost on most nights. On the 7th inst. there was a very winterly morning with a N.E. wind. Snow fell thick and fast for upwards of two hours, covering the ground nearly 2 inches deep, but it soon melted. On the 11th (Palm Sunday) 11° of frost were registered. On the 16th (Good Friday) the weather was of a very boisterous character from 3 to 4 P.M.; a heavy thunderstorm broke over this neighbourhood, the lightning was very vivid with heavy peals of thunder, followed by a downpour of rain and hailstones, which continued for about half an hour, the ground being quite white for a time. This produced 0.65 of water. It is twenty-one years since the memorable Good Friday when there was a deep snowstorm, and so much damage was done in this neighbourhood to many fine Cedars of Lebanon and other trees. Grave doubts are entertained as to the safety of the early fruit blossoms. It is feared that Gooseberries and Currants have suffered by the late frosts; the foliage has a pale and sickly appearance. Peaches and Nectarines on unprotected walls seem to have set fairly well, but Apricots are a failure. Plum and Cherry blossom is abundant, also early Pears, but a good deal cut by hailstones. The Apple blossom, still in embryo, we hope is safe, but the budding foliage has a sickly and bleached appearance.—G. R. ALLIS, *Old Warden Park, Beds.*

— **NATIVE GUANO.**—From the Native Guano Co., 29, New Bridge Street, Blackfriars, we have received a pamphlet containing sixty pages almost exclusively occupied by testimonials as to the quality of this food. There are letters from some of the best-known gardeners in all parts of Great Britain and Ireland, and the unanimity with which they agree as to the merits of the product is ample testimony of its worth.

— **PANSIES AND VIOLAS IN POTS.**—We have pleasure in sending you herewith a few blooms from our Pansies and Violas. The plants were potted in January, and have since been grown in a cool greenhouse, where they are flowering beautifully.—**DOBBIE & CO.** [We know how attractive these plants are when flowered in pots early in the season, but unfortunately the box of flowers posted on the 14th inst. did not reach us till the night post of the 20th, and were, as may be imagined, a mass of dry, crumpled, colourless lumps—in fact, dead.]

— **WHITE BROCCOLI.**—This term is very familiar, and was fully justified by the beautiful specimens exhibited by Mr. Empson at the Westminster Drill Hall last week. They were not large, but quite large enough, and not cream coloured, but a clear white, like Cauli-flowers. Whether they underwent any manipulative blanching process is not known, but whether they did or not, they were the whitest Broccoli we have seen of some thousands in London this spring. The variety was named Carter's Perfection, and the heads for closeness and purity would be hard to surpass.

— **HORTICULTURAL CLUB.**—The monthly dinner and conversation of the Club took place on Tuesday evening last, when there was a good attendance of members and friends. Mr. H. J. Veitch, Vice-Chairman of the Club, presided, and there were present Messrs. H. J. Pearson, Francis T. Rivers, H. Rivers, J. E. Cockett, J. Cockett, jun., H. Selfe-Leonard, James Walker, George Paul, C. E. Shea, J. Assbee, Dr. Ernest D'Ombraïn, H. A. A. D'Ombraïn, Philip Crowley, and the Secretary. A very interesting paper on the Flower Gardens of Victoria was read by Dr. Ernest D'Ombraïn of Melbourne, in which he showed how erroneous were the opinions often entertained in this country as to the soil and climate of Victoria. He also gave an account of plants and flowers which flourished best in the Colony. An interesting discussion followed the reading of the paper, and many questions were asked on some of the points elicited by the lecturer, to whom, on the motion of Mr. Veitch, a cordial vote of thanks was given. We hope to give this paper in a future issue. Thanks were also given to Mr. Geo. Mount for some beautiful Roses which he sent to decorate the table.

— **REPORT OF TOMATO CULTIVATION.**—Mr. W. Neild, F.R.H.S., has furnished a report, as indicated, to the Cheshire County Council, as founded on experiments conducted at the Agricultural and Horticultural School at Holmes Chapel. The varieties grown were the Hackwood Park and Neild's Seedling, the last named having been granted an award of merit in the Chiswick trials last year. Mr. Neild seems to have been surprised by the result of ten experiments in manuring. Of these it may be briefly said that a mixture of nitrate of soda and muriate of potash, nitrate of soda alone, and sulphate of ammonia alone, had the best effect. He goes on to say, "Potassic manures have long been considered the best for Tomatoes, and yet when muriate of potash was applied by itself it proved to be a failure." In the first place we doubt if potash alone, and in the absence of other food essentials, has been recommended as the "best" manure by any competent adviser. These Cheshire experiments have not proved the inutility of potash in the least. Had the plants and fruits been analysed it would have been discovered that they had obtained all the potash they required where there was sufficient available nitrogen in the soil to enable them to benefit by it. Mr. Neild has really discovered that the "heavy and rather adhesive" soil contained an ample store of potash (as such soils often do), while light or sandy soils are as often deficient. This is represented in Mr. Dyke's table on page 312 last week, and he also shows that the soil in which muriate of potash had no effect might even contain potash at the rate of 24,900 lbs. per acre in a depth of 9 inches, but lying comparatively inert by lack of sufficiency of available nitrogen. He has also discovered that his soil is deficient in active nitrogen, and there are thousands of acres of land in much the same condition. Some of the finest crops of Tomatoes, averaging 22 lbs. a plant, were grown in sandy soil, and muriate of potash was a chief factor in their production; but though it was not given alone they could not have been produced without it in such soil. Referring to size of fruits, Mr. Neild found that in nearly every instance smooth medium-sized samples realised from 1d. to 2d. per lb. more than the larger fruits did. He also gives excellent advice on preparing and packing fruits for market.

— **THE ROYAL GARDENERS' ORPHAN FUND.**—We have the pleasure to announce that Mr. Leonard Sutton of Sutton & Sons, Reading, has very generously sent a donation of £100 to the Royal Gardeners' Orphan Fund. We are requested to remind our readers that the annual festival dinner of this charity will take place on Friday, April 30th, at the Hotel Cecil, Charing Cross. Gentlemen who may be desirous of attending the dinner will please communicate with the Secretary (Mr. A. F. Barron, Chiswick), by whom donations to the Fund are most thankfully received and gratefully acknowledged.

— **HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.**—The annual dinner of the above Society took place on Monday, April 12th when the chair was occupied by W. J. Wharwick, Esq., President of the Society. Upwards of sixty members and friends partook and thoroughly appreciated the good fare provided. The usual toasts were submitted and duly responded to, including that of the "Press," both the local and the *Journal of Horticulture*. A capital musical programme was most ably rendered by Mr. A. Newton's Kingston quartette party, who displayed exceptional ability in entertaining. Collections were made on behalf of the Gardeners' Orphan Fund and the Gardeners' Royal Benevolent Institution. The National Anthem brought to a close a most enjoyable evening.—F. L. T.

— **EASTER IN THE ISLE OF WIGHT.**—At this festive season there is a great demand for flowers in all parts of the island, and it undoubtedly behoves florists to cater sufficiently for the public wants, and if possible to have such a show of bloom in their shops that passers cannot resist the temptation to buy. This idea is adopted by Mr. Walter Gihson, Sandown. Anyone who passes the shop in High Street will see a miniature flower show of excellently grown, well bloomed, and nicely arranged *Lilium Harrisii*, *Azaleas*, Tulips, Lily of the Valley, and *Polyantha* Roses, with foliage plants intermixed, which gives the whole a tropical appearance. It is patent to all that the florist or fruiterer can draw or drive customers away to a large extent by the way in which his goods are exposed for sale.—S. H.

— **SCHIZOCODON SOLDANELLOIDES.**—It is surprising that this plant, of which a figure is given on page 323, has not found its way more generally into cultivation in England. It is offered in the Japanese nursery catalogues, both at Yokohama and Tokio, at a price equal to about 2d. a plant, and the transmission by parcel post costs 1s. 10d. for 3 lbs. weight, and is performed in a time which brings these plants to England alive. I had some plants imported and given to me by a friend, but I am afraid I shall not succeed with its cultivation, as *Shortia galacifolia* and *Galax aphylla*—the two plants most nearly allied to it both in nature and habit—fail utterly here. It would probably succeed in Mr. G. Wilson's garden at Wisley, where the two species I have mentioned above thrive admirably. Now the plant can be obtained so easily and cheaply, it is to be hoped we shall soon know more of the circumstances and surroundings necessary for its successful cultivation.—C. WOLLEY-DOD.

— **CARROTS.**—I am hoping this season to be able to get a pretty correct line as to the diversities or otherwise that may exist amongst Carrots, having sown seed on excellent sandy soil of both British and French nomenclature. That some of these are identical, though not in name, there can be no doubt—indeed, the packet illustrations of the French stocks show exactly what these varieties under French appellations are of British designation. The former nomenclature, however, is not suited to our tastes, as too long and descriptive. For that reason we cannot complain if British seedsmen give to the stocks British appellations; but could wish they would be unanimous in adopting the same designation, and not employing a different one in every diverse catalogue. British seedsmen, no doubt appreciating home growers' tastes, keep almost exclusively to red varieties. The French not only grow all these, but pink, lemon, and white ones also. Even the long red coreless, or soft-fleshed sausage-shaped Carrot does not seem to be on offer here. I have this variety sown, as also white, lemon, and pink-rooted varieties. Gardeners generally limit themselves to the early French Horn, otherwise Early Gem, or Early Forcing for frames; Champion Scarlet, or Scarlet Model, and St. Valery, otherwise New Intermediate or Matchless. The long Altrincham and Red Surrey are much less grown. No doubt the three varieties named serve every useful purpose in gardens, and are the best of the batch. None the less we may not shut our eyes to the merits of other varieties that have features of special excellence. It is one of the great merits of the Carrot that we can have it in good form literally all the year round.—A.

— **HAMBURG EXHIBITION.**—We are informed that at the Hamburg Exhibition, extending throughout the summer months, prizes to the amount of £7500 will be given. This considerable amount has been raised by subscription, the Emperor and many nobles, besides the officials and citizens of Hamburg, having given substantial assistance. In addition to money prizes several medals will be awarded. English visitors must remember that the next show opens on May 1st. The route by Great Eastern Railway and General Steam Navigation Co.'s express trains and magnificent steamers will be found quick and comfortable.

— **SHOWS AT CARDIFF.**—Two schedules of shows to be held in Cardiff during 1897 have reached us. One is of the Cardiff and County Horticultural Society, whose exhibition will be held on August 11th and 12th, in the Sophia Gardens. The classes are numerous, and the prizes, as a rule, high, at least sufficiently so to promise a first-rate show. Schedule No. 2 is of the Cardiff and District Chrysanthemum Society, of which the show will be held in the Park Hall on November 3rd and 4th. There are open and restricted classes, and it is to be hoped that the exhibition will be an unqualified success.

— **SUTTON'S AL KALE.**—When at Woodside, Farnham Royal recently, I saw a breadth of this wonderfully fine green Kale, with respect to which it was not at all needful for Mr. James to draw attention and to praise it. The breadth told its own tale. The variety is of the tall Scotch character, but has leafage much more densely set on the stems, and carries a thick massive head. How different in this respect from the comparatively thin-leaved head of the common form. But the great feature of the Al variety is its wonderful sprouting qualities, for the stems are so thickly coated with sprouts that it is difficult to keep them fully hard gathered. Whilst pieces of common Scotch in other gardens were stripped bare this greatly improved form was giving a literal wealth of early sprouts. It is a grand addition to our late winter garden Kales.—A. D.

— **"FLORILEGIUM HARLEMENSE."**—Such is the title of a work of which we have received two parts, after the style of the "Album Van Eeden," that is now being published under the auspices of the "Algemeene Vereeniging Voor Bloembollencultuur" at Haarlem, Holland. The plates are magnificent chromo-lithographs after well known Dutch artists, and the admirably written letterpress accompanying each is given in four languages—Dutch, English, French, and German. The pictures are almost perfect portrayals of life, and editors in their selection, artists in their paintings, and printers in their reproduction are deserving of every congratulation and support. The plates, which are all of bulbs, as is inferred by the title, that have already appeared, are as follows:—Hyacinth La Grandesse; single Tulips, Keizers Kroon, Pottebakker white, Proserpine and Vermilion Brilliant; Narcissus pseudo-Narcissus maximus, bicolor Horsfieldi, and moschatus albicans; Hyacinth, Gigantea; single Tulips, Chrysolora, Canary Bird, Wouwerman, and L'Immaculé; and Fritillaria imperialis rubra maxima. The work will appear in four parts yearly, the annual subscription being 15s., and a specimen copy may be had free on application to the publisher, De Erven Loosjes, Haarlem, Holland.

— **HARDY FRUIT BLOOM.**—Whatever may be the ultimate product it is certain that fruit trees on every hand are making a magnificent floral display. It will be interesting later to compare results with present promise when the annual fruit census is taken. Pears are universally blooming, almost marvellously, the flowers being so densely set on many trees that little but the bloom is seen. A remarkable sight just recently has been Mr. W. D. Blackmore's garden at Teddington, where the many trees of free growth tower up above the enclosing walls, and show every one irrespective of variety literally a mass of bloom. Whether this abundance of flower is good or the reverse remains to be seen, but there have been previous seasons when such great masses of bloom were seen and the fruit product has been indifferent. The present abundance has had in its favour abundant moisture, whilst the individual flowers are large. Some no doubt have suffered from frost, but the greater portion has escaped harm. It is nothing new to see Cherries blooming profusely. The trees nearly always do so, yet the fruit crop appreciably varies. Much now depends on the nature of the weather for the next week or two; at present it is wild and stormy, and not all that can be desired. Plums are blooming moderately. The trees will no doubt carry an ample crop of their soft fruits without being unduly exhausted. As for Apple trees, they will in every direction be grand masses of colour in a few days, and so far no harm has been done. The present prospect for a fruit crop is of the very best.—D.

— **SOUTHPORT AND BIRKDALE GARDENERS' SOCIETY.**—A copy of the annual report of the Mutual Improvement Department of this Society has reached us. From this it appears that excellent work is being done in diffusing knowledge on practical points in gardening by the aid of papers by men thoroughly versed in the best methods of procedure. Such societies as this do a great amount of good to the world of gardening, and are deserving of all support. The Secretary, Mr. H. R. Goddard, having resigned, Mr. J. E. Swift was elected to fill the vacancy, and his address is 11, Pine Grove, Southport.

— **UNWELCOME GUESTS.**—Messrs. Laing & Mather, the well-known nurserymen of Kelso-on-Tweed, are renowned for the courtesy with which they greet visitors, but they have recently had invaders who were decidedly unwelcome. They came in the form of voles or field-mice, which mustered an army, and ate out the points of a plantation of two-year-old Scots Firs. The firm, not being sure of the cause of the trouble, sent specimens of the damaged stock to Mr. Malcolm Dunn of Dalkeith, who pronounced the enemies to be voles. Traps were set after the whole of the damaged trees had been burned, and a good "bag" was the result. We trust Messrs. Laing & Mather will come off victorious in their war with the rodents.

— **SEAKALE.**—Mr. C. Herrin is so much impressed at Dropmore with the exceeding value of a good supply of Seakale roots for forcing and blanching, that he puts out annually several thousands of root cuttings, quite a large breadth of ground being thus occupied. Blest, indeed, is the gardener in winter who has his quiver full of Seakale roots, for he can run a supply of the delicious blanched heads for a period of six months with the least possible trouble. None is blanched in the ground at Dropmore, because such methods would interfere with the routine of cropping in the spring. The latest can easily be blanched with the aid of leaves only, and it is so produced beautifully white and perfectly developed. It is surprising that the production of big breaks of Seakale roots in this way is not common practice in every large garden.—A. D.

— **SUTTON'S FAVOURITE CABBAGE.**—This compact, firm, tender looking little Cabbage, as exhibited at the Drill Hall last week by Mr. G. Wythes, was, as stated in our report of the meeting, admired by many visitors. At this season of the year, when the ordinary winter Greens are as a rule getting exhausted, or the flower stems tough and stringy, a supply of such Cabbages would come as a boon to many a gardener. Mr. Wythes showed one of the plants as drawn from the ground, and it was scarcely less remarkable for its short slender stem than for its close shapely head, with the fewest possible loose leaves for removal. Dwarfness is, however, very much a question of thin sowing and intelligent management. The Cabbages were only a little larger than good sized plump partridges. We do not know Mr. Wythes' planting distance, but it is certain that he could have grown them as they were by allowing each plant a square superficial foot of space. Cabbages decidedly inferior to those in question have been selling freely in London, and are yet at 1½d. each. An acre of the Wythes brand, if fortunately free from blanks, would at 1d. each be worth upwards of £180. There is thus money in Cabbages when full crops of the right sort are placed on sale at the right time, and that is when London is hungering for the first spring supplies.

— **SOCIÉTÉ FRANÇAISE D'HORTICULTURE DE LONDRES.**—The Secretary of this Association, which has now reached its eighth year, has forwarded to us the Bulletin of 1896, and if judgment were passed according to the size of the book the verdict would be distinctly favourable, as it reaches a total of 140 pages. The favourable impression created by the clear printing on slightly toned paper is justified on a perusal of its contents, which are very interesting. The frontispiece is a speaking likeness of the indefatigable President of the Society, Mr. G. Schneider, better known to English gardeners as the genial, versatile, and courteous Frenchman who so admirably presides over the Fern department in Messrs. J. Veitch & Sons' Chelsea nursery. The Hon. Secretary, Mons. Louis Gentil, has written in a graceful, pleasing style of Mr. Schneider's life and work, paying thoroughly deserved compliments to the author of "The Book of Choice Ferns." The general report by Mons. René Moser tells of good work well done, and looks hopefully to the future. Reports are given of the various meetings that have been held during the year, while Messrs. L. Pynaert and L. Gentil in collaboration have written an extremely interesting account of Messrs. J. Veitch & Sons' (Ltd.) various nurseries. The bulletin is entirely satisfactory, and we wish the Society increased success and prosperity in the future.

ROSE SHOW FIXTURES FOR 1897.

- June 10th (Thursday).—Ryde.
 „ 18th (Friday).—Portsmouth (N.R.S.).
 „ 24th (Thursday).—Colchester.
 „ 26th (Saturday).—Windsor.
 „ 29th (Tuesday).—Canterbury, Sutton, and Westminster (R.H.S.).
 „ 30th (Wednesday).—Croydon, Ealing, and Reading.
 July 2nd (Friday).—Crystal Palace (N.R.S.).
 „ 7th (Wednesday).—Glasgow, Hanley,* Hitchin, Reigate, and Tunbridge Wells.
 „ 8th (Thursday).—Bath, Gloucester, Harrow, and Woodbridge.
 „ 15th (Thursday).—Norwich (N.R.S.) and Helensburgh.
 „ 22nd (Thursday).—Halifax and Trentham.
 „ 27th (Tuesday).—Tibshelf.

* A show lasting two days.

The above are the only dates that have as yet reached me. I shall be glad to insert in the next list, which will be issued early in May, any further fixtures that may be sent me, whether of Rose shows or of horticultural exhibitions where Roses form a leading feature.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

SPRING IN LONDON.

Go where you will, either in the heart or the environs of the great city, which annually is stretching its mighty arms further and further into the country, and you will find unmistakeable signs of spring. Battersea Park in the south-west, famous for its tropical gardening and spring bedding, is assuming an appearance both green and refreshing. Summer bedding is the principal feature at Battersea, and bulbous flowers are not grown in such large quantities as in other of the metropolitan parks. Moreover, classification is not aimed at to any appreciable extent, yet planted as mixtures Hyacinths and early Tulips make a showy effect.

At one point, encouraged by the sunlight, red and yellow Tulips occupying a number of beds look very pleasing at the time of writing, and these are surrounded by other narrow plantations of mixed Hyacinths and that showy Tulip *Keizers Kroon*. From another point one notices long lines of Hyacinths, which have been gay for some time past, and along the herbaceous borders little clumps of Tulips and Hyacinths seem to present themselves at every turning. Springing here and there out of the grass are clumps of Daffodils, and on seeing them any Daffodil lover would say, Why is not more of that done? Under such circumstances certainly the nodding Daff shows itself to great advantage, and on the grassy banks and broad stretches of turf which Battersea Park possesses one sees a picture that might be further beautified by the presence of an abundance of these charming flowers. Along the borders herbaceous plants are springing, and in the shrubberies one notices the showy flowers of *Pyrus japonica*, Flowering Currants, and yellow Forsythias. Grass is growing freely, and though the show of spring flowers is not unusually large, thousands of the inhabitants of this rapidly growing suburb daily pause to admire as they pass on foot or on wheels along the broad, firm drives and walks which in themselves are a feature in Battersea Park.

Right on the other side of the modern Babylon lies Victoria Park, the favourite playground and garden of the teeming population who eke out a likelihood amongst the busy surroundings of East London. The contrasts are truly striking. One minute you are in a narrow stuffy street, lined on either side with overcrowded habitations, and breathing an atmosphere which never seems to get clear. Out of the street and through the gates you find yourself seemingly in another world, for there the trees grow, the flowers bloom, and the birds sing, and for the time being you are oblivious of the strange vicissitudes of human life which lie all round you. In the street you would think signs of spring could never penetrate that locality; but in the Park a different aspect appears. Spring flowers are all aglow, green leaves are bursting forth, grass is springing, and one feels thankful that Nature so readily beautifies amid surroundings where beauty is unknown.

Spring bedding in Victoria Park is always a feature, and this year the display of bulbous flowers is quite up to the usual standard, though the recent cold weather has been the means of retarding their progress. The main portion of the flower beds are admirably situated in a conspicuous position near one of the main entrances. Here the flowers show to advantage their variety of delicate colours in the sunlight. Hyacinths, Tulips, and Daffodils are admirably blended, though among the former one can notice traces of the sharp frosts which have recently prevailed. To mention varieties is but to go over the same ground again, for all those of well tried merit are to be found there. Workmen as they pass homeward through the Park, and others who come out for recreation, pause to admire and pass opinions on the flowers individually and collectively. Conspicuous as are the bulbs at this point it by no means

exhausts the display, as at almost every turn you come across masses of Hyacinths and nodding Daffodils.

Wallflowers are opening and Polyanthus commencing to bloom, in spite of the attacks of the London house sparrow, who appears to have a special liking for these flowers. Shrubs of hardy floriferous nature are making known their presence in the display of bright blossoms, and everywhere, in spite of smoke and gloom, one sees the unmistakeable evidence of a bursting into new life. Improvements, too, are also apparent, and the winter has been spent in the formation of a broad firm carriage drive, which penetrates through a portion that hitherto was bare, and had a most uninviting appearance. Great tracks of bare ground on each side have been fenced in and sown with grass seeds, and what was once nothing better than a quagmire of mud will in time be transformed into a stretch of green turf unsurpassed in any park in the metropolis. These improvements testify to the energy of the superintendent and the efficiency of the staff, and one cannot speak too highly of the effort made to beautify a park that is such an unquestionable boon to this crowded locality.

A walk round many of the adjacent enclosures, such as the clean and admirably kept old and new gardens at Bethnal Green and other open spaces that a few years ago were nothing more than an eyesore is not without interest, as they are in a smaller way now bright with the flowers of the spring. The London County Council has so many of these pleasant enclosures—for they may be justly so called—that it would take too long to notify them; therefore we will turn to South London, where we find a park of quite a different character. The park at Peckham Rye is of recent construction, speaking comparatively, and has an air of rustic nature about it that one does not find elsewhere. One looks in vain for large plantations of Hyacinths and Tulips, as bedding is not the predominating feature, but the little Winter Aconite appears here to tell of spring, and later the Bluebell, the Forget-me-not, and wild Parsley present themselves in profusion under the shade of the overhanging trees. Then there are the Hawthorn bushes with their wreaths of pink and white blossoms all in prospect, and a long time to come wild flowers of the character named will follow each in close succession. The garden portion tells of skill and attention, and one notices alterations and improvements that have been made to advantage. Wallflowers are opening and hardy flowering shrubs are all aglow, while on the giant trees all round a canopy of leaves is rapidly appearing, which when complete will put a finish on the woodland appearance of Peckham.

Not far away the undulating surface of Brockwell Park is looking fresh in its mantle of bright green, and near the entrances this is relieved by plantations of spring flowers. The old walled-in garden in the centre, which always seems to contain something to give pleasure to the thousands who wander round its complication of walks, is not without its features of interest, even at this early season, and though perhaps the herbaceous and other old-fashioned flowers which bloom later are more in keeping with the place, yet the gems of the spring cannot fail to attract admiration. Turning to Southwark Park, we find a display of bulbous flowers which is evidently appreciated by the inhabitants of that crowded locality. Hyacinths, Tulips, and Daffodils make up the show, the varieties of course being similar to those in other parks.

Across the great city once more to Finsbury, the well-known park of North London. Here again we find abundant signs of spring in the profusion of bulbous flowers, the bursting vegetation along shrubbery and border, and the increasing verdant appearance of the lawns. As in all these public playgrounds the same kinds of bulbs are used for the spring display, the difference alone lies in the methods of arrangement. Attention and good taste, however, are everywhere apparent, and it would hardly be fair to close these rambling recollections of a walk round the London parks without saying a word in favour of Messrs. J. Carter & Co., who supplied the whole of the bulbs by contract for the Royal parks. The task is no light one, and the general excellence of the flowers everywhere reflects great credit on the firm.—G. H. H.

LATE APPLES.—I was surprised to read the other day a note from a well-known southern gardener deprecating of Bramley's Seedling Apple as a standard variety. Perhaps this depreciation is due to the fact that the writer cultivates a somewhat sandy soil on gravel, and whilst some Apples do well on it Bramley's may prefer a stiffer compound. That it does thrive well on strong soil there can be no doubt, and perhaps likes a cooler temperature than the South furnishes. It would be well, in view of the note referred to, if some practical information could be obtained as to what soil and situation suits it best. When we hear of standards thriving luxuriantly and cropping heavily in an Osier bed in the Midlands it is natural to conclude that Bramley's is at once a deep rooter and a glutton for moisture. Lane's Prince Albert, Wellington, Alfriston, and other fine late varieties do well on the gravelly soil referred to. No doubt for such comparatively shallow soil the one named is the very best, because it is far from being a gross grower, and whilst a heavy cropper can be so readily fed from the surface. But we have undoubtedly in Prince Albert and Bramley's two of the finest average croppers and late keepers to be found. The former is better for gardens, the latter for orchards. Still it is desirable to learn if its average conduct on shallow soils, especially that because coming from the Midlands with such a high reputation we have been universally recommending wide planting. It is so important that in this matter there should be no mistakes.—A. D.

CROCUSES.

I WOULD revert to *Colchicum fasciculare*, which was mentioned in "Hardy Flower Notes" in the Journal of March 4th (page 176). Mr. Baker, with his uniform courtesy and kindness, lost no time in deciding the question submitted to him and in communicating with the writer. From his reply it appears that we are to regard the charming little *Colchicum* received as *C. fasciculare* as *C. bulbocodioides*, *M.B.* (*C. montanum*, *Linn.*, *ex parte*). Mr. Baker says that Boissier separates *fasciculare* as a species, but that he "cannot make more of it than a variety of *montanum*, distinguished by its very numerous flowers with very narrow segments." The writer is personally under an obligation to Mr. Baker not only for this statement but also for the information that this Meadow Saffron is found near Aleppo.

The same notes also contained a reference to some selected varieties of *Crocus Imperati*, a valuable, beautiful, and comparatively cheap early-flowering species of *Crocus* not nearly so well known as it ought to be. As may be supposed, these selected varieties are more highly priced, and they are again mentioned for the purpose of sparing the purses of some who might desire to possess them. The writer is indebted to the Rev. C. Wolley-Dod for the information that imported corms of this *Crocus* from Italy yield flowers varying not only in colour but in time of flowering. The purchase of some from an Italian firm entirely confirmed this, and not only are there flowers among this lot of several shades of the purplish colour which has few counterparts in its season among the genus, but also blooms of the varieties known as *longiflorus*. Some of these are quite as deep in colouring as one bought as *C. Imperati longiflorus purpureus*, and there are also late-blooming forms without the black stripes on the fawn colour of the exterior which are commonly present on this *Crocus*.

One bought as *C. Imperati longiflorus unicolor* is of this class, and could be duplicated among the imported flowers. These selections are useful for those who wish a clump of exactly the same appearance and blooming all at once. However, the difference in price is very great, as the typical *Imperati* can be bought in this country at from 2s. 6d. to 5s. 6d. per 100, and these varieties cost from 6d. to 9d. each, which makes them about 50s. to 75s. per 100. Even with a liberal discount for a quantity the difference is enormous. This is a *Crocus* which, like the well-known Dutch florists' varieties, should be planted in generous numbers. If planted in large clumps a quantity of *Crocus Imperati* of the mingled varieties would be very pleasing, giving flowers some seasons from New Year's day until well on in March.

Distinct enough, however, to plant by itself, and not dear at last year's price of about 6d. each, is *C. Imperati albidus*, sometimes offered as *C. I. albus* and *albiflorus*. This is almost pure white, but the interior has a few pale purple lines and the exterior is feathered with black. It is one of the coveted flowers with which the writer has had to exercise some patience, and upon which money was spent when it was higher in price than now, only to lose it before coming into flower. One can only hope that the better fortune recently experienced may be continued, and that in years to come we may still be rewarded by the sight of its pretty blooms spread out almost flat in the sun. This does not always come to cheer us in the first months of the year, but when it does come there are flowers to respond to its advances, flowers whose beauty is not to be measured by their size.—S. ARNOTT.

BOUVARDIAS FOR PROFIT.

"NOT much profit about Bouvardias," will be the ejaculation of some of my readers who have not succeeded in growing them satisfactorily, and they will be right. They are profitable under certain conditions only. If it is a question of sending so many boxes of cut flowers to Covent Garden, Manchester, Glasgow, Birmingham, Bristol, and other glutted centres, then there is little or no profit attached to the undertaking. My first season with Bouvardias on a large scale proved this. We were fairly successful in flowering the plants of good market varieties through the late autumn and winter months; but 3d. and 4d. per dozen sprays is not enough. It was not a "losing game," but other plants—Carnations for instance—would have paid us much better.

At 6d. per dozen sprays they pay very well, or say 6d. per plant the first year, and about 9d. the second season. Let me, however, warn beginners not to rush headlong into Bouvardia culture on the strength of my estimate, or they may meet with disappointment. It is not everyone who can grow them successfully; and another question is, Where are the best prices, or those stated, to be obtained? Not in any open market, or of many florists on a large scale, as these latter are only too well "posted up" as to the current prices at which they can get all flowers in

season. We sell to the smaller florists, more especially those doing a good trade with buttonhole bouquets and the like, and who are always glad to have boxes of suitable mixed flowers at reasonable prices. They readily pay 6d. per dozen, and get rid of fairly large quantities too. Bouvardias ought certainly to be cultivated by those who do a retail as well as wholesale trade, and in this case 1s., sometimes 1s. 6d. per dozen are made of the sprays or trusses.

We will first determine which are the varieties of Bouvardia best adapted to market culture and then enter into cultural details. The single flowering varieties are very pretty, and, as a rule, most floriferous. Unfortunately they do not last well, and are going out of favour accordingly. *B. Humboldti corymbiflora* is perhaps the most beautiful variety in cultivation. It belongs to the *jasminoides* type (fig. 72), and produces trusses of long tubular, pure white, sweet scented flowers freely in the autumn and up to midwinter. The habit is compact and good, and it transplants readily. This variety it is which we frequently see most effectively in wreaths, crosses, and bouquets. The flowers do not last long. Purity, a comparatively new form of *Humboldti*, possesses all its good qualities, and in addition the flower tubes are shorter and stronger. Mrs. Robert Green, a salmon pink variety with compact trusses, proves to be very popular with the ladies, and as the plant is of a robust, floriferous habit of growth a few of it may well be grown. President Cleveland is the best single scarlet I know, this having superseded elegans; while Vulcan, crimson, and Vreelandi, white tinged with pink, are also good.

The bulk of our plants, for reasons already hinted at, are of double flowering varieties. Alfred Neuner (fig. 72), white, and President Garfield, pink, are in most demand, and the best to grow extensively, while Victor Lemoine, scarlet, may well be given a trial. Whites, in the case of either single or double flowering varieties, should always predominate to the extent of three to one, as there are so many more ways in which these can be employed.

When I commenced Bouvardia culture for the markets six dozen well-grown plants set with flower trusses were purchased from a London firm in the autumn. The flowers sold from these paid for the plants, and we had a stock to propagate from. I may also be allowed to add that newly rooted plants in thumb pots will soon be offered by specialists at cheap rates, and these can be grown to a serviceable size by the autumn. After the plants have been cut over once it seldom pays a market grower to keep them on the chance of cutting a few late trusses. The space can be better employed, and the plants seldom produce good cuttings in quantity unless rested for a month or so. If the plants have been flowered in a temperature of 55° to 60° place them in cooler quarters for a time, but those flowered in a warm greenhouse need not be moved out unless the room they occupy is wanted for other purposes. In either case give much less water than previously, but they must have enough to keep the wood plump and the roots alive.

Supposing cuttings are desired a light pruning or a mere topping may follow this rest, and the plants early in February be transferred to a Cucumber house or other warm, moist quarters. syringing them frequently. They will quickly break strongly, and according as the shoots attain a length of 2 inches take them off with a heel of old wood attached; or, if a large number of cuttings are desired, the young shoots may be allowed to grow to a length of 3 to 4 inches and the tops be taken off and rooted, while more cuttings will be quickly produced on the reserved portions. For the cuttings fill well drained 5-inch pots with a mixture of fine loam and leaf soil in equal parts, with sharp sand added. Fix the cuttings firmly round the sides of these, and plunge the pots in a brisk bottom heat and close frame.

Kept uniformly moist, and carefully shaded from bright sunshine, roots should form in about three weeks, when they ought to be taken out of the frames and arranged on a staging or bed in heat. Top early, and when breaking afresh place the plants singly in 2½ inch pots, using soil as recommended for the cuttings. Young plants must still be kept growing in heat and a light position. Top them again when the shoots are 2 to 3 inches long, and soon after shift into 5-inch pots. For this, the final shift, use rough fibrous loam, or the best procurable, at the rate of two parts to one of leaf soil, with a little finely decayed manure, sand, and small charcoal added, and pot firmly. At this period of their growth they may be arranged on a bed of ashes in shallow pits or frames. They should be kept somewhat close for about a week, watered sparingly till fresh roots have formed, and be syringed once or twice daily. Bashy plants may be formed by topping the plants as often as forward enough, ceasing towards the middle of August.

Another good method of growing strong flowering plants is to top twice, and instead of persevering with this topping peg down the growths carefully to the soil. This causes strong sucker growths to spring up in the centre, and which, if left to their full length, branch and flower freely—a more continuous supply of bloom being had in this way.

We have yet to discuss the treatment of old plants, and allusion must also be made to the method of propagating by means of root cuttings. After all the cuttings needed have been obtained, the previous year's plants, and, if need be, the best of the older ones,

out of their pots, and shake or fork away the greater portion of the soil from the roots. It is then when root cuttings may be taken without injury to the plants, but it must be added they can be had much earlier from old plants that it is intended shall be

FIG. 72 —BOUVARDIAS.

should be taken in hand. If not already freely shortened back, cut them over again, much the same as a Fuchsia would be pruned. They quickly recommence top growth in a gentle moist heat, and when the shoots are one-eighth of an inch in length turn the plants

thrown away soon after flowering. Every short length of strong root with a few fibres attached may be dibbled thinly in pans or pots of soil as recommended for cuttings of young shoots, leaving only just the top or thicker end showing. Plunged in a brisk

bottom heat these root cuttings soon form shoots, and the plants may then be potted singly and treated similarly to the ordinary rooted cuttings.

After lightly trimming the remainder of the roots on the shaken-out plants, return them to pots just large enough to hold them comfortably, and place the plants in gentle heat for a few days. Directly root action has recommenced remove the plants to warm pits and frames, shifting them into pots two sizes larger before they become root-bound. Top sufficiently often to make them bushy.

Young and old plants alike must have abundance of air during the hottest part of the year, drawing the lights clear off during mild nights, and blocking them up over the plants, also shading lightly on bright hot days. They must have abundance of water when growing, and towards the autumn liquid manure also freely, though not in strong doses. House the plants before cold weather sets in. They will flower best in a warm greenhouse, or a temperature of from 50° to 55°, and may be introduced from rather cooler quarters in batches. Green and black fly, red spider, and thrips are all enemies to Bouvardias. Tobacco smoke or nicotine vapour will do good service in keeping down the aphides and thrips, and if ordinary syringing will not ward off red spider, introduce a handful of flowers of sulphur into the syringing water, and well coat the under side of the leaves with this.

Private gardeners will wonder why no allusion has been made to the plan of planting out Bouvardias during the summer. I am no stranger to this practice. It is not one to commend to the notice of market growers, labour-saving as the practice may be. They do well in pits, frames, or beds of moderately light, rich soil, and strong plants result. When these come to be lifted in the autumn they must have pots altogether too large to please market growers, who prefer handier sizes for their Bouvardias and other plants. Let those who prefer this method of culture give the readers of the *Journal of Horticulture* the benefit of their experience. Perhaps my views are incorrect, and there is "something in it" after all.—MARKET GROWER.

FRUIT GROWING ON CHALK.

AS those who have had practical experience are fully aware, the successful cultivation of fruit on soils in which chalk greatly preponderates is far from being an easy task; indeed, it may appropriately be described as uphill work from beginning to end. Should the attempt be made to grow fruit in the ordinary way—i.e., planting a tree and expecting it to flourish without anything further than the customary training, pruning, and autumnal mulchings of decayed manure, signal failure in the majority of cases is almost certain to ensue. This, of course, applies to soils of the very worst description, and to such fruit trees as Apples, Pears, Plums, Apricots, Peaches, and Nectarines. With small fruits, such, for instance, as Gooseberries, Currants, and Strawberries, the case is somewhat different, owing to their being mostly of a surface-rooting habit; still even with these more than ordinary pains are needed to insure profitable and satisfactory results.

The foregoing, it must be admitted, is simply the gloomy side of the question. It must not for a moment be supposed that success is impossible, or that such a thing belongs only to soils of a more genial character than those with which we are now dealing. "Where there's a will there's a way," is an old adage, and one certainly which applies with a certain amount of force to fruit growing on chalk. It is astonishing what a person may accomplish if he only has the will, receives encouragement, and determines not to be conquered in the struggle. That fruit trees may be made to flourish on extremely chalky soils will not admit of any doubt, but to accomplish this I must confess is a somewhat costly and laborious process. The last course to adopt where failure has hitherto been the only result is to make a fresh start and plant only young trees, say two or three years old, not more than four certainly. Previous to planting, trench the ground to a depth of 18 inches, and as the work proceeds work in a liberal dressing of well-decomposed manure and any decayed vegetable matter there may be from the refuse heap. Ashes from the burning of prunings and other rubbish may also be advantageously employed in the same way.

Young trees invariably thrive well the first two or three years after being planted; but suffer them to remain longer without any further proceedings being taken, and the penalty incurred will make itself only too plainly visible. Yellow, sickly-looking leaves, which are barely able to withstand the summer's sun, and weak spindly growth are the inevitable results of such a system. To avoid this state of things, and to produce a better, the person immediately responsible for the well-being of the trees should make up his mind to resort to that which, under the circumstances, is the only safe remedy—namely, lifting and replanting the trees periodically, say once in three years. By adopting this practice the roots are prevented gaining a firm hold of the subsoil, which is the cause of so much canker and decay, as it also is of many trees dying prematurely, and of fruit of an inferior quality. Wherever this periodical lifting system is adopted, the trees not growing on walls or as espaliers must of necessity be treated either as pyramids or bushes.

Grown in this way they become, as regards lifting and replanting, manageable for a number of years, and certainly far more than trees which have been unattended. The above applies to Apples, Pears, Plums, and Cherries, also Apricots on walls.

With Peaches and Nectarines unquestionably the best plan is to make and prepare a special border for them, take out the soil 2 feet deep, concrete and drain the bottom, and at a distance of 4 feet from the wall on which the trees are to be grown and parallel to it build a 4½-inch wall of either concrete or brickwork. Now we have to prepare the material for the border. Procure the best turfy soil obtainable in the locality; mix the same with the top soil taken from the border, in proportion of one load of the latter to two of the former; give a fair sprinkling of brick and mortar rubbish, and if the turf is only of an ordinary quality add a little decomposed manure. With this to grow in, and the necessary attention as to training, pruning, watering, and mulching, there need be no apprehension as to what the ultimate result will be.—E. C.

SALVIA GESNERÆFLORA.

AMONGST the many attractive and useful plants adapted for the spring decoration of the conservatory is this old and somewhat neglected plant, which, I imagine, was more recognised upwards of a quarter of a century ago than it is now. Why it should be neglected is a matter for some amount of wonder considering its comparatively easy culture, freedom from the attacks of insects or other disease, and not requiring the protection of glass during the summer and early autumn months. It may be remarked that the foregoing attributes are more or less shared by several other species of this numerously represented genus, which are recognised for their useful decorative value under glass, whilst that unique rich blue coloured species, *S. patens*, introduced from Mexico nearly seventy years ago, is still unsurpassed for richness, besides being equally appropriate both to the greenhouse and flower garden.

It is, however, to *Salvia gesneræflora* that I more particularly desire to draw attention, especially as to its suitability for growing into large specimens for the decoration of the conservatory during the months of March and April, when its long racemes of brilliant scarlet flowers are so acceptable at a time when red flowers are not very plentiful. It is bordering on twenty years since I last had the pleasure of cultivating it, and for many years previously several fine standard as well as pyramidal shaped specimens were in my charge. Some of these included the largest I ever knew, and some little idea may be formed of their size from the knowledge that the stems of a few of the finest of the standards varied from 2 to 4 feet in height and 6 or 8 inches in circumference, with heads measuring when in full bloom several feet in diameter. Of course, it will be conjectured that it was a matter of several years in their cultivation before the specimens in question attained the size indicated.

That their culture was of the simplest character may be inferred when I remark that for several years subsequent to the attainment of their full stature it was the usual practice to prune them hard back as soon as the branches had become ripened after the flowering period. When the new growths had become a few inches long the plants were turned out of the pots and the mass of roots reduced, returning them into the same pots with a substantial compost of turfy loam, old Mushroom bed refuse, and leaf soil, with a little sand, firmly rammed around the ball of roots. When all danger of frosts was over they were plunged up to the rim of the pots in a sunny border, and no further care taken of them, except the necessary waterings and occasional doses of weak liquid manure, until towards the end of September, when they were removed into a Peach house or other structure prior to consignment to the conservatory at any time during the winter, as even when not in bloom the noble appearance of the plants in the form indicated afforded pleasing variety to the other inmates.

It is somewhat of an anomaly that this genus of useful decorative plants should have been comparatively neglected, seeing that several of them possess also the faculty of flowering during the duller part of the year, and of these especial mention may be made of such as for autumn use the well-known old *S. splendens*, supplanted by its form *Bruanti*, and this latter by *splendens grandiflora*, a splendid scarlet-coloured and close-habited variety, a fine specimen of which was exhibited at the Drill Hall last autumn, from the gardens of Sir Trevor Lawrence, when it was awarded a certificate of merit. Next to the foregoing comes *S. Heeri*, a magnificent bloomer, and one of the best to last in a cut state without dropping its flowers. *Salvias*, in general, are not good subjects for lasting in a cut state.

Another variety, *S. rutilans*, deserves mention as a beautiful flowering winter species. It is popularly called the Pineapple-scented *Salvia*. Its crimson flowers are produced in long slender spikes, in the way of the well-known *S. coccinea*. It is a continuous flowerer, which greatly prolongs the beauty of the plant. *S. Betheli* also claims attention for its rosy-pink flowers and floriferous habit, whilst amongst the blue-coloured section *S. Pitcheri* merits distinction, and is most effective in association with some of the white-flowered *Chrysanthemums*. Being herbaceous in character it is easily increased by division or by cuttings made of the young growths in spring. *S. Butcheri* is said to be the best blue-coloured variety for autumn use; it is of dwarf habit. Several others of this interesting and invaluable family might be enumerated for the purpose in question, but the foregoing are amongst the foremost worthy of special notice.—W. G.

NOTES BY THE WAY.

THE movement on the Continent appears to be still spreading, and it may not be long before we have the gratification of recording that Chrysanthemum Societies have been established in Portugal, in Spain, and in Italy. In the early part of the year a meeting was held in Amsterdam of several Dutch nurserymen, with the result that a Chrysanthemum club was started, 110 members joining at the first meeting. We await with no small degree of interest further particulars, as the President and Secretary are well known to us as ardent "Mummers" for some years past.

Concerning the alphabetical arrangement of Chrysanthemum names for catalogue purposes, a subject that has occupied much time and attention, and which M. O. de Meulenaere so well set the example in his excellent catalogues of 1894 and 1895, M. Couillard, the registrar of the French N.C.S. contributes to "Le Chrysanthème" for April a lengthy article, in which several weak points in the system are referred to, and an invitation extended to all who are interested in the subject to consider the question in all its phases, so that it may be fully discussed at the Orleans Conference next November.

It will be remembered that the alphabetical list in the Jubilee edition of the N.C.S. catalogue is based upon M. de Meulenaere's system, but there are minor points in which differences are likely to arise. M. Couillard rightly considers that a common understanding should be come to, so that English, Belgian, and French catalogues, official and otherwise, should agree. In the Jubilee catalogue the principal noun is taken as the word under which the variety should be catalogued; but in a name like *Reiné des Abeilles*, *Ré d'Italia*, or *Queen of England*, differences of opinion may abound as to which is the principal noun, and especially where the catalogue is dealing with a foreign name. M. Couillard, as a Frenchman, is probably feeling what some of us as Englishmen have long ago felt. I believe some of our English Chrysanthemum growers will be invited to attend the Conference, so that any intending to do have plenty of time to consider any suggestions that they may wish to make.

Personally I think the great majority of English exhibitors are indifferent to the question, but they are not so in regard to the length of the names, nor to their foreign appearance. Of course we cannot expect French growers who know no English to name their varieties with plain easy English names, and so long as we are dependent on the foreigner for so large a number of our novelties so long will this inconvenience exist. And it must not be forgotten that we are not the only purchasers to be considered. Looking over the new lists I notice several curiosities of nomenclature that may cause trouble. Such, for instance, as *La Rhune* (not *Le Rhône*), *Montagne d'Oo*, *Premier Congrès de la S.F.D.C.*, *Naissance de la S.F.D.C.*, *Figueris*, *Noëly*, *La Faridondaire*, *Hortulanus J. K. Budde*, *S. M. l'Imperatrice Marie F.*, and *Madame la Comtesse Melchior du Chaffaut*; but on the whole we seem to be improving, and many of these phantoms only frighten us in the spring, for when autumn comes round we inquire sometimes for them, and echo answers, Where?

In the recently published Bulletin of the French Horticultural Society are two articles on the Chrysanthemum, which show that our young French friends during their temporary stay are on the look-out for anything of horticultural interest. One is called the "Royal Aquarium Chrysanthemum Show," and the other, "Chrysanthemums at Rochford's Nursery," the latter being accompanied with a list of varieties grown there.

In a New Zealand schedule of a Chrysanthemum Show, to be held this month, I see it is to be held in the Society's large marquee. Oh! happy New Zealanders! The plants are grown out of doors, and only covered with calico or some light covering to keep the rain off, and the feast of flowers is held in a marquee. I am wondering what an Aquarium Show would be like next November if held in a marquee, the Society's or otherwise. This, however, is in the North Island; further South, I am told, the cultivation and exhibition of the flower more nearly approach English methods.—C. H. P.

AS OF A DREAM.

WHEN "A. D." hoisted me on to my "Memorials of Planting" I little thought that their advent would appear in the same pages that chronicled the death of our dear old friend, Dr. Hogg, though it seems impolitic in me to write him "old," as being his senior. The observation of Mr. G. Abbey, on page 249, where, to my great surprise, he says, "I have only seen him twice," brings back to my mind "a red letter day."

Twenty years had expired since I began sending "copy" to the "Cottage Gardener," which first began to toddle at Winchester, and then when it was strong enough ran off to Fleet Street, where I had occasion to call for the first time to see Mr. Johnson and the Doctor. They were together in the room. Upon learning who I was out rushed the Doctor, who literally hauled me in to Mr. Johnson. Those who are alive and

knew them both can picture in their minds the sort of reception I received. It was "really Upwards and Onwards." After some time of talk by the trio the Doctor said, "Suppose we run down to Greenwich and have a little dinner?" "Agreed," said Mr. Johnson, and off we went there and then, two editors and he of Woodstock to the Temple Pier, where the prow of the boat pointed to the way we should float. Never was whitebait, &c., &c., more enjoyed, or laughter pealed forth more heartily than during that "little dinner." Well, "there is another and a better world."

I must now hark back. I left you last at page 226, in 1837. Early in the spring of that year I visited my native home. Col. Rushbrooke, with his family, had about 1830 gone to reside in France for a term. The Colonel on his return brought home grafts—Court Pendu Plat, Mère de Ménage, and other famous foreign Apples. The Colonel was a horticulturist and a member of the Royal Botanic Society, Regent's Park. I did not let my opportunity slip—for the grafts had grown into flourishing young trees—to beg of Mr. Wigg scions to take back with me to Shropshire. I knew of a nice lot of young Crab stocks growing in a cottage garden at the "Hope," and my scions were quickly whip grafted—every one took, and did well.

James Hardwick, our village carpenter, was a capital tutor to me in grafting, a man who was much employed then by Mr. Andrew Knight, when he had grafting to be done. Saddle and cleft grafting were his usual modes; in cleft more particularly he was a proficient. I send you knife he used*; I have two, so I will make you a present of the instrument as a curiosity. The blades were made at Shrewsbury; the handle and fastening, as you may shrewdly guess, were his own handy-work. Good old James—he stood 6 foot at least, was lanky withal, and had an immense Roman nose, of which he made good use in his articulation. He posed as a man of taste, and judgment to boot. Upon my once questioning him, "why he had not sang in the church choir lately," with an habitual shrug of his shoulders he answered, "If we are to sing, let's sing; but if we are to shout, let's shout." I knew this to be rather a side slap at Jones, so to try and smooth the troubled waters I said, "Oh, but Hardwick, the Scriptures do not forbid us to shout; and besides, if the choir did not raise their voices, nothing could be heard but the music." "Music!" Another shrug. We rejoiced in a base (let the spelling stand, Mr. Editor)—a *base* viol, a fiddle, an oboe, a clarinet, an old copper French horn, and a flute, the latter often producing more blow than melody. Nevertheless, the whole thing was hearty, and Hardwick relented. Mr. St. John used vicariously to call him "the stork," from the peculiarity of his carriage, and his resemblance to that stalking bird. He was an excellent carpenter, however—constructed all our aviaries and hen houses, and a universal help for me during my long residence in Salop. *Requiescat in pace.*

Now for a change. During an interval from planting, I will, if you think fit, relate a circumstance of "felling." On the margin of the churchyard in the foreground of the sketch previously sent there grew six very large Elm trees. They had for many years passed their best limit, and after the manner of their ilk had become very unsafe. Frequently a large bough would come crash down amongst the tombs and gravestones, or across the road, threatening expense to the vicar, or danger to wayfarers. Our factotum's health had given way, and Richard James had now taken a circumscribed place of William Jones. But James was never Jones. I remember once telling him that I would almost as soon trust a cow in the garden as himself, at which he was mighty indignant, and begged me to remember that he had lived with "Yarl Powis at Walcot." I found out afterwards that his employment with the Earl of Powis was the care of a brace of mules. However, James had been employed by Sir William Rouse Boughton and other gentlemen in the neighbourhood, a good deal in the woods, and could fell a tree to a nicety, so I felt the casting of these churchyard trees to be safe under his control.

All went well till the fourth tree was ready for a few final strokes of James' axe, when the rope attached to the upper part of this, the largest Elm, slipped off. The tree was "tottering;" the men were too heavy to undertake the risk of mounting to readjust the rope, but unless it was done the tree, with nothing to guide it, might fall prostrate, smashing amongst the gravestones, and its top limbs go crash through the new south-east window that Mr. St. John had so long been endeavouring to get placed there. There was no time for discrimination, the generalship seemed to devolve at once on me, and the fighting part as well. "Now, James, tie the spare rope to the end of the long ladder, and you, Penny, and young Williams, raise it whilst I 'butt.' Wind this handkerchief round my waist, and secure the rope to it with a bow. Now all hold to the rope attached to the top of the ladder to prevent it bearing too heavily against the bole of the tree, and up I go to try my 'prentice hand at slinging and tying a woodman's knot." Done! and down I slipped on the ladder, which was a familiar exercise. "Down with it; and Penny and Williams make the rope all taut—quick! James, you know all the rest." So with a few strokes of his axe he caused the monster to be thrown on to the bank exactly where it was wanted.

* The knife is a novelty, admirably adapted for its purpose, and will be preserved; blade nearly one-eighth of an inch thick at the back, 13 inch wide, and 4 inches long; handle octagonal, slightly thickening to the butt, where it is 4½ inches in circumference, 5½ inches long; attachment of the blade to the handle ingenious and effective. Evidently James Hardwick liked a good grip for making his "clefts," and he had one. The knife will be handy for opening boxes of fruit and other produce, the lids of which are not infrequently secured with 3-inch French nails. We are much obliged to our vivacious octogenarian (can it be?) and shall hope to meet him at Shrewsbury.

to lie. "Oh! it was a nervous quarter of an hour. But the rope was made secure enough on the two remaining trees, you may depend."

My next planting exploit took place upon the vicarage lawn—six dwarf Pear trees in 1838, in commemoration of Her Majesty's coronation year; and next, in 1840, Hardwick and myself transplanted the grafted trees from the "Hope" into the vicarage grounds, in commemoration of the Queen's marriage year; of course, without thinking that I should ever live to record their history at this time of day; and they may not, for all that I know, be even growing there now. At any rate, I left them flourishing in 1848. I have not visited Stanton Lacey since, and could now in all probability stroll through the village without being recognised. I fear I could do so even where I was born. I am harbouring a wish that I may be able to visit the great show at Shrewsbury in the autumn and take Stanton Lacey on my way thither, to see how, or if any of my commemorations remain to tell me their tale.—ROBERT FENN.

(To be continued.)

COLONEL TREVOR CLARKE.

THIS ardent horticulturist and excellent man passed over to the great majority at Axminster on the 11th inst., in his eighty-fourth year. The event recalls impressions of a very pleasant visit to his ancestral home, Welton Place, Daventry, Northamptonshire, at his special invitation, and as being associated with his esteemed old friend Dr. Hogg. The cordiality of the reception shown by the deceased gentleman to a working gardener marks the kindred spirit that knits together those engaged in horticultural pursuits.

Colonel Trevor Clarke had a profound respect for "good gardeners." His references to Mr. Barron, then Superintendent of the Royal Horticultural Society's Garden at Chiswick, Mr. R. Gilbert, and other practical gardeners of the past and the present, showed the foremost place cultivation and cultivators had in his estimation. Like the real gardener the Colonel himself was he first led the way to the kitchen garden, for no one knew better than he the importance of a full and successional supply of first-class vegetables and fruits, and he recognised the value of a good understanding between the worker in the garden and the presider at the dining table.

On my remarking that the somewhat heavy and red nature of the land at Welton Place was largely responsible for the excellence of the crops his retort was, "Good land often gives that to a gardener to which he would not otherwise be entitled, but even good land requires a good cultivator to take advantage of its stores." Trees—grand specimens of both deciduous and evergreen, indigenous and exotic—attested the sound staple on which they grew, as did the rich green sward of the lawn and the park land. The white Water Lily, the choicest British aquatic plant, admitted no rival in the lake, but crowded it with its luxuriant growth of green and reddish purple tinted leaves and pure, starlike fragrant flowers. So dense was the mass of these Lilies, the result of a rich sediment, that even the swans were unable to force their way through. As I admired the beauty of the scene and surroundings, the Colonel remarked, "Dr. Hogg was enraptured by the sight of the trees, and enchanted with the wilderness and its Swiss cottage." Then there was a sudden pause, for which I could not account, but afterwards learned from the butler (Mr. Nunn) that the wilderness and Swiss cottage were the work and delight of the Colonel's late wife, and that they had suffered in maintenance, the result mainly of agricultural depression.

On nearing the glass structures the Colonel's quaint humour and geniality returned in full force, and referring to Mr. Burbidge and his "Cultivated Plants," waxed eloquent and enthusiastic over his own hybridising work. He referred also to the importance of "selection," of which as an outcome we have Major Clarke's Solid Red Celery, still unsurpassed in the combined properties of useful size, crispness, juiciness, and flavour. As a result of his hybridising we have Begonia weltoniensis, one of the most useful of window and decorative plants; and Mr. Burbidge gives a list of over thirty hybrid Begonias raised by Colonel Clarke. Still on the same theme, reference was made to his endeavours to produce improved varieties of cotton. This entailed a long and exhaustive investigation into the history of the genus *Gossypium*. In connection with this work the Colonel expressed his great obligations to the Royal Horticultural Society, and praised the assistance rendered him by Mr. Barron. The cotton plants were shown me, the best varieties being then cherished by their raiser, also many other rare and valuable plants.

Butterfly Orchids, *Phalænopsis* species, were grown in quantities, and thrived like weeds over open tanks, and perfectly free from "spot." Bulbous plants seemed particular favourites, and rare ones, difficult to flower, flourished, for their owner was in every sense a cultivator—a practical as well as a scientific, gardener. *Monstera deliciosa*, planted at the foot of erectly placed tree holes, sent their long aerial roots into the open tanks of water at their foot, and bore grand leaves, with the finest spikes of fruit I have ever seen. Outdoor plants, especially herbaceous and alpine, were in strong force, the Colonel giving his attention to something of almost everything.

At the time of my visit the Tobacco-growing fever in England had passed its height, but the Colonel had been smitten, and not only grew the weed, but cured and prepared it for use in the form of pigtail, twist, rough cut and shag, cigar or cigarette, and in all colours—black, brown, and golden, with all strengths—mild, medium, and strong. The various brands of the Colonel's growth and manufacture were tried, but

all of them proved the masters of even seasoned smokers, and the subject was changed, the Colonel launching out into the depths of chemistry.

Colonel Trevor Clarke was a gentleman of many parts, not the least of these a chemist. Things liquid and solid were brought out of cabinets and explained. The Colonel made his own superphosphate by reducing the bones of the house with wood ashes from the hall fire and brick oven; also a phospho-potassic manure, with lime and other substances thrown in. Nitrogen and mineral matter was had from soot; while sewage was made sweet and eminently nutritious to crops by the use of sulphate of iron. The Colonel was an excellent botanist, an entomologist of considerable repute, a cultivator, experimenter, hybridiser, naturalist, and scientist. Colonel Trevor Clarke appeared not to count these as accomplishments, but as requirements for everyday use in the successful practice of horticulture.

There was no reference on his part to the gold medal awarded to him by the Cotton Supply Association of Manchester, and a special gift from the then Emperor of Russia, for the success of his experiments in hybridising and improving the varieties of cotton of the genus *Gossypium*. The grand old gardener—man of science, and fine old English gentleman—was as modest in respect of his own work as he was entertaining in conversation and liberal in diffusing information, yet, like other accomplished men, was ever seeking advice on anything of a perplexing nature to him. As an instance of this, he had a difficulty in getting his Melon plants to set their fruit. "They want something we are not giving them," remarked the Colonel. "Can you tell us what it is?" I made answer that they needed phosphorus and lime, for they were gorged, like the "hacca," with potash. Without saying anything more we passed on, but next morning I noticed that the Colonel had given them a dressing of superphosphate of lime. Months after that time I received a letter from him, saying that I was right. "The Melons did need phosphoric acid and lime. I gave them some of my superphosphate, and they have done splendidly. It acted promptly, both on the first and second crop."

The Colonel was a lover of music, and an accomplished player on the flute, the strains of which continued into the morning hours, and then came rest. Such is a reminiscence of my brief visit to Welton Place, in response to the invitation of its then gallant and generous-hearted owner.—G. ABBEY.

HOLLY HEDGES.

As this is the time of the year when many are thinking of forming hedges it may be of advantage to submit a few practical notes to the readers of our Journal. The best hedge plant is certainly the common green Holly, as it forms an impenetrable and ornamental fence, and when well established acts as a capital break to cold winds. The results of my experience here given have been bought at a great cost, for I have had hundreds of Hollies killed by injudicious or careless planting. The most important matter to be attended to is the purchasing of the Hollies. It is a wise plan to purchase the plants near home, and to see and examine them before buying.

The plants which are most suitable for moving have an abundance of fibrous roots; to such the soil adheres well. If the plants have long straggling roots from which the soil easily falls they will very likely be killed by removal. Nurserymen who grow Hollies extensively are careful to transplant them very often, so as to encourage the formation of fibres at the root. On stiff land Hollies cannot be grown satisfactorily for removal unless manure and peat are worked well into the soil. From the above remarks it will be seen that a judicious buyer will have several plants taken up so that he may examine the roots. Before the plants are lifted everything should be prepared so that they can be planted in the required positions without any delay, as it is most injurious to keep Hollies long out of the ground. One of the strongest points in my mode of procedure is to transplant quickly. I have had Hollies lifted in the morning, conveyed ninety miles by rail, and planted before night. There is the great danger of the roots becoming dry, which must be carefully avoided. If by accident the roots do become dry it is a wise plan to dip them into a bucket of water. In planting the soil should be trodden only moderately firm.

The best compost to work round the roots to assist the formation of fibres is a mixture of well decayed stable manure and bog or peat; this worked in liberal quantities into the soil as the work of planting proceeds will keep the roots moist, which is important, especially for young plants. I prefer the months of April or May for planting, but I am guided generally by the weather. I prefer moist weather for transplanting Hollies, no matter what time of the year it be.

In suburban districts many Holly hedges are planted in the front of villa gardens. I have seen hundreds of plants killed by injudicious planting in such positions. Villa gardens of the class I refer to have usually at the front a small stone wall about 3 feet high. The border is made to slope from the level ground to within a few inches of the top of the wall, and the Holly hedge is planted so that it shows well above the wall; it is thus exposed to the wind, and is in danger of becoming dry at the roots. In such a position the wonder is that the plants live at all. Any danger from this cause is easily avoided by allowing the soil to come only within a foot of the top of the wall. The appearance at the outset is not so striking, but in a few seasons the gardener so planting will be gratified by seeing a well-established hedge.

Immediately the hedge is planted the soil should be mulched with manure or tan to keep the roots moist. If very dry weather follow the

planting, the hedge will be benefited by a thorough watering. Persons who have established Holly hedges which are doing badly will find it a good plan to dig well to the roots, and work in a liberal quantity of good manure. If care be taken that the roots are not injured the hedge will be found to make a great improvement in a very short time. During severe weather Hollies sometimes suffer; it may, therefore, be of use to some to say that when a Holly loses its leaves through frost it is regarded as a good sign, for the plant will in all probability break out into growth when genial weather comes. The mode of procedure mentioned above I have found to be most successful, and the experience which I have pleasure in presenting to the readers of the Journal has been gained over a long period, and by many failures and many successes.—V.

MORÆAS.

At first sight most of the Moræas would be considered to be Irises, and to casual observation they present few distinguishing characteristics; but on close examination we at once find them differing from the true Irises by their bulb-like root, thus approaching the bulbous Irises (Xiphionites). On a further examination, however, it will be observed that the root of the Moræas is solid or corm-like, and not formed in layers as it is in the Xiphionites. The species can be grown in pots or planted out; but the former is preferable, light soil being employed, and providing good drainage. Large pots are not necessary; 3-inch or 5-inch suit them well, placing several bulbs in each. Supply water judiciously, but when growing or flowering they must not be allowed to become dry, and even in the resting period withholding water must not be carried beyond reason.

M. Sisyrinchium (fig. 73) is a beautiful species, a native of the South of Europe and the Mediterranean region, and has long been known as Spanish Nut, because it is said that in Spain the children eat the root as a nut, of which it is suggestive both in the form and the brownish colour. It was mentioned by the old writers Gerard and Parkinson, and has therefore been known in this country nearly 300 years. The flowers are very handsome, though fugitive, the larger perianth segments being bright deep blue marked with white and yellow in the centre, the other divisions of the perianth being also blue, but lighter in colour. The illustration depicts the chief floral characters, well showing the general form. The flowers are usually produced in the spring, about May.

Though a European species *M. Tenoreana* was not introduced into England until 1824. It is scarcely less beautiful than the one referred to in the preceding paragraph, though the flowers are smaller, but the colour is very rich. The divisions of the perianth are narrow, the upper half being deep blue, and the lower towards the centre yellow and white with a few dark spots. It flowers fully a month later than *M. Sisyrinchium*, and thus forms a welcome succession.

M. edulis was one of Loddige's introductions from the Cape of Good Hope to this country, but it is said to have been known in Holland for many years. It was originally found by Thunberg growing abundantly in the neighbourhood of Cape Town, chiefly in low positions and in sandy soil. The flowers vary in colour, but are mostly of a pinkish hue marked with blue and white, the divisions of the perianth being neatly rounded. One very pleasing characteristic the flowers possess—namely, a most agreeable though delicate fragrance.

Three other species that deserve growing are *M. ramosa*, with comparatively large flowers, bright yellow, with a dark blotch at the base of the petals; *M. ciliata*, with small bright red flowers, rounded petals, and a yellow centre blotch; and *M. papilionacea*, with bright orange coloured fragrant flowers, which are produced a little later than *M. Sisyrinchium*. These with the preceding form a good half dozen, and fairly represent the genus.—F. D.

THE WOOLLY APHIS, OR AMERICAN BLIGHT.

THIS insect has decidedly increased during the last few years, particularly in orchards and Apple plantations where the trees have been unpruned and neglected; and its action is most injurious. Young trees planted in infested orchards and plantations are frequently so injured by the woolly aphides carried to them by the wind and by the winged females that they die. Their bark being tender is easily pierced by the sharp beaks of the larvæ, and they cannot long withstand these attacks.

Apple growers often notice bunches of a woolly or cottony substance on the stems, branches, and twigs of Apple trees, especially upon scars and cracks where the bark has been injured, or where side shoots and branches have been cut off in an unworkmanlike manner, so that wet has collected and caused decay, and fissures have been formed which have increased in depth and width, while the edges of the outer layers of bark do not join, and a thin tissue covers the exposed parts. Upon examination the white substance on these will be found to consist of little groups of aphides in various stages, some of which are clothed with fine woolly coverings, and are actively engaged in piercing these denuded surfaces with their suckers and in feeding on the sap, thus causing an abnormal growth of tissue. Extravasation of sap occurs, giving rise to excrescences and warty growths, which afford food and shelter for the numerous generations of larvæ, and eventually the whole branch is affected and its vigour and fruitfulness materially impaired. The infestation spreads rapidly to other parts of the tree, and the smaller branches and fruit-bearing spurs are in time attacked. When the twigs and fruit-bearing spurs are attacked they are soon killed by

the action of the aphides. After an uninterrupted visitation of these insects it often happens that the infested tree dies or becomes useless.

The effect of this attack is sometimes attributed to "canker," but it is altogether different, and careful inspection will show that the woolly aphis is the sole author of the mischief. It spreads from branch to branch, from tree to tree, and from orchard to orchard unheeded, and unchecked, and it is sheltered and protected by the lichenous and mossy growths upon the trees and the thick interlacement of boughs and branches unpruned for generations. The woolly aphis is occasionally found upon Plum trees, especially where they are planted near Apple trees, as well as upon Elms.

The woolly aphis also infests and injures the roots of Apple trees and causes swellings and excrescences upon them. It has been suggested that the aphides merely go under the ground close to the roots for protection from cold; but the colonies found there were evidently

FIG. 73.—MORÆA SISYRINCHIUM.

feeding upon the roots. Besides, it is certain that they can bear great cold, as they have been seen flourishing under their woolly coverings in the cracks and crannies of the branches after 12° of frost.

The aphis belongs to the genus *Schizoneura* of the Aphididæ. It is quite distinct from another species of aphis found upon Apple trees, known as aphis mali, which lives upon the leaves and blossoms. The winged female, which brings forth living larvæ, is dark brown, having large wings with black veins; the cubital vein, as pointed out by Mr. Buckton, has a single furcation or fork, differing in this respect from other tribes of the Aphididæ. Towards the end of the summer, among the larvæ produced by the winged females, are wingless, egg-bearing females of a dirty yellow colour, without beaks or rostra, and therefore unable to feed. Only one very small, round, transparent egg is laid by each of these wingless females, and is deposited in the crevices of the bark. Propagation—the regular continuity of existence—is principally carried on, however, by the hibernating viviparous larvæ, which pass the winter wrapped in their woolly coats upon the trunks of the trees, on the branches and twigs as well as upon the roots. These wingless females are woolly, of a brown colour, and broad or squat in shape. The larvæ from these are at first rather lighter in colour, and after a time emit wreaths of woolly material from their dorsal pores and become completely covered, so that a group of them has the appearance of a piece of cotton wool. In their early stages the larvæ have enormously long beaks or rostra, bent underneath the body, and extending much beyond the extremities of the body, so that they appear to have tails when seen without a microscope.

There appears to be no visible difference between the generations of this insect that are found upon the branches and those on the roots of Apple trees.

METHODS OF PREVENTION AND REMEDIES.

Apple trees should be kept free from mossy and lichenous growths, which serve as shelters for woolly aphides, as well as for many other injurious insects. Lichens and mosses can be killed by throwing finely powdered lime over the trees during the winter, in foggy or damp weather, so that the lime adheres to the trees. This can be done by men with tin scoops, like flour scoops, fastened to the ends of long poles. Sulphate of iron dissolved in water, at the rate of 1 lb. to 1 gallon of water, sprayed over the trees in winter by means of a powerful garden engine, or hop washer, will kill lichens and mosses, and interfere much with the woolly aphids.

Young trees should be carefully and systematically pruned, so that their boughs do not intertwine, and plenty of air and light is admitted. Periodical search should be made for woolly aphides and other insects upon young trees. When the woolly aphid is discovered in wounds and scars on the stems and branches, which are often frequented by its colonies, these places should be treated in the late autumn or winter with a thick compound of softsoap and paraffin oil, mixed in the proportions of 3 gallons of paraffin to 1 lb. of softsoap and 25 gallons of water, worked into the cracks and scars with a stiff brush. Infested boughs and twigs should be syringed at the same period with a mixture of 5 or 6 lbs. of softsoap and 5 gallons of paraffin oil to 100 gallons of water. In mixing the paraffin washes the soap should be dissolved in hot water and the paraffin put in whilst it is hot, and the whole incorporated into a cream with a hand pump or syringe, working the liquid up and down. Cold water must then be added in proper proportions.

In old orchards and plantations in which pruning has been neglected boughs and branches crossing each other should be cut away judiciously, and daylight let in. Scars and deep fissures on the trunk and stems where woolly aphides congregate should be treated with freshly mixed limewash, having a little powdered sulphur in it, worked well in with a stiff brush. The thick softsoap and paraffin wash would be more efficacious, but it is somewhat expensive. For the infested branches, boughs, and twigs of large trees spraying with the softsoap and paraffin mixture should be adopted.

In orchards where trees are in regular lines horse hop washers may be used. In old orchards, where the trees stand irregularly, and in plantations with standards and bushes below, hand washers or garden engines with powerful pumps and long lengths of hose must be employed.

Where Apple trees are infested with woolly aphides on their stems and branches examination of their roots should also be made for infestation thereon, which is indicated by swellings upon the roots, and by the groups of woolly insects. The earth should be removed from the base of the trunk and from a few feet of the lateral roots. Limewash with sulphur brushed well in, or the thick paraffin wash, would be advantageous. Penning pigs close round infested orchard trees, or watering the roots with strong liquid manure, would make it unpleasant for the subterranean invaders. Kainit hoed in round the roots has been found efficacious in Canada.

Before Apple trees are planted their roots should be well soured in a tub containing fresh limewash and sulphur.

In Australia there are varieties of Apples said to be proof against the action of the woolly aphid by reason of their bark being hard and its tissues close, and so resisting the action of the beaks of the insects. These are the Northern Spy, an American Apple, and the Majetin, a Norfolk (England) variety, and Apples in Australia are now always worked upon these stocks. Mr. French, the Government Entomologist of Victoria, says, "Before the advent of these excellent blight-proof stocks, the Majetin and Northern Spy, it was exceedingly difficult to find in most orchards an Apple tree that was clean or in perfect health. Now with a little care and attention the fruit grower, as a rule, may snap his fingers at the American blight."—"Board of Agriculture, Leaflet No. 34.")

AMELANCHIER CANADENSIS.

DURING April one of the most conspicuous of the many hardy flowering plants is the one under notice. Varying much in size and habit it is well adapted for a variety of purposes, and being an easily managed plant it is almost certain to be a success. Some forms never grow into more than bushes a few feet high, while instances of others are recorded as having made trees 25 to 30 feet in height.

The tree forms in this country are usually met with from 15 to 20 feet in height, with short stems and bushy heads, resembling very much the head of a well-balanced Apple tree with pendulous branches. Bush forms are admirable for planting in beds or masses, and once planted in good soil they will take care of themselves for a number of years. Suckers (which are thrown up freely) grow in one season to 3 or 4 feet in length, and form graceful arching branches, which in April are wreathed with racemes 3 inches in length of pure white flowers.

Added to the value this North American introduction possesses as a spring flowering shrub it has the additional recommendation of being a most beautiful coloured foliage plant in autumn, the leaves changing to orange and red before falling. If plants of the dwarf growing forms are lifted in the autumn, potted, and placed in gentle heat in January, they will be found to make a welcome addition to the greenhouse or conservatory.—W. D.

LILY OF THE VALLEY, FORTIN VARIETY.

IMPROVED variations of that popular flower, the Lily of the Valley, cannot be said to be very numerous, certainly not in proportion to those of other favourites even less extensively grown than this. Some fine forms have, it is true, made their appearance from time to time, and have by degrees come into general cultivation.

All of these have either been grown by myself or have been under my close observation, and though they individually possess special qualities or recommendations, there is not one known to me that can rival the Fortin variety for some of the most important qualities. It is essentially a form of remarkable vigour, both leaves and flower spikes being of unusual size, very sturdy and tall. The spikes are from 9 inches to 12 inches long, with twelve to eighteen large pure white bells, and in some instances more have been noted. It is valuable for outdoor cultivation, and is also suitable for moderate forcing, but is not so well adapted for very early work.

The robust habit, rapid increase, large spikes and bells will render it a general favourite as its merits become known. Last year I saw a large plantation of the variety grown in sandy loam in the neighbourhood of Ampthill in Bedfordshire, which I am informed is the stock of Messrs. Laxton Bros., who are paying close attention to what is unquestionably an excellent variety. Recently flowers were exhibited in Bedford and greatly admired by the members of the local Horticultural Society.—OBSERVER.

[Specimens of this variety sent to us by Messrs. Laxton Bros., Bedford, were superb. The longest spike measured 15 inches and carried sixteen bells, of which the largest was $\frac{1}{2}$ -inch across, outside measurement. The several spikes averaged fifteen bells each.]

THE BRITISH CLIMATE.

THE Meteorological Office has issued a set of mean or average values for the chief meteorological elements, based upon records kept at a large number of stations scattered over the entire kingdom, and extending over a long series of years down to the end of 1895.

BAROMETRICAL PRESSURE.

The means are given for twenty-nine stations well distributed over the United Kingdom, show that over the year as a whole the barometer is highest in the extreme southern, and lowest in the extreme northern parts of the country. The same feature is, in fact, shown in every individual month excepting April, the difference between the readings in the two localities being greatest in the winter time. In April the conditions are somewhat abnormal, for while the barometer is still lowest in the north of Scotland, it is highest over the central parts of England.

On an average the barometer over the kingdom generally reaches its highest point in June, but on our south-west coasts it is almost equally high in September, while in the south-eastern parts of England the second place is claimed by February. The lowest barometrical pressures occur at various times of the year in the different districts. In the south of England April appears to be the month chiefly favoured, but in other parts of England the lowest readings occur either in October or November. In Ireland the barometer reaches its lowest point in November, while in Scotland the minimum occurs in December.

HUMIDITY.

The averages of the dry and wet bulb thermometers, which are also given for twenty-nine stations, supply us with information as to the relative humidity or degree of moisture in the air. As a rule, the atmosphere is driest either in May or June, the air being most humid in one or other of the winter months between November and February. Taking the year as a whole, the moistest locality in the United Kingdom is the Hebrides, these islands lying in the direct track of the two most common sets of cyclonic systems—viz., those which pass northwards along our western coasts, and those which skirt the north of Scotland on their way from the Atlantic to the Scandinavian peninsula.

TEMPERATURES.

The mean values relating to the maximum and minimum temperatures are singularly comprehensive, the number of stations employed being no fewer than seventy-four. Over the United Kingdom generally the highest maximum or day temperatures occur in July, the only exceptions being the Welsh coasts and the extreme southern parts of Ireland and England, where the greatest heat is registered a month later. The lowest day temperatures occur as a rule in January, but in many parts of Ireland and Scotland they are as low, or even lower, in December. The highest and lowest minimum or night temperatures are, as a rule, observed, like the maxima, in July or January. In portions of the west of Scotland, however, the lowest night readings occur in February, while at some stations on the shores of the Bristol Channel they are observed as late as March.

In the table the highest temperature quoted was in London, where the thermometer in August, 1876, rose to 96°, the reading at Cambridge at the same time being only 1° lower. In the Scilly Islands the thermometer in the same twenty-five years never rose above 75°, while at Summerville Head in the Shetlands it never went above 70°. The lowest reading shown in the table is one of 5° below zero at Loughborough in February, 1895. This, however, was several degrees higher than the temperatures recorded in many other parts of Great Britain during the long and severe frost which prevailed at that time.

RAINFALL.

The rainfall averages are given for seventy-two stations, and extend over the thirty years, 1866-1895. With one important exception the figures give a fair representation of the average fall over the United Kingdom. For the wettest locality of all—the English Lake district—no information is given; but another very wet district—viz., the West of Scotland, is fairly represented by such stations as Glencarron, Fort William, and Laudale on Loch Sunart. At Glencarron the average rainfall for the whole year is nearly 86 inches. In London the average is rather under 25 inches, while at Spurn Head, the driest place given in the table, the annual fall is less than 21 inches.

In the extreme south of England the driest month in the year is May or June, but in London and over the midland counties generally it is March, while in the north-east of England February has the least rain. Over Scotland, the north-west of England, and all but the extreme southern parts of Ireland, the driest month is April, though very little drier than May. The wettest month over England and Wales as a whole is October, but at some stations in the north and east of England the rains are heaviest in July. In the south of Scotland and over the central parts of Ireland July or August is the wettest month, while on our south-west coasts, including the south of Ireland and the Scilly Islands, as well as in the west and north of Scotland, the distinction is claimed by December or January.

SUNSHINE.

The averages of bright sunshine, which are given for forty-six stations, show that the brightest spot in the whole kingdom is Jersey, where the average duration of sunshine in the whole year is 1930 hours, or 44 per cent. of the possible. Next to this come many other English Channel stations, where from 1650 to 1750 hours are registered. In London we only get on an average 1240 hours of sunshine per year, or 28 per cent. of the possible amount. This is, however, better than Glasgow or Fort William, where they only get 25 per cent.

The sunniest month in the year is May, and afterwards June or August. In August the proportion of the possible amount is, as a rule, appreciably larger than in July, a fact which seems at present to admit of no ready explanation. The gloomiest month of all is, as a rule, December. In this month even the sunny Channel Islands do not get more than one-fourth of the possible duration. In London the ordinary allowance of sunshine in December is only 9 per cent. of the possible, and at Glasgow 8 per cent., while at Fort William it is as low as 6 per cent.—("Daily News.")

THE YOUNG GARDENERS' DOMAIN.

It is especially desired that all contributions intended for insertion in this column be addressed, till further notice, to the Editor, 8, Rose Hill Road, Wandsworth, London, S.W. There is a perceptible falling off in letters from probationers, and perhaps the "willow" has in some instances been found more attractive than the pen.

THE HORTUS SICCUS OR HERBARIUM.

(Concluded from page 324.)

THE ancient adage, that if a thing be worth doing at all it is worth doing well, applies to the preservation of plants for the herbarium as much as to any great and important work or business. Specimens that are no better than fragments of brown stick, or which seem mere effigies of plants cut out of thin brown paper, the flowers shrivelled and shrunk so as to be no longer recognised, the leaves crumpled and doubled up, everything confused and smashed together, such as one may sometimes see in collections, are altogether undeserving of the name. Nothing that is not dried in the best possible manner, its colours and configuration preserved as perfectly as the nature of the plant will admit, ought to be allowed a permanent place in the herbarium. The bad may be tolerated awhile in default of better, but the farther a specimen is from vivid and pleasing resemblance to the living thing, the speedier should be the endeavour to supersede it. Specimens from abroad that cannot be superseded, of course, I do not speak of. In the plants within reach, none but admirable representatives of their best features while alive should be considered worthy of a place.

Plants dry variously; some require not a moment's trouble, others demand patience. Grasses and their allies, most kinds of Ferns, plants that resemble Heather, Everlastings, the mature leaves of shrubs and trees, call for only the minimum of care. Those which try the patience, and can be managed only after considerable experience, are such as may be illustrated by citation of the Hyacinth.

To secure the best results obtain half a dozen pieces of stout mill-board cut to about 18 inches by 12 inches; then gather together a hundred old newspapers, and fold them neatly and to about the dimensions of the millboards; 4 or 5 yards of common white cotton wadding, a score of sheets of tissue paper, and as many of blotting paper, all cut to the same size, complete the requirements.

One of the boards serves for the foundation; on this spread a newspaper, then a piece of wadding, and upon this place the specimens intended to be dried. The cotton being soft every portion can be laid in a proper and natural way, including the petals of the flowers. Lay a newspaper over them, two or three if the specimens have thick stems, and so on, till all shall be deposited in the way of the first. If the specimens are sticky or hairy, or of a kind that the wadding seems likely to adhere to, then, before depositing them on it, introduce a half sheet of the tissue paper.

A heavy weight must be put on the top of all, sufficient to imbed the specimens in the wadding; then leave the whole to rest for twenty-four hours. All the papers must then be changed, dry ones being put in their place, and if the plant seems to throw off a very considerable amount of moisture, such as will render the wadding quite damp, change the wadding also. A second and even a third change is desirable at the end of two or three days or a week, and when this is made introduce the blotting-paper, pressing again till everything is perfectly flat and the specimens are absolutely dry.—C. W. M.

[We are obliged to our correspondent for the precise instructions he has given on this subject. The drying of specimens and their classification, as suggested last week, affords interesting and instructive occupation for young gardeners.]

FORCING FRENCH BEANS.

I AM surprised by the trouble "W. W." (page 301) takes, and the work he makes in French Bean forcing. It would be interesting to know what advantages, if any, accrue from the potting-on system. I think the practice adopted by my chief is preferable. We have more Beans, with a saving of time and labour, by sowing direct in the fruiting pots. We grow a quantity of specimen Chrysanthemums in 11-inch pots, in the vineries and Peach houses, and as these plants are cut down, and the houses started in January and onwards, we turn the soil out of the pots on the path, chop it up, pick out the old Chrysanthemum stools, add one-third of old Mushroom bed refuse, mix and return it to the pots, sowing sixteen Beans in each, and place them on the hot-water pipes until the plants are in rough leaf. We then stand them on the borders, 4 feet apart, where they make short, luxuriant, self-supporting growths, from 12 to 15 inches high, and a yard through the plants, without a trace of red spider. Treated in this way they make their growths before the Vine foliage becomes dense. We sow three dozen pots at intervals of three weeks, and gather about 2000 thick, fleshy Beans from the plants of each sowing. The two last sowings are made in April, these plants are grown in Peach houses, and require supports, as the growths come somewhat thin and elongated owing to the rising spring temperature, and the extra syringing required by the Peach trees in May. Care is taken not to overwater, but when the plants commence flowering liberal supplies are necessary. We cannot see any beneficial results from liquid manure, and have discontinued it.—STONE-WARRILOW.

[A brief narrative of successful practice, highly worthy of record here.]

DIPLADENIAS.

THE Dipladenia is a valuable stove climber, and also makes an effective specimen for exhibition, but the plants require much care in cultivation. Brisk heat is necessary, and they must at all times be shaded from the bright sunshine, admitting at the same time as much light as possible.

The Dipladenia should not be overpotted. Plants about eighteen to twenty months old, if they are in a good condition, require pots from 12 to 14 inches in diameter. With regard to the most suitable soils opinions differ. Where really good fibrous loam is obtainable it may be used for Dipladenias with an equal quantity of good peat, together with sufficient coarse sand and charcoal to keep the whole porous and sweet; but if loam is not in the best of condition avoid it by using more peat.

Dipladenias, if grown for exhibition purposes, are trained on a wire frame or "balloon;" but first the young growths must be trained up the rafters of the stove. When flower buds appear the growths are with great care taken down and tied to the trellis, always bearing in mind to have a good head and front to the plant, tying the weaker shoots to the back.

In the growing season the most suitable temperatures range between 65° and 75° by night, rising to 80° and 85° by day, with a moist atmosphere, obtained by well damping down the stages or ashes, which the pots may be standing on.

Dipladenias require a moderate supply of water during the growing season, but as soon as they have finished flowering they should be removed to a cooler house, fully exposed to the light, to well ripen the wood, after which they require very little water, and must soon be returned to the stove.

With regard to insect pests, I think the most injurious is the mealy bug, which should be removed with lukewarm water and a soft sponge. Softsoap is often used with the warm water to well clean the foliage.

There are many Dipladenias in cultivation; but I think the most suitable for exhibition purposes are *amabilis*, *amoena*, *hybrida*, *profusa*, *Ellioti*, and the king of them all *Brearleyana*.—W. LOCK.

[Our correspondent sends us a photograph of a splendidly grown plant, but unfortunately not clear enough for satisfactory reproduction.]

CAMDEN CYCLES.—Gardener cyclists within the metropolitan area have not had a very bright chance of following their hobby of late, but the time will come when there may be twenty-four consecutive hours of fine weather. Then must the rider mount and away to some brother craftsman to see what there is to see, and talk what there is to talk. To the one who does a fair amount of visiting of this nature the bicycle is a very great boon, and those whose mount is getting the worse for wear or out of date will do well to consult the catalogues of the British Cycle Co., 42, High Street, Camden Town, the makers of the high grade "Camden" bicycles, ere finally placing their order.

HARDY FRUIT GARDEN.

Disbudding Superfluous Growths of Fruit Trees.—Disbudding is an operation which requires to be carried out more or less with all trained fruit trees. It is, however, with stone fruit trees on walls that the practice of disbudding is chiefly concerned. Apricots, Peaches, and Nectarines are usually the most freely attended to under good management. Plums, Cherries, Apples, and Pears are not generally so dependent on this attention, though they are benefited by the removal of some growths. This is especially so when the trees are young and in the course of formation into special shapes. The main object of this operation is to regulate growth and prevent overcrowding. Energy is also conserved, and led into a limited number of channels, consisting of well-placed growths fully exposed to light, as it is by these means alone that the best success can be achieved with all kinds of hardy fruit trees.

Method of Disbudding.—The operation consists in rubbing or breaking out the growths not required when they are an inch or two long. After they have attained to a much greater length they cannot be removed without cutting. This is frequently necessary in the later stages of disbudding, or when the work has been left beyond the proper time. The tissues at the base of the shoot become somewhat thickened and strengthened, hence the importance of early attention. Disbudding should always be gradually carried out, so as to occasion no check. A little at a time and frequently is the best rule to follow. The weather has some influence on the work. More shoots may be removed in active growing weather than in cold periods.

Apricots.—As soon as a number of growths have advanced sufficiently look over the trees and rub off the ill-placed shoots first. The whole of such between the branch and the wall may be dispensed with, also those on the lower side, reserving a selection emanating from the upper sides for laying in as successional wood for fruiting. Apricots form a number of natural spurs, which may be permanently retained. Some of the foreright shoots, which have to be removed to prevent overcrowding, instead of being cut out entirely may be shortened at the third leaf to form spurs. The leading growth of the fruiting shoot must be left, eventually stopping it at the third leaf. This growth is required to draw sap to the fruit. One of the well-placed shoots at the base retain to take the place of the fruiting shoot in autumn. Other suitable growths in various parts of the trees may be reserved if necessary for filling unoccupied space, or replacing a weak, ill-nourished branch.

Peaches and Nectarines.—In the early spring management of these trees early but light and frequent disbudding forms no inconsiderable part. Young and vigorous trees need constant attention to prevent the extension of shoots not suitably placed, first, for forming the foundation or outline; second, the distribution equally and regularly of fruiting shoots. As Peaches and Nectarines do not form spurs so naturally or freely as Apricots fruit is borne principally on young well ripened shoots of the previous year. Therefore a sufficiency of these should be laid in. The process is the same as with Apricots. Ill-placed growths are in all cases removed first. Commence disbudding at the top of the trees.

Reserve the leading growth on the fruiting shoot, stopping it later on. Without some foliage above or near the fruit the latter cannot be nourished. A full supply of successional shoots must be retained, one at the base of each fruiting branch, laying it in in the desired direction as it extends in growth. In some cases two such growths may be encouraged, but this must be regulated by the available room. Crowding during growth is pernicious. The leaves should have full opportunity of carrying on the work of assimilation, and thus be enabled to store up material in the buds for the following year's use. Strong and sappy growths starting from old wood are, as a rule, not required, and should be rubbed off before they gain strength, and utilise energy which is better distributed throughout the trees.

Plums and Cherries.—Trees showing indications of producing too many shoots eventually, for which there will be no room, ought to receive a little systematic disbudding so as to reduce the number. Choose for removal those which are weak and ill placed, reserving the best either for extensions of young growths for laying in at full length, or shortening them early at the third good leaf to form spurs. Both methods may be adopted with Plums and Sweet Cherries trained on walls, but the young wood may not produce fruit until the second or third year. Short and stubby natural spurs must be retained wherever possible.

Apples and Pears.—Disbudding is specially beneficial where there is a large amount of growth produced among the spurs. Such growths occupy valuable space, and prevent light and air reaching permanently fruitful spurs. Well established fruitful trees do not produce superfluous shoots that need removal by disbudding quite so readily. Young trees both on walls and in the open may usually be improved by a little judicious disbudding, so as to assist the regular disposal of the growths and secure shapely forms of trees.

FRUIT FORCING.

Peaches and Nectarines.—*Earliest Forced House*—Cease syringing the very early varieties—Alexander, Waterloo, Early Beatrice, and Early Louise Peaches; Cardinal, Advance, and Early Rivers Nectarines—as soon as the fruits give indications of ripening. Do not supply water excessively at the roots, yet maintain the soil in a moist healthy condition, and afford moderate air moisture by damping the paths and borders occasionally. Hale's Early, Dr. Hogg, Dymond, Stirling Castle, Crimson Galande, and Royal George Peaches, with Lord Napier, Stanwick Elruge, Humboldt, and Dryden Nectarines will need liberal supplies of water, and perhaps nourishment to swell their fruits well. Where the crop is too heavy thin the fruits, for it is not the flesh, but the stones that exhaust the trees. Tie the shoots well in, so as to give the fruit the benefit of all the sun and air possible and insure its colouring, drawing aside the leaves that shade it. Take every precaution to have the foliage free from insects before syringing ceases, applying an insecticide if there is any trace of red spider, syringing forcibly afterwards.

Trees Started at the New Year.—Do not hurry the trees until the stoning is completed, making sure of that by trying a few fruits with a knife. Continue the temperature regular at 60° to 65° at night, and 70° to 75° by day until the stoning is completed; then, if the ripening is desired to be accelerated, it may be kept at 70° to 75° artificially, but falling 5° at night, and keeping through the day at 80° to 85° from sun heat. Close sufficiently early in the afternoon to run the temperature up to 90° or 95°, with plenty of atmospheric moisture, syringing early enough to have the foliage fairly dry before night, and admitting air early, so as to let the pent-up moisture escape before the sun acts powerfully on the leaves. Afford copious supplies of water to the roots, and liquid manure if necessary, with a light mulching of spent manure. Let the fruits have all the light possible, placing them with the apex to the light, drawing the leaves aside or shortening them. Thin finally directly the fruit has stoned. Secure the growths as they advance, keeping them thin. Pinch laterals at the first and every leaf, stopping growths for next year's bearing at about 14 inches, unless required for extension.

Houses Started Early in February.—With the fruits the size of Walnuts the thinning should be effected to a few more than will be required for the crop. Encourage no more shoots than are necessary for furnishing the trees with next year's bearing wood and extension growths. Pinch the shoots retained to attract the sap to the fruit at two or three joints, and to one afterwards as produced. Allow all plenty of light, for the solidity of the wood depends on the fibrous nature of the roots and the exposure of the growth to light. Ventilate early, commencing at 65°, and increase it with the sun heat, having it full at 70° to 75°. Maintain a temperature of 55° to 60° at night, and 60° to 65° by day artificially.

Trees Started in March.—When the Peaches are fairly swelling remove the superfluous fruits, beginning with those on the back or under side of the trellis, then proceed with the rest when it is seen which take the lead in swelling, removing those not wanted gradually. Follow up disbudding until the growths are removed to the number required, always reserving a shoot at the base of the current year's bearing wood, leaving those on extensions 15 to 18 inches apart, and allowing that distance between the extensions. Retain a shoot on a level with or above the fruit, and, if not wanted for extension, pinch out its point at the third leaf, and to every succeeding joint of growth. Train all other shoots in their full length as far as space permits, keeping them secured to the trellis, with ample space in the ties for the growths to swell. A temperature of 55° at night and 5° to 10° advance in the daytime is sufficient, ventilating freely above 65°. Syringe the trees twice a day in favourable weather, but only once when dull, and keep the borders well supplied with water, never letting the roots lack moisture.

Late Houses.—When Peach and Nectarine trees are in blossom the sight is pleasant, and the odour of nectar significant of a good set. Bees abound in the houses, and brush the flowers over with results alike beneficial to the grower and the apiarian. A little fire heat to maintain a day temperature of 50° to 55° insures advancement, admitting a little air top and bottom so as to promote a circulation. A chink at night is also beneficial, excluding frost by maintaining the temperature at 40° to 45°. Admit air freely at and above 55°, not allowing the temperature to exceed 65° without full ventilation. A genial condition of the atmosphere can be maintained by damping the borders and paths occasionally, but avoid making the atmosphere so humid that moisture condenses on the blossoms during the night.

Unheated Houses or Wall Cases.—The chief points in these structures are to secure a well ventilated atmosphere in the early part of the day, and to have the border well supplied with moisture, but not needlessly wetting the surface, which is best rather dry, especially towards evening, as it attracts moisture in that state, closing the house before the temperature is much reduced so as to enclose a moderate amount of sun heat. About 5 P.M. is usually sufficiently early to close the house for the day, as walls give out heat some time after closing, generally sufficient to insure the safety of the blossom if it is kept dry. Damping or watering should be done in the morning, so that superfluous water may be dissipated.

Vines.—*Early Houses.*—Grapes now colouring fast will require abundance of warm air by day and night, with plenty of atmospheric moisture, damping the paths, walls, mulching, or borders. This assists the Grapes in swelling, and preserves the foliage in health. A careful examination of the borders should be made, and if they are dry a liberal

application of tepid liquid manure will be a powerful aid to the Vines. Gradually reduce the night temperature as the Grapes ripen, keeping the atmosphere dry and cool; but guard against excessive dryness, as early Grapes with ventilation require much more water at the roots than late ones, with moderate air moisture for the benefit of the foliage, which must be kept clean and healthy as long as possible. When approaching ripeness moderate fire heat will be required to keep up a temperature of 60° at night and a little more in the daytime. Gradually remove fermenting material from outside borders, leaving a mulching of some that is partially decayed for the protection of the surface roots, and allow them to have the benefit of summer rains, which will wash the fertilising elements into the soil and stimulate the Vines into the production of new laterals after they are relieved of the crop, which tends to the health of the principal leaves.

Midseason Houses.—Attend to thinning the free-setting varieties as soon as the berries are set, but Muscats and other shy-setting kinds should be left until the properly fertilised berries take the lead. If a large percentage of the surplus bunches were not cut off before they flowered no time must be lost in getting them removed, and laterals that have been allowed to ramble may be stopped, tied, and regulated in accordance with the space at command. Inside borders may have a thorough supply of liquid manure or a top-dressing of fertiliser washed in, and a mulching of short rather lumpy manure. It is well to use sweetened horse droppings and spread them over the whole border in order to afford the Vines the benefit of the ammonia-charged atmosphere, adding a few fresh droppings from time to time; but care must be taken not to overdo it, or the ammonia will be too powerful for the tender foliage of the Vines. Where the Vines need extra support a liberal dressing of artificial manure may be given with great benefit, but it is necessary to follow the instructions carefully. Phosphatic, potassic, magnesian, and calcic elements are those chiefly required by Vines.

Late Houses—Bad breaks, as usual, are heard of where the wood has not been well ripened. In order to prevent its recurrence and the disposition to run to tendrils the late Vines should be started earlier, and ripened with more fire heat in late summer, so as to secure thoroughly finished fruit and perfectly matured wood. Various expedients are resorted to for correcting the evil, not any being better than stopping the shoots three or four joints beyond the fruit and tying the growths down to the trellis. Choose the latter part of a fine day for this operation, when they are limp, keeping them rather drier and warmer by day. Gros Colman and other late free varieties will now be setting; they will then have all the summer before them. These Grapes require a long time to grow and perfect; they also need abundant supplies of water and nourishment. Muscats and other shy-setting varieties should be carefully fertilised, operating on fine days when the temperature has reached its maximum, employing pollen from free-setting varieties, and maintaining a rather brisk, dry atmosphere. A temperature of 70° at night and 75° by day is not too much for Muscats when flowering. It is usual to leave surplus bunches until the flowering is over, which is a mistake, as Vines that do not set a proper number of bunches satisfactorily are not likely to do so better when more are left—indeed, it is better to make a selection of the bunches that are to remain for the crop before they come into flower, remembering that large and loose bunches are the worst for finishing, and the medium-sized and compact the best for ripening and keeping well.

Late Hamburgs—The Vines are moving rapidly, and need attention in disbudding, tying down, and regulating the growths. Do not stop the shoots until they are developed beyond the fruit to the extent of two joints where the space is limited, and four where there is room, pinching laterals below the bunch to one leaf. Above allow them to extend so as to insure an even spread of foliage over the space, but no more than can have full exposure to light, afterwards keeping closely pinched. Ventilate early and freely, so as to insure short-jointed sturdy wood and thick leathery foliage. Avoid overwatering the border, as a saturated condition of the soil is not favourable to root action, but keep it moist, especially any top-dressing or mulching, so as to encourage surface roots. If a few sweetened horse droppings are sprinkled on the border occasionally some ammonia will be given off, and other manurial matter will enter the border from them at each watering.

Newly-planted Vines.—When the roots take to the fresh soil the Vines will indicate it by growing freely. To secure sturdy growths ventilate early, and let all the growths remain that can have full exposure to light. Supernumeraries intended for next year's fruiting should have the laterals pinched at the first leaf, afterwards allowing them to make a few joints of growth, and pinching the cane at 8 to 9 feet length. Take every possible care of the leaves on the cane, not allowing them to be interfered with in any way by the laterals. Close early, with plenty of atmospheric moisture.

THE BEE-KEEPER.

SPRING FEEDING.

As a regular reader of the thoroughly practical remarks of "An English Bee-keeper," which appear from week to week in the *Journal of Horticulture*, I feel I should like to send a few notes on the important subject of spring feeding. I have been a bee-keeper for more than a quarter of a century, and will give the details of the system I have adopted during the major portion of that period.

At the present time and for some weeks to come bee-keepers will be occupied chiefly in feeding up their stocks, so as to have them as forward as possible when honey is abundant. The first fine day will see the bees carrying large quantities of pollen. This income after the long repose of the winter months causes considerable excitement as well as activity among them, and excitement from any cause is invariably followed by a rapid rise in the temperature of the hive. The natural result of this is a thorough warming of the cluster. The bees spread themselves out, giving the queen more freedom to move about on the combs; and she will, if this increased warmth is maintained for a day or two, commence ovipositing much more freely than before. On the other hand, if a day's busy pollen gathering is followed by cold weather, the excitement subsides, the bees cool down as it were, and cluster as closely as before. If the bee-keeper select the right day when the cluster is fully aroused, and supplement the pollen obtainable by a continuous supply of thin syrup, he has it in his power to keep up the abnormal warmth of the day's busy work, and the bees are stimulated or forced just as plants are by the action of the hot-bed. To make the matter quite clear, it must be understood that the bees' share of the work is simply to create and maintain a temperature sufficiently high to hatch the brood, while a good queen is always ready to hatch as many eggs as the bees can attend to.

When a start is decided on warm the food slightly. Do not give the first bottle till the evening, because a rapid supply of syrup given to half a dozen stocks on a warm day would be almost certain to induce a tendency to rob all round, and this should be very carefully guarded against. The following morning remove the bottle, whether all the food is taken or not, and substitute the slow feeder. Another thing must not be overlooked. Any weak stocks must be left unfed until the others have become accustomed to the feeding bottle. If a weak stock is fed at the same time as strong ones probably it will be attacked and the food taken from it as rapidly as given, in which case it is almost impossible to preserve it. The feeder should also be carefully guarded against bees reaching it from the outside.

About half a pint of syrup should be given as rapidly as the bees will take it on commencing to stimulate, after which I think the best guide as to quantity is 1 pint (or 1½ lb.), given at such a rate as will occupy seven days in taking the whole. Three and a half ounces per diem may not seem a great quantity to maintain a large colony of bees; but it must be remembered that by the time the stocks become strong there will be a natural income in addition, so that the amount suggested is abundant. If there is much sealed food in the hive a comb may have the cappings removed, and if placed in the centre of the bees they will at once take the honey to another part of the hive, leaving the cells ready for eggs.

When stimulating is successfully started the increased warmth of the coverings about the feeder becomes very perceptible. The bees constantly crowd round the source of supply, and are always on the look out for the food. The entrance of the hive must be contracted to about 1 inch, and every means be taken to add to the warmth of the coverings. There is no need for ventilation after February is passed, and crown boards may be used with advantage over the quilts.

An effective feeder may be made as follows.—Take a common pickle bottle holding about a pint, cut a square of very thin zinc (the thinner the better), make on this a circle the size of the bottle mouth, and with scissors cut the zinc so that the parts projecting beyond the circle may be bent down to the neck of the bottle, and tied on with a string. Three small holes punched in the zinc will give about the right quantity of food. If a thin board, the same size as the top of the hive, has a 1½ inch hole cut in its centre, is laid over the quilts, with a half brick or other weights on each corner to keep it down, a capital feeding stage is formed, and it only needs a small piece of glass for slipping over the hole when removing the bottle to make it complete.—OLD STAGER.

TO CORRESPONDENTS

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, London, S.W. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Postal Disarrangements.—In consequence of the Easter holidays more than usual delay seems to have occurred in the delivery of letters. At least such is our experience, both as regards letters we have posted and received. Postal officials, however, need a little relaxation, and this reference is not so much a complaint as an explanation why certain communications could not be attended to this week.

Tulipa Greigi and Narcissus Cynosure (A. B. G.).—The form of Tulipa Greigi that you send with the type is certainly beautiful, but such variations are not uncommon in seedling plants, and this yours may be. We have heard of several similar. The Narcissus Cynosure does not appear to promise anything valuable from a commercial point of view.

Chrysanthemum Seed from Japan (D. R. B.).—It is impossible to say what you may expect from the seed beyond Chrysanthemum plants. We hope, however, you will be more fortunate than Mr. Wells was with a packet direct from Japan. This gave him 2000 plants, but of these, if he is accurate, 1999 which flowered in 7-inch pots produced inferior single flowers, and were thrown away, only the remaining being "double," which he named Trafalgar. It was the survivor of a great slaughter certainly, but the Nelson of Earlswood lives to rejoice in honour of his victory.

Cytisus racemosus (Inigo).—The flower shoot forwarded by you was very much withered on arrival, but in all probability the above is the correct name. Certainly it is a Cytisus, of which you may readily increase your stock by the prompt insertion of cuttings of the shoots the plants are now so freely producing. Fill pots with light sandy soil, placing several cuttings round the sides. Keep these shaded for some days, being very careful in watering, and roots will soon be formed in any genial structure. Pot the young plants when such a course becomes necessary, and pinch out the points of the shoots so as to insure a dwarf, compact habit, for in this lies the chief beauty of the plant.

Peach Shoots Diseased (St. Leonards).—The leaves are affected by the silver-leaf disease, which is usually attributed to frost when it occurs outdoors, as it does very commonly on Plum tree leaves, also on Cherries, and frequently on Portugal Laurels. It is a puzzling malady, and in some cases fatal, often arising from poverty of soil. In your case, however, the tissues are crumpled of the mycelial hyphae of a fungus, which is, if we make no mistake, that of *Monilia fructigena*. The mycelium is perennial in the tissues, and the growth of this causes the gumming or sudden collapse of the shoots during growth, or even destruction of large branches. It is greatly influenced by nutrition, hence lifting is one of the best means of checking the tendency to its activity; indeed, that and cutting away the diseased growths and branches is the most effective remedy. Once in the trees, however, it is difficult to get rid of; the mycelium, though lying dormant, may wake up, and overcoming the resistive power of the tree cause gumming as bad as ever, hence many experienced cultivators consider removal the only perfect cure. We have, however, found lifting and a properly constructed border of sound materials, together with cutting out diseased parts very satisfactory, the trees growing out of the disease, as the saying is, but really eliminating it from their system. No external application is of any use in effecting a cure, though lightly dusting with a fungicide containing sulphate of copper in powdered preparation, such as fostite and anti-blight, may prevent the spreading of the parasite. Use substantial food, such as bone superphosphate 5 parts, muriate of potash 2 parts, sulphate of magnesia 1 part, and sulphate of iron half part, mixed, applying 2 to 4 ozs. per square yard. Lifting the trees at the proper time should be attended to, and cutting out and burning all diseased growths or wood. This will give the best results, at least such is our experience. This reply will equally meet the case of another correspondent.

An Empty Envelope from Dublin.—A duly stamped envelope addressed to Mr. J. Wright, 17, Fleet Street, has been properly delivered at 171; but it has never been gummed down, and if any letter were placed inside it, it has been lost in the post.

Prunus triloba (Erith).—If you refer to page 322 you will find that the name is not *Prunus triloba* but *P. triloba*, and it is correct, the leaves being three-lobed. The species was introduced from China in 1857.

Bouvardias (H. P.).—You will perhaps find the desired information in the article on page 342. If there are any particulars in which it does not quite meet your case, please specify them and the matter shall have further attention.

Sweet Peas Injurious to Tame Pigeons (W. S.).—Mice and rats are good judges of nutritive quality and value in Peas. They leave Sweet Peas severely alone, and they are not, as a rule, taken by wild pigeons. We have heard of similar occurrences to yours, but our pigeons refused the seeds. They certainly are not suitable food, and probably injurious.

Illustration (W. E. G.).—You were told that the illustration was not taken from the "Botanical Magazine," or any other work, but from a spray cut from a growing plant. If you had written when the illustration first appeared, and not years after, we could have sent you a specimen, but cannot do so now. We took some trouble to ascertain the facts of the case, and supplied you with the information as soon as it was available. We are obliged by the reference, but a visit to the libraries you mention is unnecessary.

Tomato Seedlings Withering (Anxious).—The plants appear very healthy at the roots and in the stems, nothing being amiss but a slight withering of the leaves. These were examined microscopically, without any trace of disease being found, outside or inside the tissues. The leaves appear to be scorched, due possibly to the tender growth flagging under powerful sun, especially after a few days of dull weather. This is a common occurrence, and can only be avoided by early and careful ventilation. The cold weather accompanied with the biting winds would conduce to the condition presented by the leaves. Grow the plants as sturdily as possible, not sparing attention in ventilating, especially in the early part of the day, for it is allowing the heat to advance considerably and moisture to settle on the leaves, then admitting air too freely at once, that cause scorching.

Clean and Dirty Flower Pots (B. Drayton).—Of course you are right. At no time can the great advantage of using perfectly clean flower pots be so well appreciated as when the plants are being turned out of them, as the roots and soil come out of clean pots as freely and smoothly as a jelly out of a mould; but if the pots were dirty inside when the plants were placed in them, the roots adhere to the sides, and half of them—and these are always the best—may be torn off during the process of removing the pot. Never, therefore, in potting use a dirty pot, but always have it washed clean inside, and dried before any soil is put in. This is just one of those little matters that have to be explained time after time before its import can be understood or is admitted. Even for years the matter has been made prominent, yet not a few persons either cannot or will not comprehend, and go on spoiling plants in hundreds. Practical lessons on the subject will soon be afforded during what is known as "bedding-out time."

Vine Leaf Rusted (E. S.).—There is no disease on the Vine leaf as caused by either insect or fungi, visible or microscopical animal or vegetable organism. The appearance closely resembles an attack by Vine-leaf mite (*Phytoptus vitis*) and even the Grape Vine louse (*Psylloxera vastatrix*), but there is one specific distinction—the leaf surface indentations are from the upper side downwards when caused by "rust" but in reverse order when induced by the insects. Both require harbour, and the plant structure grows away from them. The leaf is a very fine one, having plenty of substance, but unfortunately "rusted." This is occasioned by a sudden stoppage of the transpiratory functions, and may occur through the opposite extremes of a scorching and a chilling, commonly the latter, especially in your case, with which we have to deal at present. The cause is a chill. The atmosphere of the house has been allowed to become heated by the sun, and the moisture correspondingly expanded, which, with the sap made to flow freely upward by the heat, caused the stomata, or breathing pores of the leaf, to open, in the endeavour to rid the tissues of the excessive moisture; then the lights have been thrown open and evaporation greatly accelerated by the air drying. This is analogous to cooling, and the consequence is the tissues are chilled, the stomata close, and the mischief is done. In order to repair the damage the tissues form new cells, and this gives the thickened appearance to the leaves known as "rust," the dead cells being more or less intermingled with the living, and in consequence have a rusty appearance. This interferes more or less with the elaborating and assimilating functions of the foliage, but is not a material injury to vigorous Vines, as yours are. The avoidance of the evil lies in early and careful ventilation, a little air being afforded constantly, and care taken to enlarge the openings before the sun has raised the temperature to any great extent. This you will understand, and with it you have no occasion to feel alarmed. As the Vines are poor in roots you may accelerate their formation by the use of bone superphosphate, using about 4 ozs. per square yard, and pointing it in lightly, if it can be done without disturbing the roots, or you may use the following mixture:—Bone superphosphate 3 parts, double sulphate of potash and magnesia 2 parts, best air-slaked chalk lime and dry soot, in equal proportions by measure, 1 part, mix, and apply 4 ozs. per square yard, washing in moderately. It is often more convenient and equally effectual to Thomson's, Pearson's, Innes', or other advertised fertilisers, any or all being excellent for your purpose.

Ribes aureum (Nemo).—This is the name of the shrub of which you send a specimen. It is a hardy deciduous plant of great beauty that is well worthy of extended cultivation for affording that variety so desirable in mixed borders or shrubberies. Propagation may be effected either in the spring or autumn, selecting ripened shoots and inserting them in the open ground.

White Insects on Coleus Leaf (B. B. H.).—The snow-white insects belong to the order Hemiptera, sub-order Homoptera, tribe Aleyrodidae or "Snow Flies," which closely resemble small moths, both sexes having opaque wings of nearly equal length. The species is closely related to the Tomato white fly (*Aleyrodes vaporariorum*, *Westwood*), which also infests *Lantanas* and other plants in greenhouses, and has often proved injurious to Cucumbers. It is, however, larger than the Tomato fly, being one-eighth of an inch long, snow white, except in the thorax, which is brownish black, mottled with yellow and white. The yellowish body is covered with a lily-white shield, and beneath this innumerable eggs in a flocculent substance. This particular fly may be a form only of *A. vaporariorum*. This was first described and named by Prof. Westwood in 1856, and in 1886 it was very destructive to Tomatoes. The insects, by means of their beaks, abstract the juices of the plants, causing the leaves to become yellow, wither, and die. The eggs are deposited on the leaves; these hatch in about ten days into larvæ—white, oval, with two large dark patches on the back, and have six legs and two horns (antennæ). The larvæ feed on the juices of the leaf by means of a sucker, cover themselves with a white scale, turn to a pale pupa, and from this the insect emerges in about four days. It is rather difficult to kill this pest. Repeated fumigation with tobacco or vaporisation with nicotine essence have proved effective, and anti-blight powder has been found useful; but the most effectual means is to form flowers of sulphur into a cream with skim milk, and apply this lightly to the hot-water pipes whilst hot and the house closed. The fumes of the sulphur kill the flies. It must not be overdone, or it may prove injurious to the delicate-leaved plants.

Names of Fruits.—Notice.—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (F. F. G.).—1, Winter Pearmain; 2, Norfolk Beefing; 3, Newton Wonder; 4, Sturmer Pippin. (G. H. F.).—1, Fine specimens of Bramley's Seedling; 2, Wellington; 3, Round Winter Nonesuch; 4, Easter Beurré. (F. E. C.).—1, Nec Plus Meuris; 2, unknown, worthless; 3, Nouvelle Fulvie; 4, Olivier des Serres; 5, Passe Crassane; 6, Brownlee's Russet.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, at being often difficult to separate them when the paper is damp. (J. P. P.).—Your specimen was considerably withered, but it is possibly *Læliopsis domingensis*. (T. C.).—1, *Selaginella Kraussiana*; 2, *Cystopteris fragilis*; 3, *Pteris umbrosa*. (J. H.).—1, *Dendrobium Wardianum*; 2, *Vanda suavis*; 3, *Odontoglossum crispum*, poor form. (A. W.).—1, *Cypripedium hirsutissimum*; 2, *Dendrobium fimbriatum oculatum*; 3, *Adiantum grandiceps*; 4, *Asplenium bulbiferum*; 5, *Adiantum capillus-Veneris*; 6, *Pteris cretica*. (G. E. B.).—The leaf arrived dried and crushed like brown paper. The tuber is an *Achimenes*. Pot in loam and peat, and grow in a warm house. (J. B. C.).—1, *Thuia orientalis*; 2, *Forsythia viridissima*; 3, *Ribes aureum*; 4, not recognisable; 5, *Lonicera hirsuta*; 6, *Phillyrea media*, var.

OUR POULTRY YARD.

THOSE who are the personal attendants on live stock ought, and do, know most of the requirements and management of the living creatures committed to their care.

We as outsiders leave as a rule the poultry yards to our wives, and we have persuaded a lady of our acquaintance, who is a successful poultry rearer, to give us her experience. She obliges as follows:—

To begin with, I should just like to say that I am a tenant-farmer's wife, with no money to waste on fads and fancies, and that I am bound to make the most of my fowls, as on them I depend for many household things as well as the clothing of myself and children.

There are no costly appliances in the way of coops, chicken houses and the like, and I cannot afford to give £2 2s. for a pure-bred cock. It would not pay me to go in for special breeds—there might be a difficulty in keeping them pure if the eggs were sold guaranteed for breeding purposes, and so far there is to my knowledge no particular breed which will combine egg-laying qualities, early sitters, and good table birds.

Some of the recommended sorts are too delicate for a northern climate. Houdans, which lay well, suffer much from frosts; indeed, they lose toes, and get into a very low, weak state, while Leghorns lay well, will not sit, and present a wretched appearance on the dish. Orpingtons I could not get to live. Perhaps it was my want of management. My strain is now a mixture of Houdan and Langshan, Indian Game and Dorking. I have two or three Cochins, as I find they come to maturity early.

By keeping a few old birds in the autumn, when the hen selling is going on, I provide myself with fairly early sitters. It does not pay to grow fowls for market; at least, not as I grow

them. Of course, if the fattening department were adopted things might be different. Then a proper building would be necessary, and I should need help beyond what I can supply myself, and the wages of a boy and the extra food preparation would make a great hole into my profits. The idea I have carried out is to produce plenty of eggs with a minimum of labour, fowls to keep up my breeding hens, and a few couples for the table. Of course, one's best laid plans go amiss sometimes, and it is awfully aggravating to see a preponderance of young cockerels in the yard in place of their sisters. However, by sending these alive to market there is no need to take a bad price; they can always be brought home, and wait for the next week.

Unless an incubator is very good, and consequently expensive, you are better without it, and to speak truly, I have no capital wherewith to buy such a thing, nor place to keep it in when bought. Now as to sitting hens. On the first symptoms, a nice nest is prepared on the ground in an old dog kennel, disused rabbit hatches, or under a coop. The nest is made of a grass sod, grass side downwards, the earthy part hollowed out and lined with a bit of hay.

Madam is inducted into her new home at dusk, and suitable food and water is placed within reach. When coops are used chicken feeders are put in front so as to allow the hen a bit of exercise ground, and I take care she shall have a plentiful supply of dust and lime. I have no time to let hens out exercising every day—they must do their own exercising. I like to vary the food of a sitting hen a little, and often introduce a piece of Mangold or a Swede Turnip to their notice. If the weather be warm the eggs should occasionally be sprinkled with tepid water; indeed, towards the end of the three weeks ours are usually washed.

A little help is often needed when the egg is "sretched." Sometimes a chick is too weak to get itself fairly out of the shell. Then, too, an egg may be very much crushed—care and a little warm water will work wonders. The chicks come into a warm basket by the fire as soon as they are hatched, and when all are off and on their legs the mother is put down at once on the bare ground. Should the weather be very bitter a little chopped straw will make things more comfortable, or peat moss litter and an old sack put in front. For the first day the chicks require little or no food. Then they get chopped-up eggs, bread steeped in milk, and small rice. Before each coop is a chicken-feeder—a three-sided frame of rough wood with a wire top.

For the first few days I let the hen feed with the chickens for two reasons—she teaches them how to eat and gets a bit of good fresh food herself, as after three weeks of close sitting she is much out of condition. After that time the chicks are fed separately in the feeder, and coarse grain is given to the hen in the coop. On no account should a coop have a bottom—it is simply impossible to keep them clean, and I move my hens daily. I am certain this is a great point. Nothing can thrive among smells, and a coop with a hen and ten or a dozen chickens soon gets very nasty. I have never had a swill tub all my life, but instead keep in the kitchen a small tin can in which are put all the morsels from the plates. In a large household there are always bits. People will not eat up bread crusts, and bread puddings are so *nauseous*. The trimmings of toast, bits of potato, pudding, vegetables, sauces—all these I turn into chicken food, and I also appropriate all the old milk I can get.

In winter a large basket hangs from a bacon hook in the kitchen, and receives many contributions in the form of crusts; being in so warm a place there is no chance of mould, and warm water or milk will soon reduce the hardest crust.

Of course a mistress must have the co-operation of her cook, but this is a thing I have never found difficult. We have some thick hedges here, and our hens are accustomed to lay among the roots. This I always encourage, and I get some of my best "clutches" out of the Yew hedge in the garden. Occasionally I am unkind enough to substitute the egg of the duck, but the patient does not grumble.

One great point in rearing healthy chickens is to change the feeding and rearing ground every year. Of course this is not always possible, but even if the distance from the house is greater the henwife will find repayment for her extra trouble in a clean bill of mortality.

The coops and the feeders can be easily knocked up by a handy groom, and nothing makes a better refuge for the bigger chickens

than a huge heap of thorns—it acts both as a shelter from wet and sun. It is desirable to set two hens the same day, so that if by any mischance the broods are small the chicks can be amalgamated, and only one coop needed. Never let young chicks out in the very early morning, that is if there has been a white frost or heavy dew.

I only rear a few ducks for the table; these are penned up on grass in a shady situation. Young ducks, if they have the least chance, are dreadful gadabouts, and trail off, heedless of distance or damp grass. Young ones cannot stand this. Their food is meal mixed stiffly, and ducklings must have a good supply of water. An old panchen sunk in the ground and filled with stones, to act as refuges, makes a capital watering place.

I have a great belief in broken pottery or flint for fowls. Their teeth are in the stomach, and they need sharp grit of some sort to aid mastication. Natural grit often fails, and therefore if much poultry be kept it is absolutely essential to provide substitutes. All our broken crockery ware is put aside, and when there is a spare half hour is converted into chips by the aid of a flat iron on a defunct iron boiler. Then scattered in the yard it is most amusing to watch with what avidity the sharp morsels are swallowed. I may not say more. As to sale of eggs the local market is "too too," so my eggs are consigned to a dealer in a large manufacturing town, and when I have paid his commission and railway carriage I am still largely into pocket over our market price.

WORK ON THE HOME FARM.

We have finished drilling spring corn, and that sown early is well above ground. The weather, however, is so frosty that much damage may be done to the young blade. We hear of 12° of frost being registered, and ice half an inch thick. The forward Wheats are showing a yellow tinge in the lower parts of the fields, the natural effect of such weather late in April. We have had a little rain, but the temperature does not rise.

Pastures have now become very bare, indeed, and store stock have had a serious drop in price. We trust it will only be a temporary one, and that warmer weather and growing grass will soon put more confidence into the mind of the grazier.

We are top-dressing our Wheat—at least, that which was sown after Potatoes. Ninety pounds nitrate of soda, 2 cwt. superphosphate, and a little common salt per acre make a good mixture; but the mixing should be done carefully, as the ingredients vary so very widely in character and strength.

One field of Wheat we are sowing with small seeds for one year's pasture. We are sowing the manure mixture first, then the seeds, and harrowing all in together. The Wheat is a strong good plant, and will be all the better for a little knocking about and earthing-up; it is, indeed, difficult to harrow Wheat too much.

This field is an example of what can be done to a very foul piece of land by a course in which are two successive green crops. It is a very light sandy field, and two years ago was exceedingly full of Twitch (this was chiefly owing to a very wet bad following summer for the previous Turnip crop). In 1895 Turnips were sown; there was a fair crop, and they were consumed on the land. Last year a Potato crop was taken, and now a man would make a very poor wage if given 1s. each for every plant of Twitch he could find amongst the growing Wheat; at any rate, we have searched, and failed to find one so far. This course of cropping can be commended with confidence to the attention of those who are farming land of this description.

11th.—Sunny most of the day; cloudy evening.

12th.—Overcast all day, with occasional spots of rain in morning.

13th.—Much bright sunshine, but overcast at times.

14th.—Gale and rain in small hours and wet till 9.30 A.M.; gleams of sun from 10.30 A.M., and bright afternoon.

15th.—Brilliant early; alternate cloud and sun during the day, with occasional sprinkles of rain.

16th.—Sunny early; overcast day, with drizzle and showers at intervals.

17th.—Steady rain in the small hours and overcast and showery day, with occasional gleams of sun.

A week of typical April weather. Temperature as a whole very near the average, but considerable range, and a sharp frost on the morning of the 11th.—G. J. SYMONS.

NEW FUCHSIAS.
1897.

Mr. WILLIAM BULL

Is now sending out the following splendid **NEW FUCHSIAS.** They are all superb varieties, and can be confidently recommended.

BALTIC, short bright crimson tube and sepals, the latter well reflexed; rich purple single corolla, veined at base with crimson.

LATONA, short tube and recurved sepals of a coral crimson colour; full double white corolla shaded at base with deep rose.

LUCIUS, very large and broad bright crimson sepals, completely reflexed, tube short; large white corolla, veined with rose at the base.

OBERON, a charming light Fuchsia with white tube and sepals, the latter semi-reflexed; single corolla, bright rosy carmine shaded magenta.

OVID, short coral-red tube and sepals, the latter broad and well reflexed; immense double white corolla, shaded magenta, crimson at base.

TRIBUTE, very short tube and completely reflexed bright reddish crimson sepals; violet-purple single corolla, veined and shaded at base with crimson-red.

NEW DROOPING FUCHSIA.

PENDANT, a very remarkable variety of strikingly weeping or pendent growth, admirably fitting it for growing in baskets, &c. The flowers, which are abundantly produced in clusters, have short tubes with long and broad extended carmine-pink sepals; corolla, single or semi-double, rich plum colour, shaded with deep rose at the base.

Price 5/- each, or the Set of Seven for 30/-.

NEW FUCHSIAS,
1896.

Sent out by **Mr. WILLIAM BULL.**

BELLONA, short tube and completely reflexed sepals of a rosy-carmine colour; large white double corolla, suffused and veined rose-pink.

CALLIOPE, large double flower; corolla, rich violet-purple, short tube and broad crimson sepals.

CERES, very short crimson tube and sepals, well reflexed, very full spreading double corolla, pale blush thickly marbled and veined with deep pink. Very distinct.

DORIS, short tube and large broad coral-red sepals horizontally extended; immense double corolla, petals reddish-purple, margins shaded with metallic blue.

FORTUNA, short tube and broad reflexed crimson-red sepals; large semi-double white corolla, heavily shaded rose and marked crimson at the base.

IRENE, short red tube and sepals; well reflexed, single reddish-violet corolla marked with crimson at base and well extended.

IRIS, short tube and broad carmine-crimson sepals, large double white corolla, shaded with rose and flaked rose-pink.

LEDA, short tube and very broad reddish-crimson sepals, irregularly reflexed; corolla bluish-violet veined with crimson and much expanded.

METIS, short dark rose tube and sepals, the latter well reflexed; double white corolla marked deep rose at base.

ROSALIE, short bright crimson tube and sepals, horizontally extended; large double white corolla, veined at the base with cerise-pink.

SERENA, very short rosy-pink tube, sepals completely reflexed; immense double spreading corolla, blush rose veined with deep pink.

THALIA, short tube and broad coral-crimson sepals, well reflexed; semi-double white corolla, the petals well expanded, suffused with rose and veined crimson at the base.

Price 2/6 each. The Collection of Twelve for 24/-

SETTING GRAPES.

ONCE more the season is approaching when the bulk of Grapes grown under glass will be in flower. It is an anxious time for the cultivator, for a bad set not only means a partial loss of crop, but also bunches which will be an "eyesore" instead of the "pride" of their grower. With healthy Vines well managed a good set with the majority of varieties may generally be insured, but a few sorts are proverbially inconsistent, as the same cultivator will often have the greatest difficulty with them in one district, while in another, though carrying out the same cultural details, the results will be singularly satisfactory.

There is, of course, always a reason why this is so, but it is not an easy matter to find it out. When the Vines are unhealthy, old, or the root action sluggish, a sufficient cause for failure may at once be advanced, but when the Vines are right on each of these points, and the houses kept at the recognised temperatures, the matter becomes somewhat puzzling. Some famous Grape growers have, after much study and close observation, found out that failures of this description are occasionally caused by a deficiency of lime in the compost forming the borders. All who have difficulties such as those above indicated still unsolved would therefore do well to give their Vine borders a dressing of lime, to be followed by a thorough watering, before the bunches are in flower. This is all that can be done in that direction at present, but the point should be borne in mind, and a dressing of lime given to the border next autumn.

In all instances borders should be examined just before the flowering period to ascertain if water is really required; if the soil be slightly dry a foot from the surface a copious watering ought to be given, but I do not like the practice of watering as a matter of course without previously testing the state of the border, for should this be in a sodden condition an additional deluge of water is quite sufficient to ruin the prospect of securing a good set. Over-anxiety is, I fear, often the real cause of the failure of many crops. The cultivator is so anxious to do all in his power to attain startling results that enthusiasm over-balances sound judgment, with disastrous results.

Let us now suppose that the errors above pointed out have been avoided, and that we have to deal with healthy Vines with plenty of bunches, little difficulty should then be experienced in securing a good set.

I have at various times tested every method I have heard or read of for securing a good set of Muscats. In bright weather a perfect set may be obtained by lightly syringing the bunches at noon. Drawing the hand over the bunches is also a good plan, and by the use of the rabbit's tail results in every way satisfactory have been obtained; but I am convinced that neither of these practices is necessary, as shaking the rods several times daily, and at noon tapping each lateral carrying a bunch with a stick is equally effective. The only exception is in the case of very large bunches. On the points and shoulders of these I like to pass the rabbit's tail or hand, as the pollen seems to drop away from these places when the Vines are shaken.

There is nothing like plenty of fire heat for Muscats in flower. The night temperature should range from 65° to 75°, and from 75° to 80° by fire heat on dull days, in bright weather keeping the fire in check but never allowing the hot-water pipes to become cold. Air should be given in greater or less quantity throughout the day, the object being to maintain a free and regular circulation rather than a sudden inrush of air whenever the sun happens to burst out between the clouds. It is surprising how little it is really necessary to open and close ventilators even in changeable weather, provided a small amount of air is admitted just before the sun strikes the house. On cold nights the house should be closed, but during warm ones the time-honoured "chink of air" may with advantage be left on. Many Grape growers seem to entertain the opinion that the atmosphere of a house in which the Vines are in flower cannot easily be kept too dry. This, however, is a mistaken idea which is gradually disappearing. Where the old order of things remains it is a fruitful source of bad attacks of red spider and an aid to the production of imperfectly fertilised berries, instead of having as intended an opposite effect.

It must, I think, be apparent to anyone who has watched a house of Muscats in flower that the tender foliage cannot endure with impunity very high temperatures, without a certain amount of atmospheric moisture is also kept up. If this is not done the energies of the Vines are crippled, the leaves become flabby, and therefore unable to perform their functions at a critical time. Under such conditions how is it possible to obtain a satisfactory set? If we consider thoroughly the reason why a comparatively dry atmosphere is maintained at flowering time, it will not be difficult to so arrange our treatment as to secure the object in view without injury to the Vines. We want the pollen of the bunches in flower to be thoroughly dry by noon, so that when shaken it disperses in the form of dust, and settles upon the stigma of each flower. When this has been accomplished dry atmospheric conditions are not necessary for the next fifteen hours.

In practice the plan I find answers perfectly is to sprinkle the house freely at 9 A.M., after the Vines have been shaken; at noon tap each lateral with a stick, and early in the afternoon, when ventilation is reduced, damp the floor of the house thoroughly, and syringe the walls should the weather be bright. A moderate damping is again given in the evening. Other varieties of Grapes which do not need such high temperatures only require, of course, a proportionately less amount of damping.

The night temperature for these should range between 62° and 65°, with a rise of 5° during the day. Alnwick Seedling from its peculiar construction requires an extra amount of attention at the flowering period, as the tiny caps which cover the flowers are not generally thrown off naturally, as in the case of other varieties. The pollen is also scarce. A good set may, however, be secured if the rabbit's tail is passed over other varieties in flower till it has become charged with pollen, and then drawn over every part of the bunches of Alnwick Seedling. Foster's Seedling is often considered a bad setter, and at one time I used to draw the hand

lightly over each bunch, I am now content with tapping the laterals, which results in a perfect set.

In the case of large bunches of Gros Guillaume, Trebbiano, Black Hamburgh, and Buckland Sweetwater, I use the hand or rabbit's tail, as there is a danger that some berries at prominent points do not get properly fertilised. Gros Colman, Madresfield Court, and Gros Maroc are as a rule good setters, and are quite satisfactory when given the occasional shake. Lady Downe's is, according to my experience, somewhat uncertain; but passing the hand over the bunches is the best aid to fertilisation I have yet tried. Before concluding let me repeat that unhealthy Vines and deficient root action are, I believe, in nine cases out of ten, the principal cause of the failure to secure a good set of Grapes. Those, therefore, who experience difficulty in this respect must first establish their Vines in perfect health before they can hope for greatly improved results. The science of Grape growing is simple indeed if cultivators would not play "fast and loose" with the principles which underlie successful fruit culture generally.—POMONA.

TREATMENT OF SEEDLING PLANTS.

AFTER seeds of half-hardy and tender annuals, greenhouse perennials and others that may be sown in spring, have successfully germinated, the seedlings under favourable conditions of growth soon advance in size. Provided each little plant has sufficient room for its first seed leaves and the development in their early stages of the rough leaves which immediately follow, there is little cause to fear injury to the seedlings. But where seedlings, whether from avoidable or unavoidable causes, have grown too thickly together, the first opportunity must be taken to afford the proper amount of space which is so desirable and essential to the satisfactory progress of all seedlings.

If crowded the young tender stems lengthen in their endeavour to carry the leaves where plenty of light can be obtained. In doing so they naturally become weakened, and the whole plant is then more likely to succumb to any adverse influences. The moral then with seeds is to sow them as far as possible thinly. If sown more thickly than desirable, and the seedlings when germinated are crowded together, the greatest possible care should be afforded not to keep them in a temperature higher than necessary. At the same time give them every assistance in supplying unobstructed light in a position near the glass, whether that is a frame, greenhouse, or stove.

In regulating the amount of light powerful sunshine must be taken into consideration, affording shade from its drying or burning influence in the case of any seedlings to which an excess would be injurious. The seedlings might receive direct injury, or the soil in which they are growing rapidly lose its moisture by evaporation. Rational treatment in the early stages prevents injury and assists the little plants to assume a sturdiness which is helpful in re-establishing them in boxes, pans, pots, or frames. Moreover, the work of pricking out or transplanting can be done earlier and with smaller examples than when drawn or spoiled by crowding.

The preceding remarks apply to plants the majority of which are raised from seed every season in spring, and are grown afterwards for various purposes indoors and out. For the greenhouse, Begonias, Gloxinias, Streptocarpus, Fuchsias, Cyclamens, Primulas, Cinerarias, Petunias, and Coleuses are included. For the flower garden, Stocks, Asters, Marigolds, annual Chrysanthemums, Zinnias, Dahlias, Scabious, Carnations, Helichrysums, Pansies and Violas. In the case of vegetables, special treatment of young plants or seedlings is only needed in frames with Celery, early Cauliflowers, Brussels Sprouts, Lettuce and Tomatoes.

It frequently happens that much benefit is derived from pricking out or transplanting, other than that received from increased light, air and space. The roots like to ramify in fresh soil, and the stems of some plants, for instance Tomatoes, may be sunk deeper in the soil than formerly with advantage. Additional roots issue from the buried stems. This serves to strengthen and to dwarf the plants. It may be adopted with most fibrous-rooted plants, but not with seedling bulbous or tuberous-rooted plants like Cyclamens, Begonias, and Gloxinias.

The seeds of Begonias, Gloxinias, and Primulas frequently germinate irregularly, and it follows that the seedlings cannot all be transplanted at once. Choose the most forward as they become large enough for the purpose. This can usually be done, with a little care, in lifting out those that are ready with a small notched stick or raising gently with a flat-pointed label. Leave the smaller

undisturbed. The last to germinate are usually the choicest varieties, of which care ought to be taken.

The compost suitable for pricking out choice and tender perennials should be light, open, and sandy; sweet leaf soil and fibrous loam in equal parts, with a liberal addition of silver sand, is a mixture in which almost anything in a young state can freely make roots. A medium, regular condition of moisture must be kept. This is readily attainable in a suitably moist atmosphere such as a vinery or intermediate stove temperature at this season. The practice of lightly syringing the small plants and soil may be daily resorted to for affording the necessary moisture without unduly saturating the soil. The limited supply of roots which the seedling plants have at first are easily catered for, provided the atmosphere is not too dry, and the soil when placed in the receptacles was moist throughout.

The soil should be placed in firmly, though not pressed hard. Provide efficient drainage, so that the more copious supplies of water required when the plants become larger may readily drain away. A fair amount of subdued light in a position somewhat removed from near the glass may probably render direct shading from sunshine superfluous. Should the shading, however, be required it must not be neglected, either in placing it on or taking it off. Harm may be done in both ways, and the careful grower will hit the happy medium as each day requires it. It is best to dispense with as much shade as possible compatible with the health and progress of the plants.

The majority of half-hardy plants are considerably benefited in habit, sturdiness, and rooting power by judicious transplanting from the seedling pots and boxes. As a matter of fact, it is impossible to grow many of these without this desirable assistance. Boxes, pans, and frames may be employed according to the requirements or convenience. For accommodating boxes or pans a frame or cool house is necessary to afford a start. Low lean-to frames partly filled with manure and surfaced with several inches of good soil will accommodate hundreds of Asters, Stocks, Marigolds, Zinnias, annual Chrysanthemums, Tagetes, Phlox Drummondii, Helichrysums, Larkspurs, Indian Pinks, Pansies, and Violas. Prick them out about 3 inches apart. Old potting soil made moist and placed firmly on the manure is the most suitable material.

Boxes and pans may be lightly drained with a few crocks, and over them a layer of flaky manure or leaf soil. Fill up with compost pressed down and made smooth on the surface. They are then ready for the plants, which may be inserted with a wooden dibber, giving them space according to the habit they are known to assume, placing them in lines across the boxes. If the compost is used moist, as it should be, heavy watering at first is not necessary. The plants and soil can be maintained healthfully moist by syringing, also by keeping the frame or house rather closer for several days, and if really necessary give a light shading during the hottest sunshine to any young plants that do not appreciate excessive light.

When fairly well established discard shading and afford air in gradually increasing abundance. Finally remove the lights from the frames or place the receptacles outdoors to thoroughly harden the plants before planting out. The period after which half-hardy bedding plants are safe for full exposure is the 24th of May in the northern counties, and a few days earlier in the southern. There are sheltered positions, however, where May frosts do not reach, such as in the vicinity of shrubs or buildings. These may be utilised for temporary protection. In the absence of natural shelter or the scarcity of frames or light canvas coverings supported on framework are necessary to harden the plants in boxes or pans. Beds for pricking out seedlings may be formed and temporarily protected until the plants are safely established.

Earlier in the season Lettuce plants raised thinly in boxes are finally pricked out in beds of good soil, affording the protection of a frame. Due supplies of air must be given on all favourable occasions to promote sturdy growth, dispensing with protection as soon as possible.

The early and main crop Celery plants are usually obtained by growing them in boxes or frames in generous soil, placed on a slightly warm bed of manure; but this is not absolutely essential, though it is desirable that the young plants should root into a few inches of decayed manure under the soil. The manure may be placed on a hard bottom, which will promote fibrous rooting, and the plants when ready easily lift, with material adhering to the roots. In the absence of convenient frames place the seedlings in moderately deep boxes, employing a layer of decayed manure one-third the depth, filling the rest of the space with good soil. It is needless to say that Celery plants prepared on these lines are superior in every way to those left without special treatment in the early stages.

Tomatoes, as above indicated, are greatly improved in sturdiness by a few transplantings or repottings, sinking the stems lower each

time. Roots issue freely from the buried portions of stems, and benefit the plants considerably.

Brussels Sprouts, Cauliflowers, Cabbages, Savoy and other Brassicæ require to be strengthened by pricking out the seedlings when the first rough leaves are being formed. As a rule none of these, except those intended for exceptionally early supplies, requires the aid of glass. Good fertile soil and an open sheltered situation should be selected. Place the seedlings 4 inches apart, with the roots straight down. Give water occasionally and keep free from weeds, which will be all the attention needed until large enough to plant finally.—E. D. S.

ASPARAGUS CULTURE.

INSTANCES are known where Asparagus beds have given satisfactory results for fifty years. Certainly thirty years is not too long to expect them to flourish under suitable conditions. Almost any kind of soil may be made to grow Asparagus by suitable preparation; but a deep friable loam, with a porous subsoil, is usually preferred.

Where the soil is naturally wet, or even heavy, and consequently retentive of moisture, it ought to be trenched a yard deep, and raised 9 inches above the natural level to insure the roots against premature decay. Asparagus cannot be successfully grown in a situation that is in any way shaded. An open position, away from high walls or overhanging trees, is preferred, as all the sun possible is necessary to insure success. Asparagus is usually planted in beds 4 feet wide; this size admits three rows of plants, one in the centre, and the two outer rows 10 inches from the edge.

As trenching proceeds the surface soil should be retained in the same position. If the soil 1 foot below is heavy in character it is advisable to remove the worst of it, using an equal bulk of roadside refuse and decayed vegetable matter, thoroughly mixing this with the surface soil. The beds ought to be prepared fully two months before planting to allow the soil to settle down to near its natural level. One month before planting fork in 9 inches below the surface a liberal dressing of farmyard manure. If more beds than one are to be made alleys 2 feet wide should be allowed between them. This space can be profitably employed during the spring and early summer in the growth of Cauliflowers or Lettuce, the rich nature of the soil being just suited to these quick growing vegetables.

If Asparagus is required quickly two-year-old plants should be employed, but where time is not so much an object plants raised from seeds sown the second or third week in April give satisfactory results. The early part of April is a good time for planting. Everything should be in readiness when the crowns are received from the nursery, the surface of the bed raked fine, and the rows marked out, as exposure of the thick, fleshy roots to drying winds is most injurious. Choose a dry day for planting, mark out the rows, then with a spade throw out the soil 3 inches deep, and sufficiently wide that the roots can be spread evenly, keeping the crown of the plant in the middle of the row. Cover the roots with some friable compost such as road grit and decayed vegetable matter, or old potting soil to which sand has been freely added. Return the soil to the row over the special compost, and rake the beds level. A distance of 15 inches should be allowed between the plants in the rows.

In the event of the weather being both hot and dry during May mulch the surface of the beds with 2 inches of half-decayed horse manure. Nothing is better than the materials from a spent Mushroom bed for conserving the moisture in the soil—the object of mulching. Should the weather be exceptionally hot and dry during June and July a thorough soaking of the soil will do much towards aiding the growth, which is especially important the first year. The beds must be kept free from weeds. Cutting should not begin until the second season, but little then. Asparagus receives a serious check to growth and maturity if, as sometimes is the case, the “grass” is much blown about, and consequently the crown of the root injured. Each strong stem is worthy of a stake, or short Pea sticks thrust in the ground at intervals will afford the plants useful support.

Early in November the stems ought to be thoroughly ripe, and should then be cut down to within a couple of inches of the soil. With a fork lightly break the surface, and cover with 3 inches of half-decayed stable manure. Some persons dig out the soil from the alleys, using it to cover the manure. This, in my opinion, is not a good plan, as many of the roots are injured in the alleys. The manure affords ample protection against frost without the addition of soil.

The first week in April rake the bulk of the manure into the alleys, where it will decay and provide a capital rooting medium for the Cauliflower and Lettuce alluded to earlier. A sprinkling

of common salt over the beds when raked down in the spring will prevent weeds and otherwise act beneficially. Liquid manure is a good stimulant for Asparagus when in full growth. It is on growth made during July on which the next year's crop of heads so much depends. Too many persons continue cutting Asparagus longer than is good for the plants. The middle of June is the time to cease. Connover's Colossal and Sutton's Perfection are two of the best varieties with which I am acquainted.—E. MOLYNEUX

HARDY FLOWER NOTES.

VIRGIL'S Tityrus, reclining peacefully under the canopy of the spreading Beech, is sometimes taken as typical of rural felicity. Happy and prosperous, he was the envy of less fortunate swains whose lot it had not been to enjoy the favour of so powerful a patron. The writer is in less happy mood. He is reclining too, but under his own roof-tree, and between the sheets, and so cut off from the opening of the flowers, and the glad sights and sounds of the garden in April. Relapse after relapse of influenza culminated in an attack which acted so injuriously upon a slight injury to one of the lower limbs, that he has no prospect of moving about for some days at least. Thus the present notes cannot fail to lack the freshness they might have had if inspired by the pleasures of the garden itself. By dint of craning one's neck or by supporting oneself with a chair for a second or two in course of a limping progress to and from the fireside while the bed-making is in course, we can catch a glimpse of the garden now displaying its spring treasures.

It is only a glimpse, and if, like Oliver Twist, we ask for more, it is only in part given by some cut flowers brought in, or by a verbal report from the *cara sposa*. All this is sheer egotism, however, and is only excusable on account of our desire to apologise for what must be the dulness of the succeeding lines. Though cut off from the garden for the time, we know well what flowers are to be seen now. The Trumpet Daffodils have not yet passed away to their summer's rest, and still droop their heads gracefully or stand boldly to invite the gaze of the passer-by. The short-cupped varieties are now in profusion to bear them company, and to help to cheer and charm us. We study their beauty joyfully, yet wistfully, as we look at the cut flowers before us. Joyfully because of their exceeding loveliness. Wistfully because we cannot see them as we love them best, with heaven's canopy overhead, and the soft breezes of April dallying gently with their flowers and leaves.

We hear glowing accounts of the beauty of such as C. J. Backhouse, Sensation, Duchess of Westminster, Princess Mary, William Backhouse, and others, but as we know them we deny ourselves the pleasure of having them brought into the house, preferring rather to let them seed in hope that we may be able to add one or two flowers to the improvements all who love the Daffodil look for in its blooms. The weather has improved, and April now woos them less roughly. Not with gentle words and soft movements, but with hailstorms, drenching rains, and wild winds did the month at first court the Daffodils. Enpress and some others of similar habit maintained their dignity, but the white Trumpets, such as cernuus, Colleen Bawn, albicans, Mrs. J. B. M. Camm, with other modest flowers, bore the rough treatment with gentle forbearance, looking down to the sodden ground as if appealing for more gentle treatment. Fortunately, every day was not the same, and when the sun shone for a few hours all was changed.

The honey bees from their hives, the humble ones from their holes in the hedgerow bank, came into the garden and buzzed noisily among the flowers, bearing them down by their weight. Even the tortoiseshell butterfly, tempted by the bright sun to essay flight, fluttered from flower to flower. What was there to bring these welcome marauders to the garden's bounds, inducing them to leave the wider pastures beyond? Shall we tell? We have told of the Daffodils, but they form not a tithe of the garden's bloom.

Great clumps of Arabis, which we should call "like snow" were it not for the yellow seminal organs, abound, and to these the winged creatures which add so much to the garden's pleasures hie their way. It is a "common" flower, and so by many thought not worth growing. Common though it is, this Rock Cress is not often seen at its best, forming compact mounds of flowers among which not a leaf is to be seen. Here on the dryish soil and generally on a slightly raised position it is perfect in its season.

So, too, it may be said of the Aubrietias. I sometimes think that he who can bring such flowers as these into greater notice confers upon his countrymen and countrywomen a true boon, giving them a new interest in this work-a-day world, a fresh zest in life, and often a key which will open the way to a store of hidden treasures. The brightest of our Aubrietias are bright indeed, and make the old *A. deltoidea* look dull and dowdy beside

them. I know a little front garden in the outskirts of a neighbouring town where some beds are edged with this old species, and every time I pass it I feel a strong inclination to advise the owner to replace it with some of the brighter kinds, such as Hendersoni, Eyrei, or Leichtlini, which come fairly true from seed. I am more tolerant of a few of the pale varieties in my own garden, but I have many of the newer plants in all positions. At present they are bright masses of colour, delightful in every way, and especially on rockwork, giving little or no trouble beyond a clipping over with the scissors after flowering.

Charming little flowers are some of the Muscaris, or Grape Hyacinths. The common *M. botryoides* can hold its own with almost any of them for beauty of colour, but with our usual perversity and craving for "something new" we seek to add others to our gardens. Some of these are inferior, but others have points of beauty which make them acquisitions. Of the latter class is *M. conicum*, which I was pleased to see recently received an award of merit from the R.H.S. when exhibited by Messrs. Barr & Son. Very fine in its way is this bright blue Grape Hyacinth, which I have grown for several years. Another Muscaris appears to have been shown lately as *M. botryoides candidum*. I have not seen any plant under this name, but from the description am led to think that it may be the same as a variety I have here as *M. b. carneum*. This has hardly a tinge of the colouring in it which could be indicated by the name *carneum*. The single flowers on the spike are large, and the spike itself is larger than the small-flowered *M. botryoides album*. I have a good many of these Grape Hyacinths, but one fears the names are far from reliable in any numerous collection.—S. ARNOTT.

ARRANGEMENT OF HOUSES FOR EFFECT.

THIS is often done in a formal style, quite contrary to Nature's plan, without any regard to contrasts of form and colour, which are absolutely essential where a miscellaneous collection of plants is found. If it be a large stove all the walls should be hidden with greenery, and the plan of having turf behind a screen of wire netting in which may be planted *Selaginella denticulata*, *Ficus repens*, *Adiantums*, *Nephrolepis*, *Nephrodiums*, *Begonia Rex*, and *Pothos argyrea*, with others is excellent. The roofs should be covered by *Allamandas*, *Bougainvilleas*, *Clerodendron Balfouri*, *Stephanotis*, *Ipomœa Horsfieldi*, *Passiflora princeps*, and others in variety, which must not be tied to the extreme tips, as is often done, but allowed to hang with freedom and grace to display their flowers as if growing in their own native woods.

The pillars should be clothed with such plants as *Gloriosa superba*, *Cissus discolor*, *Paullinia thalictrifolia*, or *Dipladenias*; while underneath open stages *Fittonias* and *Tradescantias* will thrive. There should also be sufficient plants for draping the extreme front of the stages, for which purpose *Panicum*, *Selaginella cæsia*, and *Tradescantia zebrina* are admirably adapted. The collection should be arranged as Nature arranges her trees, shrubs, and rocks, in masses of irregular outline and height. Noble foliage or specimen flowering plants ought to stand distinct, as princes amidst their peers, so as to give boldness and character to the whole.

The centre of the house must be the most prominent feature, as the focus on which the eye will rest from either end. There should be groups of colour and groups of greenery, and plants of arching and delicate outline will be found useful to break the formality of more rotund specimens. Of course the tallest plants will be at the back or the centre, as the case may be. But the great point is to avoid having a bank of plants as is often seen, as if someone had been using the shears so as to have everything exactly as we see a bank of clipped Laurels. White-leaved foliage plants should play a prominent part to lighten and break up more sombre hues, just as white flowers are used to prevent doubtful colours clashing. I think, instead of the dotting system or alternating plants, it is best to arrange them in small groups of threes or fives or even greater numbers, according to size. Then, instead of the eye wandering in bewildering amazement, it will be able to rest and take at a glance the design, proportion, and harmony of the whole.

In regard to conservatories or flowering houses the same general remarks are applicable, with the qualification that there will be less foliage and more flowers. All naked surfaces should be covered, pots must be hidden as much as possible, and other appliances for elevating the plants which sometimes becomes necessary. In addition to the remarks of contrast of form applicable to the stove we must have contrasts and harmonies of colours. Keep apart all shades of red, even in the case of pink and white in the same flower. Do not place near pink crimson, scarlet, or purple shades. Hues of magenta are very bad to arrange, as they appear to overpower all other colours. At the present time the semi-double Azaleas (which are to be preferred to the single, more spotted sorts) must not be mixed promiscuously, but each colour or shade alone. Hyacinths in the softer shades, as pink, blush, pale yellow, pale blue, and white, make a very pleasing group.

It ought to be borne in mind the two colours together must be contrasts; one must be vivid, whilst the other is soft and delicate. White being a neutral tint blends with any colour. The striking contrasts are red and green in their various shades, purple and yellow, crimson and yellow,

blue and orange, violet and yellow, the delicate shades of *Azalea mollis* together make a charming whole, but in mixing for harmony avoid dark shades of any colour, and have not less than three colours in harmony. I noticed a fine bed of Hyacinths in Regent's Park two extreme shades of blue in contrast—viz., Charles Dickens, dark blue, and Czar Peter, pale porcelain blue.

In arrangements for effect every branch, leaf and frond must have its place, and the hand should be used to relieve any overlapping. But at the same time our arrangements must not be too thin, because Nature, even in temperate climes like our own, is profuse and luxuriant. Plants flowering without leaves ought to be arranged rising as it were from a bank of greenery.—F. STREET.

PRIMULA CALYCINA.

THIS *Primula* has long been known in gardens, where it is often confounded with *P. Wulfeniana*, a totally different plant, and from which it is easily distinguished, even without the aid of flowers, by its longer and very irregularly margined leaves. It grows readily enough on the rockery in almost any position, but unless in exposed situations is rather a shy flowerer, and some can only manage to flower it by giving it a good roasting during the summer months, meanwhile supplying water very sparingly. It seems to prefer being wedged in between hard pieces of granite in rich, stiffish soil. It forms rosettes of long ovate-lanceolate leaves, of a half-weathered green colour, perfectly glabrous and shining, with a curiously wavy margin. The flowers are large, of a beautifully clear lilac, generally three or four together on short stalks, at the base of which are long linear bracts. The calyx is about an inch long with narrow bluntish sepals. It is a native of the Southern Alps, and usually flowers in May and June. This brief description with the woodcut (fig. 74) will no doubt be what "*Primula*" requires.

FORCED BEANS AND EARLY RADISHES.

ON the 21st inst. thirteen members of the Fruit and Vegetable Committee of the Royal Horticultural Society examined a collection of French Beans growing and bearing in one of the houses at Chiswick. About thirty varieties were grown under identical conditions. Five seeds of each were sown in 10-inch pots on January 15th, three pots of each variety. There was great diversity in growth and bearing. Some of the plants, such as the *Crimson Flageolet* or *Canadian Wonder*, with others not half so good, were considered, except under special circumstances, fully too tall, and certainly did not give such a good yield of pods as some of the dwarf and sturdier growers.

But while a few were regarded as too tall, considering the number of pods they produced, still more were too dwarf, several of these having a stunted appearance, and though the pods of some of them were numerous they were entirely too small for approval. Most of these diminutive varieties were sent from Germany, and, with one exception, are not in the least likely to find favour with British cultivators. There were a few of a similar character from France, but these on the whole were better, but did not reach the Committee's standard of usefulness—long, deep green, substantial, fleshy, brittle pods, and plenty of them. Mottled pods found no favour, one of the members of the Committee observing that if he took such to the French cook he had to supply the *chef's* shoulders would go over his head. Many varieties had waxy-yellow pods, but most of them miserably small, and only one stock merited recognition. Three marks—equivalent to awards of merit—were given to the following, whether any of the varieties had been previously honoured or not.

Veitch's Early Favourite.—A free yet sturdy grower, and good bearer of fine green pods. Ready April 14th.

Ne Plus Ultra.—Too well known to need description, and not easy to excel. Ready April 12th.

Osborne's Forcing.—Dwarf and free; an old favourite, not likely to soon go out of fashion. Ready April 12th.

Wythe's Improved Mohawk.—A free yet sturdy grower, and abundant bearer of large green pods. Ready April 14th.

Emperor William.—Very dwarf, with broad, flat, dark pods. The earliest of all. Ready April 1st. In contrast it may be stated that *Canadian Wonder* was not ready till April 19th.

Barr's Golden Wax.—A good grower and free bearer of long wax-like pods, distinct, and by far the best in its section.

It may be said that the maximum marks were granted unanimously except in the case of *Emperor William*, when they were awarded by 7 votes to 2. Some members appear to have been neutral.

[Pods of the six varieties named were placed before the Committee at the Drill Hall on the 27th inst., and awards of merit recorded.]

Another variety deserves mention—namely, *Covent Garden Early Negro*. Only a few seeds germinated, but some of the resulting plants produced such good and deep green pods that the Committee wished the variety to be tried again.

RADISHES—AN ADVANCE.

Growing in an unheated brick pit in the Gardens some half dozen varieties of Radishes were examined. Three of these were from France,

and for comparison were also sown the French Breakfast and a couple of First Early varieties from home stocks. The same quantity of seeds of each were sown in drills the same distance asunder on March 17th. During their whole period of growth the plants were exposed throughout the day, the sashes placed over them at night. The results of the small trial are particularly noteworthy, and without doubt two valuable new Radishes have now had their merits fully tested. These are what may be shortly termed *Vilmorin's Extra Early Olive-shaped Scarlet* and *Extra Early White Forcing*. These were grown in the Gardens last year and sent to the Drill Hall, awards of merit being granted for the samples.

On seeing them growing last week by the side of other standard varieties, the superiority of the two "*Extra Earlies*" from France was so manifest that *first-class certificates* were unanimously granted for them. Sown as we have said on March 17th, they were ready for use on April 21st. The others could not be ready for ten days, and some of them a fortnight after that date; and further, when they are ready

FIG. 74.—PRIMULA CALYCINA.

there will not be half the number of good Radishes that were produced by the "*Extra Earlies*." Nor is the difference due to any imperfection in the seeds, for they all germinated alike well. The gain in the one case, and loss in the other, is wholly due to the leafage of the plants.

The leaves of the certificated varieties, though stout, are very small, so much so that when expanded their surfaces were fully exposed to the direct action of light. Each leaf was thus able to perform its functions in the preparation and deposition of organised matter, and hence the quick formation of the fleshy bulb-like roots.

Very different were the leaves of the ordinary "*First Early*" varieties; they were and are four times the size, the inevitable result being a crowd and a crush, with consequent spoliation and total inability to provide the necessary material for the formation of the coveted bold crisp early Radishes. This is a little lesson which demonstrates the importance of sound unobstructed developed leafage—not in Radishes alone, but in everything.

The practical outcome of this small trial of Radishes, under absolutely the same conditions in every respect—time of sowing, soil, exposure, and distances of plants—is that the "*Extra Earlies*" represented a crop of at the least 100 per cent. greater value (and in fact a great deal more) than the later sorts.

As Radishes cannot possibly be too early these new extra early French introductions may be expected to find their way into most gardens, while growers of Radishes for sale will, if they are wise, give them a good trial at the earliest opportunity. They will yield far more bunches from a given area of land, at a decided earlier date, than the varieties usually grown, and in quality as good—at least, those were at Chiswick—as the most fastidious could desire.

There was another French Radish called the "*Leafless*," and nearly merited its name. The leaves are like diminutive abortions, yet produced early roots. It is a mere curiosity, but the two varieties certificated are serviceable acquisitions, and as such well worthy of the attention of cultivators.

ROSE SHOW FIXTURES FOR 1897.

- June 15th (Tuesday).—Ryde.
 „ 18th (Friday).—Portsmouth (N.R.S.).
 „ 24th (Thursday).—Colchester.
 „ 25th (Friday).—Maidstone.
 „ 26th (Saturday).—Windsor and Dorking.
 „ 29th (Tuesday).—Canterbury, Sutton, and Westminster (R.H.S.).
 „ 30th (Wednesday).—Croydon, Ealing, and Reading.
 July 2nd (Friday).—Crystal Palace (N.R.S.).
 „ 7th (Wednesday).—Glasgow, Hanley,* Hitchin, Reigate, Leeds,† and Tunbridge Wells.
 „ 8th (Thursday).—Bath, Gloucester, Harrow, Newcastle-on-Tyne, and Woodbridge.
 „ 13th (Tuesday).—Wolverhampton.†
 „ 15th (Thursday).—Norwich (N.R.S.) and Helensburgh.
 „ 17th (Saturday).—New Brighton.
 „ 22nd (Thursday).—Halifax and Trentham.
 „ 27th (Tuesday).—Tibshelf.

* A show lasting two days. † Shows lasting three days.

The above are the only dates that have as yet reached me. I shall be glad to insert in the next list any further fixtures that may be sent me, whether of Rose shows or of horticultural exhibitions where Roses form a leading feature.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

A "ROSE-DAY" PROPOSAL.

I HAVE seen in some paper a list of all the proposals which had been made to commemorate the Queen's Diamond Jubilee. They ran into hundreds, yet I boldly make another. It is a simple and sentimental proposal for the decoration of our persons on June 22nd. I think the British floral emblem—the Rose—should be worn by everybody on the celebration day.

The Rose crop will be in all its glory at the end of June, and no one need be without a bloom who has a penny to spend. I further suggest that June 22nd shall be always known as "Rose Day," in honour of England and good Queen Victoria. Yes! I think "Rose Day" ought to come. As the Poet Laureate says in his best prose work, "The Garden That I Love" (page 96), "The Rose is the typical flower all the world over, and the mind cannot get away from its representative personality. Withal in most gardens the Rose enjoys but a brief reign, and much briefer than that of many another flower. But so long as it blooms in profusion it throws into the shade all other pretenders." Just so. "Rose Day" would throw all other celebration days into the shade.

The Rose is a royal flower, and should be used on such a truly royal and national occasion this year, and for all time.—F. R. H. S.

ROSES UNDER GLASS.

ALTHOUGH these are now in full beauty, whether in pots or planted in the borders, there is much work to be done if the plants are to be kept clean and healthy, so as to give a useful second crop of flowers, and be in the best condition for early ripening, to form suitable plants in time for blooming through the coming winter.

It is the early pot Roses of spring that can be most readily brought into condition for winter flowering, and as it is useless attempting to bloom any but specially prepared plants in the dead of winter, a few words upon this subject may be seasonable. In the first place we need to pay some attention to selection of varieties. Very double Roses cannot be so successfully opened as those with fewer petals, and these last a long time during the winter, being far less evanescent than during the brighter and warmer days of early summer.

Isabella Sprunt, pale yellow; Safrano, apricot; Madame Lambard, red; Niphetos, pure white; Fiametta Nabonnand, white, carmine shaded; Général Jacqueminot, deep red; Sylph, white, tinted with peach; Papa Gontier, rosy crimson; G. Nabonnand, salmon and peach; Amazone, deep lemon yellow; Augustine Guinoisseau, pale blush white; and Souvenir de Wootten, very deep red; are twelve grand pot Roses for forcing.

Six good climbers are found in Maréchal Niel, golden yellow; Climbing Perle des Jardins, deep straw yellow; Climbing Niphetos, pure white; William Allen Richardson, orange and apricot; Reine Marie Henriette, deep crimson; and Madame Abel Chatenay, fawn pink shaded with salmon.

These more vigorous varieties can be grown in pots provided they are 8 to 10 inches across. When grown on the long rod system—i.e., cutting down the growths as soon as they have flowered, and encouraging more long rods from the base, there are few Roses which force with greater satisfaction. The main point is to secure well ripened wood, and if growth be hurried along until the early part of July the plants can then be removed to the open air and gradually ripened. We find it a good plan to stand the climbers, half-plunged, against an Arbor Vitæ hedge, securing the rods by stretching a wire or string around several plants, and fastening to the hedge.

Before placing the plants outside a dressing of soot is spread over the soil they are to stand upon. This prevents worms entering the pots.

Standing the pots upon pieces of slate does not answer so well, as it often happens that the pot fits closely, or a little soil causes stoppage of the drainage, and the pots become more or less sodden. It is very easy to place a board in front of the pots, and fill in between them with ashes, cocoa-nut fibre refuse, or other easily handled material. Half plunging of this description is a great safeguard against sudden drought, and protects the lower and most important roots. We need to keep them rather dry as soon as there is a natural cessation of growth, but to do this too suddenly, or allow them to become very dry one day and wet the next, is not calculated to secure an efficient ripening.

While in full growth liquid manure may be applied freely if weak, and will be far more beneficial than the same amount of stimulants given in stronger and less frequent doses. The same treatment applies to all pot Roses; we must grow them carefully, and not partly neglect them simply because the bulk of their present beauty is past.

There should be no need to repeat the oft-written advice respecting the great importance of early and prompt measures as regards our many insect foes. Shading will soon be necessary, but it should be very slight—just enough to break the glare of the sun is ample. Roses enjoy plenty of light, and it is only the burning power of sunshine through clear glass that we wish to check. A slight shade renders ventilation more easy and safe. We must give some air during this season, but it is most difficult to regulate when a few minutes' bright sun causes the temperature to rise 20° to 30°. Damping down is not sufficiently practised; a moist atmosphere is a great help during bright weather, and if a little liquid manure be used the ammonia feeds the foliage, imparts a healthy gloss, and is a great advantage all round.—PRACTICE.

CAMELLIAS AFTER FLOWERING.

THERE can be no doubt as to the important bearing the treatment of Camellias after flowering has upon future success. Next season's crop of flowers may be reduced 50 per cent., or entirely, simply through faulty methods of procedure at the present stage, and I propose giving a few notes that may be of assistance to those whose experience of these beautiful flowers is comparatively limited. I have been growing them for upwards of a score of years, and shall speak from practical experience.

When Camellias are not in flower they may be syringed frequently with advantage, and this generally keeps the foliage clean and healthy; but glutinous matter sometimes adheres to them, and syringing will not remove it, yet it is absolutely necessary to the health of the plants that it be removed, and it should be cleared immediately flowering ceases. Sponging is the surest way, using some simple mixture. Before beginning to sponge syringe the plants with water several times to soften the dirt, and during the operation of sponging the whole of the foliage must be kept constantly wet, as it is so much easier to remove the dirt when it is soft and wet than when hard and dry.

Equally important is having the roots in proper order. No Camellia should be planted out in a bed or border without the greatest care being devoted to the drainage, as it is only in the first place that this can be properly treated, and there is no easy way of rectifying the drainage of plants which are growing in a bed. Wherever the soil has become stagnant or in bad condition do not fail to examine and rectify the drainage. Planted-out specimens are very liable to suffer from being too much disturbed at the roots, and in trying to improve the drainage it can better be put round the sides than directly under the plant; and if the vacancy made to permit this is filled with good soil an improvement will soon take place. Firm soil is also necessary to the success of the plants; indeed they will not remain long in good health if the soil is loose. Seeing that the drainage is right and the soil firm should have annual attention as the plants cease flowering. The soil may be allowed to become slightly dry before beginning to work with it, but after the operations suggested are finished it must not on any account be permitted to become dry; and from the day the plants begin growing until the flower buds are well developed the soil at the roots must be kept constantly sweet and moist. In some cases the growth begins before the blooms are all over, but the main growth rarely commences until then.

Apart from cleaning the foliage in the first place, they should be frequently syringed with clear water afterwards, and once daily is not too often in good weather. I do not approve of keeping them very close, as the growths are liable to become very long and weakly, and this also applies to plants grown under a dense shade. We have not shaded a Camellia for many years, and we have always plenty of blooms from November to April. Besides the present being a good time to clean the foliage and to place the plants in a proper position for another year, repotting and planting may also be done.

Sometimes when plants are in bad health in pots their growers think they would do better if planted out, but my experience leads me to say that it is easier to improve a Camellia in a pot than when planted, and I should not be inclined to plant a specimen in a half-dead condition. The plan would be to get it into good health in a pot and then plant. The object of planting out is to secure large specimens which will require less attention in watering than those in pots, and probably all the finest in the country are planted out. Success is certain when good plants are used and the operation carefully performed, but all depends on that. The bed must not be less than 2 feet 6 inches in depth, and at least 6 inches of this should be taken up with carefully arranged drainage. A layer of fibrous turf may cover this. The plants need not be placed too deeply, and the whole bed filled firmly with a mixture consisting of equal parts of peat and loam to which has been added a liberal dash of

coarse sand. This mixture will suit Camellias under all conditions of culture.

The plants requiring potting may be divided into two classes, one being those which have outgrown the limits of their pots and need more root room, and the other those which have become sickly and failed to fill their pots with roots. The remedy for the first is to give them larger pots, and the best thing to do with the second is to turn them out, removing all loose or useless soil from their roots, and repot in smaller sized pots. There is no better way than this of improving sickly Camellias. All plants that are repotted must be shaded for a time, keeping the atmosphere in which they are placed very humid.

—M. P.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL, APRIL 27TH.

THE Drill Hall was not nearly so crowded on this occasion as has previously been the case, but the Show was, nevertheless, a very interesting one. Roses in the floral section were superb, while Orchids were of good quality, though the Chelsea specimens were much missed.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); with the Rev. W. Wilks and Messrs. J. Cbeal, J. H. Veitch, A. H. Pearson, R. Fife, J. Willard, J. Smith, F. Q. Lane, G. Wythes, J. A. Laing, G. Woodward, W. Bates, W. Farr, A. Dean, A. F. Barron, and J. Wright.

Messrs. Hurst & Sons sent heads of a new Broccoli, Hurst's Early April, creamy white, close and conical. No information accompanied them, and they were passed. Mr. W. M. Russell sent fruiting plants, also gathered fruits of Russell's Early Giant Strawberry, the result of a cross between La Grosse Sucrée and Noble. They were large, dark, and corrugated, but deficient in flavour, and no award was made.

Messrs. E. Hillier & Son, Winchester, sent fruits of a handsome dessert Apple, *Hillier's Easter Orange*. Fruits full medium size, conical, greenish yellow, but almost entirely covered with broken crimson stripes and strewed with dots, though some of these at least appeared to be of a fungoid character. Stalk half an inch long, slender, deeply set in a russet cavity. Eye rather small, partially open, with flat segments. Flesh tender and pleasantly flavoured. An award of merit was granted unanimously.

Mr. Owen Thomas sent from Windsor a fruiting plant, also a dish of fine clear fruits of his new yellow Tomato *Royal Windsor*. The flavour was considered excellent, and an award of merit was granted with unanimity. A new Strawberry, Sir Trevor, the result of a cross between La Grosse Sucrée and Royal Sovereign, was also sent by Mr. Thomas. Very handsome fruits, but some of them dark crimson with prominent seeds and scarlet flesh; others bright scarlet with whitish flesh, these being particularly good. The Committee thought the variety not yet fixed in character, and it will no doubt be seen again.

Mr. G. Wythes exhibited old and new Grapes Lady Downe's, old, firm and good; Black Hamburg and Foster's Seedling, new. The Black Hamburgs were well finished, and represented excellent produce, from Vines in pots; also boxes of superior fruits of Royal Sovereign and Keen's Seedling Strawberries, as well as St. John's Figs and meritorious vegetables (silver Banksian medal).

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. C. T. Druery, H. B. May, H. Herbst, R. Dean, G. Stevens, J. Hudson, J. Jennings, J. T. McLeod, R. B. Lowe, H. S. Leonard, C. Jeffries, J. W. Barr, C. E. Shea, J. D. Pawle, D. B. Crane, H. J. Jones, H. J. Cutbush, C. Blick, H. Turner, G. Paul, T. W. Sanders, O. Thomas, and T. Peed.

Messrs. F. Cant & Co., Colchester, arranged a semicircular group of Roses in pots. The plants were clean, healthy, and carrying brightly coloured substantial flowers. Several of the well known varieties were represented. Messrs. W. Cutbush & Sons, Highgate, sent plants of *Azalea mollis* interspersed with Ferns and Palms. Miscellaneous flowering and foliage plants came from Messrs. J. Peed & Sons, Norwood. *Ericas*, *Clivias*, *Cannas*, *Anthuriums*, *Lily of the Valley*, *Palms*, and *Ferns*, with a few *Orchids*, were included.

Messrs. Paul & Son, Old Nurseries, Cheshunt, sent splendidly grown Roses in pots. The varieties comprised *Innocente Pirola*, *Souvenir d'un Ami*, *Celine Forestier*, *Ulrich Brunner*, *Anna Olivier*, *Elsie Fugier*, and others. The same firm also sent alpine plants and cut sprays of flowering shrubs and *Amaryllis*. Mr. J. Wilson, Drewton Stray, South Cave, R.S.O., Yorkshire, staged a considerable collection of Daffodils, amongst which were many flowers of good quality. Messrs. J. Veitch and Sons, Ltd., Chelsea, staged baskets of *Cydonia Maulei*, *Exochorda grandiflora*, and *Andromeda speciosa cassinefolia*, with a splendidly flowered standard of *Cytisus scoparius præcox*. The Daffodils from Messrs. J. Veitch & Sons were of grand quality, the size and colour of the flowers being in many cases exceptional. Seedling varieties were also staged. Messrs. J. Balchin & Sons, Hassocks Nurseries, sent *Boronias* and *Coprosmas*.

Mr. Charles Turner, Royal Nurseries, Slough, staged a large number of varieties of *Primula Sieboldi*, the colours ranging from pure white to reddish purple. All the varieties were named. Alpine Auriculas in variety, *Calla Elliottiana*, and *Carnation Princess May* also came from Mr. Turner. Mr. G. Mount, Canterbury, sent some superb cut blooms of Roses, including *Maréchal Niel*, *Catherine Mermet*, *Ulrich Brunner*, *Niphetos*, *Général Jacqueminot*, and several others. Messrs. J. James

and Son, Farnham Royal, sent hybrid *Cinerarias* that were very interesting. The parents were *C. cruenta* and *Senecio Heritieri*. Plants of the beautiful *Arctotis aureola* came from J. T. Bennett Poë, Esq., Cheshunt. Flowers of *Tulipa Greigi* were sent by Messrs. R. Wallace & Co., Colchester.

Mr. H. B. May, Upper Edmonton, sent a number of *Coleuses*; and Mr. W. Rumsey, Waltham Cross, Roses cut and in pots. Foliage plants composed the major portion of the exhibit from Messrs. J. Laing and Sons, Forest Hill, though flowering plants were also contributed. Messrs. Barr & Sons, Covent Garden, made a brilliant display with single and double Tulips, staged also Alpine plants, and *Narcissi* in fine form. The firm's new variety *Victoria* was very conspicuous.

MEDALS.—**FLORAL COMMITTEE.**—Silver-gilt Flora, Mr. G. Mount, Roses; silver Flora, Messrs. Barr & Sons, Tulips; F. Cant & Co., pot Roses; Paul & Son, Roses and hardy plants; C. Turner, *Primula Sieboldi*; bronze Flora, W. Cutbush & Sons, plants; C. Turner, *Malmaison Carnation Princess May*; silver Banksian, J. Peed & Sons, plants; J. Laing & Sons, plants; W. Rumsey, Roses; and bronze Banksian, H. B. May, *Coleus*.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, De B. Crawshaw, R. B. White, W. H. Protheroe, H. J. Chapman, W. H. Young, F. J. Thorne, W. H. White, J. Jaques, T. Statter, W. Cobb, E. Hill, J. Douglas, S. Courtauld, H. Williams and H. M. Pollett.

Orchids were beautifully though not numerous shown by Messrs. F. Sander & Co., St. Albans. There were *Odontoglossum vexillarium* in variety, *Oncidium Marshallianum*, and others (silver Banksian medal). R. Brooman White, Esq., Ardarrock, Garelochhead, sent a superb collection of *Odontoglossum crispum* in variety, as well as *O. Andersonianum*, *O. Brassia*, and others (silver Banksian medal). Mr. Barrell, gardener to W. S. Ellis, Esq., Dorking, exhibited *Odontoglossum crispum* and other Orchids in fine form (silver Flora medal), as did Mr. W. Buchall, gardener to S. Cooke, Esq., Kingston Hill (bronze Banksian medal). Mr. A. Methven, gardener to the Marquis Camden, Bayham Abbey, sent a magnificent plant of *Dendrobium thysiflorum*.

CERTIFICATES AND AWARDS OF MERIT.

Auricula Fred Knighton (C. Turner).—An Alpine variety, with perfect golden paste. The colour is almost black, becoming lighter towards the edges (award of merit).

Lithospermum tinctorum (J. T. Bennett Poë).—A plant attaining to a height of about 10 inches, and producing pale blue flowers (award of merit).

Odontoglossum crispum heliotropium (R. B. White).—The varietal name of this crispum will convey an exact idea of the ground colour of the sepals and petals of the flower. The spots are chocolate brown (first-class certificate).

Primula Trailii (G. F. Wilson).—The flowers of this rare *Primula* are borne on footstalks about 9 inches in length. The colour is white (award of merit).

Rhododendron superbissimum (J. Veitch & Sons, Ltd.).—This is a hybrid, of which the parentage is not known for certain. The flowers are white, and occasionally very faintly suffused with rose. It has a delicious fragrance (first-class certificate).

Tropæolum Mrs. Sanderson (Mrs. Sanderson).—A dwarf, blackish crimson, free blooming form of splendid shape. The flowers are delicately perfumed (award of merit).

SCIENTIFIC COMMITTEE, APRIL 13TH.—Present: Dr. M. T. Masters (in the chair); Mr. McLachlan, Rev. W. Wilks, and Rev. G. Henslow, Hon. Sec.

Mushrooms Raised from Spores.—With reference to this subject, the following communication was received from Dr. D. H. Scott:—"Mr. Massee, of Kew, has referred me to what seems to be a thoroughly successful solution of the problem, how to raise Mushrooms from spores. Two French authors, Costantin and Matrachot, have raised five varieties true from spores, carrying on their cultures in sterilised food solutions, and subsequently on sterilised manure. The whole development is said to take from six to seven months."—"Comptes Rendus," vols. 117 and 118, 1893-4.)

Wireworms, Cure for.—With reference to this, discussed at the last meeting, Dr. Masters remarked that Mustard as powder, or dug in green, had proved to be effective in destroying this pest.

Daffodil with Frilled Corona.—Dr. Masters exhibited a blossom having this peculiarity, which occurs also on *Cyclamens*, *Primroses*, and the var. of *Chrysanthemum Mrs. Alpheus Hardy*. The structure of the fibro-vascular cords is peculiar in the Daffodil in having its elements reversed in position from those of the perianth itself. It was received from Mr. Dick of the firm of Messrs. Cooper, Taber & Co.

Anemone fulgens.—He also showed specimens of this flower from the Riviera, and also the Greek form with rounded sepals. Several of the former were becoming double just as is the case in South of France. Dr. Masters observed that the wild *Anemone*, *A. nemorosa*, had become double in his garden after some years' growth. Mr. Henslow added that the same had occurred with him; specimens originally single, received ten years ago from woods in Wiltshire, were now semi-double.

Larvæ of Bibio.—Mr. McLachlan observed that an error occurred in the statement about propagating soil containing the larvæ of daddy-longlegs, in the report of the meeting on March 9th. It should have been that of a species of *Bibio*.

Tulip Leaves Diseased.—Mr. Thos. Wannock of Polegate, Sussex, sent specimens of leaves showing discolouration. They were forwarded to Kew for examination.

Cineraria cruentus.—Mr. Herrin of Dropmore sent specimens of the original form of this plant exhibiting different shades of colour as well as a cross between it and the garden form. The latter was of a deep crimson tint.

Daffodils synanthic.—Rev. C. W. Dod sent two specimens, each consisting of two flowers, of which the stalks were fused for the entire length from base to flower; they were the var. *Empress*. He observes that in one case "the union was by a superficial membrane only; but in the other the combination was complete, the joint scape being hollow at the base, without any visible joining."

Earths.—Mr. Wilks brought specimens of this umbellifer, which is common in the woods and hedges and open hills about Croydon, the tubers being much eaten by children in that neighbourhood. He remarked that two, of the ages two and ten, had lately died, apparently poisoned by eating the leaves of some wild plant, but its nature could not be discovered.

BAMBOO CANES AND EARWIGS.

AS Bamboo canes are so much in request for training Chrysanthemums, I wish to draw attention to an evil in relation to their use that came under my notice, as the experience may prove useful to others. We grew about 300 Chrysanthemums for large blooms, and after the buds were taken we were much troubled by earwigs. We tried traps of every description to no purpose, and the ravages kept growing worse, even after the plants were housed. On going in with a light about 10.30 P.M., October 23rd, I chanced to see an earwig just vanishing into the hollow end of a Bamboo cane; the next day every cane was unloosed, and the occupants dislodged by a sharp tap on the floor; it was then we found what a splendid retreat the canes had afforded for the enemy. We succeeded in killing a small army of earwigs, and needless to say were troubled no more that season. I recommend all growers who use Bamboo canes for Chrysanthemums to cut the tops at a joint, or otherwise to plug them with wood or cement if they wish to save the blooms from the ravages of these troublesome pests.—J. C., Lancashire.

PUTNEY AND WANDSWORTH CHRYSANTHEMUM SOCIETY.

WE are informed that by way of celebrating the sixtieth year of Her Majesty's reign the tradesmen of Putney and Wandsworth will this year offer a silver cup, value 25 guineas, to be called the Putney and Wandsworth Tradesmen's Commemoration Challenge Cup, also handsome money prizes for cut blooms, open to all, at the annual show to be held in November.

HIGHGATE CHRYSANTHEMUM SOCIETY.

THE annual report and balance-sheet, together with the schedule of the next Show of the Highgate and District Chrysanthemum Society, has just reached us. The Committee's report is a gratifying one as showing the satisfactory condition of the Society, and proving the increased popularity of the annual Show. The 1896 exhibition brought so many exhibits that the Northfield Hall did not provide a sufficiency of space, and the overflow had to be relegated to a tent. We trust this year's display, which is fixed for Thursday and Friday, November 4th and 5th, will be equally as successful both floriculturally and financially. There are eighty classes scheduled, including many in which special prizes are very generously offered by ladies and gentlemen resident in the neighbourhood. The Secretary is Mr. W. E. Boyce, 20, Holmesdale Road, Highgate, N.

HULL CHRYSANTHEMUM SOCIETY.

THE motto of the Hull and East Riding Chrysanthemum Society has ever been "Onward," and during 1896 the Society as well as the several years since its inception still showed signs of progress. In the report that was read at the annual meeting occurs the following paragraph:—"The Committee heartily congratulate the members of the Society on the result of the last year's working. Not only has there been an addition to the roll of membership, and consequently an increase in the amount of subscriptions, but the public have manifested a much greater interest in the Society's proceedings. This latter fact is evidenced by the greatly increased attendance at the last exhibition held by the Society on the 11th and 12th November last; in fact, so great was the demand for admission on the second day of the show that, at one time, it was found necessary to close the doors until the congested state of the room had been somewhat relieved." Could anything more satisfactory than this be wished—except a larger building? Never have officials worked harder than those of Hull, where the whole scheme of arrangement is well nigh perfect. They have sought for success and they have found it, and it is more than probable that if present efforts are maintained

they will keep it. The Honorary Secretaries are Messrs. Edward Harland and Jas. Dixon, Manor Street, Hull, who will provide full particulars of the show to be held in November.

SOUTH SHIELDS CHRYSANTHEMUM SOCIETY.

WHEN the annual meeting of the South Shields and Northern Counties Chrysanthemum Society was held Ald. T. G. Mabane, President, occupied the chair. Mr. Bernard Cowan (Hon. Secretary) read the annual report, which stated that the balance in hand had been increased from 15s. 5d. to £26 5s. 9d., which might be considered as highly satisfactory. From the annual meeting held on the 22nd September, 1895, till November 25th, 1896, the Committee collected in subscriptions the handsome sum of £139 6s. 6d. This was gratifying as showing that the work of the Committee was appreciated in trying to hold successful exhibitions in the town. The last exhibition was scarcely so large as the previous one, but the high-class merits of the exhibits amply compensated for that deficiency. The Chairman observed that the report was most satisfactory. Last year they seemed to get low down, but they had fortunately been able to bring the Society up again. As our readers will probably be aware, the first show of the Society was held in 1882; and for the success that has been achieved since that time much credit is undoubtedly due to Mr. Bernard Cowan, who is an occasional contributor to our columns.

SHEFFIELD CHRYSANTHEMUM SOCIETY.

AT the monthly meeting held in the Society's rooms on the 14th inst., the second of three papers on the cultivation of the Chrysanthemum was read by Mr. Chas. Scott. The former paper commenced with the cuttings and treatment required up to the present time. The second portion, which was very clear and concise, fully explained the writer's treatment, dealt with the time for stopping the various sections of the group. He also gave instructions in watering, potting, the soil most suitable to use, and other essentials. The remaining portion of his cultural instructions will be given later in the season, when the series will have dealt with the annual life of the plant from the cutting to the exhibition flower in November, when the Society's shows are held. A large number of the members were present, and greatly appreciated the information given. A discussion followed, and a vote of thanks to the essayist brought the subject to a close. The exhibits were *Spiræas*, and a good number of fine plants were shown. In the professional section Mr. T. Dixon was first, Mr. Thos. Morton second, and Mr. Chas. Scott third. Amateurs, Mr. H. H. Welford first, and Mr. W. Donaldson second. Mr. John J. Newsham occupied the chair, and received a vote of thanks for his services.

CINERARIAS AT HOME.

AS so much seems to have been written lately on the culture of Cinerarias, it may perhaps interest your readers to know something of the manner of growth in their native haunts. During a prolonged stay in the Canary Islands I took particular note of these plants, and came to this conclusion—they are undoubted rock plants. I never once saw the tall *Cineraria cruenta* in the Island of Teneriffe. This species is undeniably the original parent of the greenhouse varieties, and the flowers, though of course not the size of our huge modern inventions, are by no means small.

In the Island of Grand Canary they grew in abundance upon the hills, but even on the mountains their tall showy flower heads were always to be discerned on the summit of cliffs, or on the raised banks on each side of the steep country lanes. In this last position, among the rough hedges of Prickly Pear and *Cytisus*, they flourished amazingly, growing to the height of 3 feet or more. The flowers varied greatly in colour; a pure white was to be found, but was far less common than those splashed or edged with blue, mauve, or purplish pink, or of selfs of various vivid shades of purplish crimson. Though the roots were generally shaded and protected by tall rough grass and herbs, the heads were always in full sunshine. I noticed only one curious exception, where many hundreds of these plants were growing on the face of a perfectly perpendicular cliff. So straight and rocky was it, that it was quite destitute of other plant life; but growing all down the precipitous lava rock were the Cinerarias, and though stunted and dwarfed to the height of a few inches, they appeared nevertheless green and healthy. These were in deep shadow at midday, but during the spring at least little trickles of water ceaselessly crept down the face of the cliff and kept the roots moist, for no roots could have penetrated into that iron-hard rock, while its surface was too steep and unbroken for any nourishing soil to lodge on it. I may add that this district is very wet during the winter and early spring months—their flowering season.

Though I never came across *Cineraria cruenta* in Teneriffe, in one region I found a variety of *Cineraria* infinitely more charming and refined. This only grew on steep rocky cliffs or banks of broken lava, and in the south and warmest side of the island. It was never more than 6 or 8 inches in height, and few flowers crowned the stem; its leaves, unlike those of its cousin of the Grand Canary, were not coarse and weedy looking, and its fixed colour was a soft and pleasing shade of pink; and though far from uncommon in the neighbourhood, I hardly ever saw it elsewhere. Unfortunately I made no note of its correct botanical name, though enlightened by an enthusiastic plant hunter, who declared it to be an exceedingly rare species, but I can find no mention of it in "Nicholson's Dictionary."—NOTA BENE.

"JOURNAL OF HORTICULTURE" EDITORIAL DEPARTMENT.—
From the present date, and until further notice, it is particularly requested that all letters and parcels intended for the Editor, also all communications for insertion in the "JOURNAL OF HORTICULTURE," be addressed to 8, Rose Hill Road, Wandsworth, London, S.W. N.B.—Business letters and advertisements must be addressed to the City Office.

— WEATHER IN LONDON.—During the latter part of the week ending on the 24th the winds were very cold, and were occasionally accompanied by driving rain. Sunday was bright but rather cold, but Monday was warm and summer-like. There was a heavy mist on Tuesday morning, which was maintained in a lesser degree the whole of the day, which was rather close and muggy, culminating in a heavy thunderstorm. Rain fell in torrents, the earlier drops being of enormous size. Wednesday opened very close and wet, becoming finer after midday.

— NATIONAL AURICULA SOCIETY.—The northern show of this Society will be held on Saturday next in the Free Library, Middleton, near Manchester. The usual classes are scheduled, and we trust the exhibition will be a success.

— TULIP SHOW.—Owing to the late cold weather having kept back the flowers, the Show of the National Tulip Society, which had been announced to take place in the Botanic Gardens, Regent's Park, on May 5th and 6th, has been postponed to the 12th and 13th.

— BERLIN.—The great exhibition to celebrate the seventy-fifth anniversary of the Horticultural Society of Prussia will be held from April 28th to May 9th. It promises, we are informed, to be one of the greatest shows of the year, and visitors to the Hamburg Show—which opens on the 1st of May—should extend their journey to Berlin. Roses, floral arrangements, forced vegetables, as well as garden projects, will be represented, and a very beautiful display is anticipated.

— MAGNOLIA SOULANGEANA.—A large plant, 12 feet high and 12 feet through of this beautiful Magnolia may now (April 19th) be seen in full flower in the Azalea garden at Kew. Of hybrid origin, it owes its parentage to *M. conspicua* crossed with *M. obovata*. In habit and colour of flowers it is intermediate between the two, for whilst it has the height of *M. conspicua* it has the more slender habit of its other parent. The flowers are produced with extraordinary freedom, the plant each year being covered with blossoms, which continue to expand for several weeks; in fact, at almost any time during summer a few flowers are to be found. They are large, and when fully expanded measure 7 inches across. The inside of the petals is white, the outside a light shade of purple. Flowering two or three weeks later than *M. conspicua* it is not so likely to be injured by frost. A warm position should be given, as cold cutting winds soon turn the edges of the petals brown.—W. D.

— THE LATE DR. HOGG.—The last portrait of Dr. Hogg, which appeared in the *Journal of Horticulture* on page 233, March 18th, was taken in the photographic department of that gigantic and varied supply organisation, the Army and Navy Stores, Victoria Street, Westminster. The character of the portrait impressed the heads of the department, and it was thereupon enlarged to practically life size for exhibiting in the Stores' collection as an example of high and effective artistic work. Mr. Henry J. Pearson of Beeston, member of Council of the Royal Horticultural Society, and an attached friend of the deceased gentleman, paying a casual visit to the Stores, happened to pass through the department in which the portrait was displayed. His quick eye detected it, and with prompt Pearsonian decision he secured it for presentation to the Royal Horticultural Society, and it will shortly occupy a position, with other worthies, in the Council room of the Society. It is a magnificent representation, in carbon, a splendid example of photographic art, a true and striking likeness, practically imperishable. It is somewhat remarkable that this, the only portrait of its kind, should have been discovered so unexpectedly by Mr. Pearson, whose father was one of the oldest and most esteemed of the Doctor's personal friends.

— THE LATE W. G. HEAD FUND.—This has now been finally closed, and the balance, after payment of medical, funeral, and other accounts, has been handed to the widow.

— SCHIZOCODON SOLDANELLOIDES.—My friend Mr. Wolley Dod, at page 339, suggests that *Schizocodon soldanelloides* would be likely to succeed in my garden at Wisley. I am happy to say that through the kindness of a gardening friend a plant is already growing there alongside of *Shortia galacifolia* and *Galax aphylla*, and appears to be thriving.—GEORGE F. WILSON.

— EARLY TOMATOES.—I felt much interested in a paragraph in last week's *Journal of Horticulture* (page 338) describing the Tomatoes grown at Mrs. Rylands' establishment, Isle of Wight, wherein your correspondent "S. H." says, "The fruit was well shaped and highly coloured." Will he give us a little more information through the Journal, and say when the seed was sown to have them ripe now, or whether the plants were from cuttings, and at what temperature they had been grown?—G. R. FEERLESS.

— TRENTHAM SHOW.—For eight years there has been a splendid show held under the auspices of the Trentham and Hanford Horticultural Society, and on July 22nd in Trentham Gardens there will be a ninth. Prizes amounting to a total of £400 are offered in the 103 classes scheduled. The principal class is for a group of miscellaneous plants, in or out of bloom, arranged for effect, occupying space not exceeding 300 square feet, and in this the prizes are £20, £18, £13, and £9, with the addition of a silver cup value 10 guineas. Roses and Carnations are encouraged by generous prizes, while fruit and vegetables are by no means forgotten. The Secretaries are Messrs. L. T. Alford, Hanford, and J. P. Jones, Hanford.

— PYRUS FLORIBUNDA.—Of the many species and varieties of *Pyrus* which are cultivated solely for their decorative value, this Japanese species is certainly one of the best. It flowers about the end of April or early in May, the rosy red flowers being produced in great abundance on spurs or young wood all over the plant. The blooms are followed by a large quantity of small yellow fruits. The habit of the plant is more that of a dense bush than a small tree with somewhat pendent branches. Several varieties of this species are in cultivation, noticeably *P. floribunda* var. *atrosanguinea*, with flowers much darker than those of the type, and *P. floribunda* var. *fl.-pl.* with semi-double flowers, both being desirable plants. Given some good soil to begin with, and a fair quantity of room, this plant gives little or no trouble, and may be counted on to produce a glorious display of flowers at the time previously mentioned.—W. D.

— SALE OF BOTANICAL BOOKS.—Messrs. Sotheby, Wilkinson and Hodge recently sold the library of the late Mr. F. C. S. Roper, F.L.S., which consisted chiefly of valuable works on botany and other branches of natural history. The more important of the botanical books were:—Cooke's "Illustrations of British Fungi," eight volumes, £17 5s.; "The Grete Herbal," printed at Southwark by P. Trenewell 1526, a sound copy, £39; Saccardo's "Sylloge Fungorum," £27; "Journal of Botany," from 1863 to 1896, £21; Sowerby's "English Botany," 1790-1863, with the Rev. J. M. Berkeley's appendix volume on British Algae, £36; a set of the same work, third edition, 1863-92, £15 10s.; "Bryologia Europaea," a work on Mosses by Bruch, Schimper, and Gümber, 1836-64, £18 5s.; a set of the Ray Society's publications, from the commencement in 1845 to 1893, was sold for £28. The total sum realised for the 668 lots, says a contemporary, was £1308 15s.

— GRAND YORKSHIRE GALA.—The schedule of the thirty-ninth annual Show of the Grand Yorkshire Gala Floral and Musical Exhibition has come to hand from the excellent Secretary, Mr. C. W. Simmons. This Show has come to be regarded as one of the finest in the country, and the Committee is ever desirous of adding fresh features or improving old in order to insure a maintenance of such a reputation. This year several hundred pounds are offered in prize money in the ninety-five classes specified in the schedule. In the first-class scheduled £58 is credited for a group of miscellaneous plants, in or out of bloom, arranged for effect, and occupying a space not exceeding 300 square feet; while a total of £42 is offered for ten stove and greenhouse plants. A commemorative class, to be called the Victoria prize, for a group of Orchids in bloom, with prizes of £20, £15, and £10, should attract strong competition. In addition to these £40 are offered for a table of ripe fruits, with generous prizes in the many other classes. Full particulars and schedules may be had from Mr. C. W. Simmons, Harker's Hotel, York.

— BIRMINGHAM AMATEUR GARDENERS' ASSOCIATION.—The fourth annual report of this Society shows a satisfactory state of affairs. Several exhibitions have been held during the past year, which have proved very successful, sufficiently so to warrant the Committee in giving equally as many in 1897. The balance-sheet shows a creditable sum on the right, which it is hoped will be increased in the future. The Hon. Secretary is Mr. W. B. Griffin, Wychbury, Alcester Road, Moseley, who will give all needful information.

— TREATMENT OF APPLE SCAB.—The series of experiments made at the Delaware Agricultural Station last season shows that with three applications of Bordeaux mixture the yield of first grade fruit was increased, says an American contemporary, fivefold over that of trees not sprayed. Two varieties of Apples were sprayed for the second season with Bordeaux mixture. The results show (1) that three applications made before blooming, after the bloom had dropped and when the fruit was the size of peas, gave as good results as when an additional spraying was made two weeks later; (2) that spraying increased the yield from three to thirteen baskets per tree; (3) that the amount of first-class perfectly smooth fruit was increased from 18 to 89 per cent.

— BERBERIS STENOPHYLLA.—Of the many species and varieties of Berberis known to cultivators this is certainly one of the best. It possesses a habit peculiarly its own, and when mature it is often from 8 to 10 feet in height by the same or more in diameter. The branches are thin, pendent, and covered with narrow dark green leaves three-quarters of an inch in length. The flowers are orange in colour, about a quarter of an inch across, and thickly produced along the whole length of the previous year's growth, and on short spurs of the old wood. The leaves being evergreen make it a welcome addition during winter to the shrubbery. Cuttings can be rooted readily if put into a cold frame in autumn in sandy soil and kept close for the remainder of the year. Plants $2\frac{1}{2}$ to 3 feet high can be grown in two years from cuttings, and in this stage are useful for beds. As a specimen plant for the lawn this shrub has few equals, as in addition to its free flowering qualities it is sweetly scented, and the habit of the plant is all that can be desired.—W. D.

— GUERNSEY GROWERS' ASSOCIATION.—The Year Book of this amalgamation of Channel Island Growers, which has for its object "Mutual help and protection," reaches us from the Hon. Secretary, Mr. Andrew Marshall. It is a comparatively large publication, having 128 pages enclosed in paper covers. The bulk is taken up by the advertisements, of which the Guernseyites appear to know the value; but there are besides several admirably written articles from practical men. For example, Mr. A. Collette discourses on "Manures," while hardy spring flowers, modern dairy farming, grading and packing Guernsey produce are ably dealt with. Tables are also given of freight charges by the Great Western and South-Western Railway Companies to London, and several of the provincial markets. There is in addition a table of the exports of packages of fruits, flowers, and vegetables, which have increased from 138,508 in 1883 to 1,403,945 in 1896, or an increase of over $1\frac{1}{4}$ million packages in fourteen years. This looks like real business. The price of the Year Book is 1s, and it may be procured from Mr. A. Marshall, St. Julian's.

— FORSYTHIAS.—If a list of the six best early flowering hardy shrubs were asked for, the Forsythias would find a place. Of easy culture and suitable for growing in almost any soil or position, they are deservedly popular. Although several specific names are found in some catalogues all can be sunk into two species and one variety. These are *F. suspensa* and *F. viridissima*, Chinese species, and a hybrid between the two known as *F. intermedia*. For variety of purposes and elegance of habit *F. suspensa* is certainly the best. Whether grown as a trailing plant to cover fences or arbours, as an odd plant in a mixed collection, or as a mass on the open lawn, it is equally effective. If the plant can be allowed to ramble over a Holly or other evergreen, the bright yellow flowers produce a most pleasing effect. After flowering it is a good plan when grown in beds, to cut all the growth back to a few eyes, long strong flowering wood is then produced. The flowers of this usually begin to open about the end of February. *F. viridissima* forms a bush usually 4 or 5 feet high, it flowers very freely, and is about a fortnight later than *F. suspensa*; the habit is stiffer. The name of *F. intermedia* exactly describes the last of the three plants, as in habit it is intermediate between its parents. It is not so well known as the other two, but is well worth growing largely. Like the others this has yellow flowers.—K. R. K.

— WAKEFIELD PAXTON SOCIETY.—From time to time we have published brief paragraphs relative to the doings of this admirable Society. From these references readers will have gathered how broad is the range covered by the essays read at the weekly meetings, though the subjects never go entirely beyond the kingdom of gardening. We have now before us the twentieth annual report, from which ample testimony of the utility and prosperity of the Society may readily be gathered. Membership reaches the handsome total of 285, and fifty-one meetings have been held during the past year, at which there was an average attendance of fifty-four. The library, consisting of almost 500 volumes, is very greatly appreciated by the members.

— SHORTENING BACK OR PRUNING HARDY FRUIT.—About this time last year I cut back some of the leading top shoots of Marie Louise, Beurrié d'Amanlis, and Doyenné du Comice Pears against a wall in my garden. I did so with the intention of diverting the sap from this top growth to the fruit buds underneath. Whether my action had anything to do with it or not—I am anxious to learn—most of the fruit buds fell off. Would some of your experienced readers say whether spring pruning just now would be likely to have such a result generally on outdoor fruit, Nectarines, and Apricots included?—W. J. MURPHY, *Clonmel*.

— PONTEDERIA CRASSIPES.—This plant, known also as the Water Hyacinth, has been naturalised in some of the rivers of the Gulf States of America, and has increased so rapidly that it covers the surface of the water for great distances. In the St. John's River, Florida, and in some of the canals about New Orleans it is difficult for steamers to work their way through this raft of vegetation, and when they do the plants close in behind the boat and occupy the surface completely as before. The obstruction to navigation has become so serious that an appropriation of 10,000 dollars has been made by the Senate of the United States to enable the Secretary of War to study means of freeing water courses from the plant.—("Garden and Forest.")

— "FAMILIAR WILD FLOWERS"—Many of our readers will know and appreciate the excellent work published some time ago by Messrs. Cassell & Co. The present edition, by the same competent author, F. E. Hulme, F.L.S., is different from its predecessor inasmuch as the price is only 6d. per part, of which the work will be complete in twenty-one. It will comprise 200 full page coloured plates, from which it will be a comparatively simple matter to name several of the many wild flowers that beautify our hedgerows, brighten our woods, and adorn our fields. The text accompanying the illustrations is written in that pleasant style which makes technical matter readable, and even attractive. Everyone interested in wild flowers should procure this book, of which the first part was published at the end of February.

— CHESTER SHOW.—On July 28th and 29th the City of Chester will be *en fête* for the second annual exhibition. There are in the schedule now before us upwards of 150 classes, divided in the following sections:—Open to all; nurserymen only; amateurs and cottagers. The value of the prizes varies very largely both in the divisions and the classes, but an excellent display is practically a certainty. The sum of £55 is offered in the open class for a group of plants in or out of bloom, arranged for effect in a space of not more than 300 square feet, and this should bring strong competition. For a decorative display of ripe fruit 40 guineas are divided between first, second, third, and fourth, while for vegetables the three prizewinners have to be content with £10 in the proportions of £5, £3, and £2. The Secretary, from whom all necessary information and schedules may be obtained, is Major Walker-Jones, 6, Grosvenor Chambers, Chester.

— AMERICAN BOTANICAL LABORATORY.—Professor D. T. MacDougal writes to "Science" that the project for establishing a botanical laboratory in the American tropics has made such progress that a commission has been organised for the selection of a site for the proposed laboratory and for ascertaining how far the co-operation of American and British botanists can be enlisted in the scheme. The commission will select a location conveniently placed with reference to towns or settlements and in easy connection with a marine sub-station, and yet near the presence of a body of undisturbed tropical vegetation. The American members of the commission are Professor Douglas Campbell, of Stanford University; Professor J. M. Coulter, University of Chicago; Professor W. G. Farlow, Harvard University; Professor D. T. MacDougal, University of Minnesota. The Committee will be ready to make an informal report to the American Association at Detroit, and the British Association at Toronto, at their meetings in August.—("Garden and Forest.")

— **ANTHOLYZA ÆTHIOPICA.**—This is a showy bulbous plant, common, says a writer in a transatlantic contemporary, in the gardens of Southern California, and it blooms freely during the winter months. It belongs to the Iris family, and produces a spike of flowers with foliage like that of *Gladiolus*. It is a native of South Africa, and is commonly known in gardens by the name *Watsonia*, a nearly related genus. The spike of flowers is generally over 4 feet high, with as many as thirty flowers of a dull brick colour or Chinese red, the prominent anthers and markings in the divisions of the corolla of a deep maroon. The flower is more than 2 inches long, and nearly an inch across.

— **DOUBLE DAISIES.**—Although we obtain these freely from seed yet is the product rarely satisfying, as sowing to secure doubles we like to have the flowers as fully so as possible. So far from producing good bedding effects in the spring the Giant White and the rich King of Crimsons have proved to be the very best. I do not overlook Mr. Cannell's very fine white The Bride, but include it amongst the Giant Whites. I saw the other day a very pretty soft delicate pink flowered double that I much admired, but there were very few plants of it. It is the best of that hue I have seen. Some years ago there was a large variety of Daisies in commerce, but many of these, including the pretty *aucubefolia*, seem to have died out. As hardy carpeting or clamping flowering plants in the spring double Daisies deserve wider culture.—A. K.

— **THE GOLDEN-TIPPED STONECROP.**—This is one of the very hardiest of plants, as indeed all the Stonecrops are; but it is more, for in the late winter and spring it is of all the family the most effective. I grew it many years ago. When recently over in Middlesex I came across a huge patch of it, every tip of the mossy growth being creamy white, and presenting a very striking feature in the nursery. For vases or rockwork, where in conjunction with similar hardy plants it can grow untouched, this *Sedum* is at home. Still it can be got into good sized clumps by dibbling out pieces 10 inches apart in the spring. After the variegation is over, and by the autumn, these pieces will have developed into clumps several inches across; then lifted with a spade, and placed on loose soil and gently pressed in, they furnish very acceptable life and colour in late winter and spring.—D.

— **LEEDS FLOWER SHOW.**—Headingley Athletic Grounds bid fair to be *en fête* on July 7th, 8th, and 9th, on the occasion of the Leeds annual flower show and gala. There are so many excellent gardeners around Leeds, and, indeed, all over Yorkshire, that a magnificent show should reward the Committee for its enterprise in offering such handsome prizes as it has done in several of the six dozen classes scheduled, some of which are open and others restricted. The sum of £36 is offered in an open class for a group of plants arranged for effect, while half that amount goes to a group for amateurs residing within seven miles of Leeds. Six stove and greenhouse plants take £9 10s., and half a dozen Orchids in flower £10. Then there are Rose classes both for cut blooms and plants in pots, while fruits are also generously remembered. Growers who would like to compete should write for all particulars to Mr. W. B. Pindar, Middleton, Leeds.

— **CURRENTS AND PATRIOTISM.**—Rather a strange conjunction this, one might be tempted to say, but that the one affects the other to-day must be admitted. In Greece the Currant crop is one of great importance, and the Greeks, fired with patriotism, are to a man in arms against the Turk and in favour of the Cretan. Admitting this, it naturally follows that the growers of Currants, and the men who prepare them for market, as well as those who see to their sale, have had to give up fruit culture and take to the field of war. "Pity 'tis, 'tis true;" the Currant crop has to be left to itself—to be matured, sold, and sent away to, amongst other places, the United Kingdom. This means, that unless gentle peace quickly returns the year's crop will be valueless, and the gallant little country a loser—a loser where it can least afford to lose—and English matrons will greatly miss the universal favourite, the juvenile consumers of puddings will by this remember the year of grace 1897. True, all Currants are not grown in Greece, nor do all puddings contain Currants, but Greek Currants, like Currant puddings, are universal favourites, and the loss will be felt by an extensive, if juvenile, army of consumers. The attention of buyers is being drawn to the possibilities of the Greco-Turkish embroglio by circulars emanating from the larger dealers in foreign and colonial fruits, fresh and dry, and it is well, we think, to make a note here of the state of things now existing in Greece as possibly affecting the supply here, and price, of our humble but excellent friend, the Greek Currant.—("Gardeners' Chronicle.")

— **NATIONAL VIOLA SOCIETY.**—The annual Show of this Society will, as was the case last year, be held in the Royal Botanic Society's Garden, Regent's Park, and the date fixed is Saturday, July 17th. There are open and amateurs' classes to the number of twenty-five, while special prizes are offered in three classes beyond. Gold, silver, and bronze medals are offered for a collection of *Violas* as well as for a collection of Pansies, but with one exception all the remainder are money prizes. The Society is doing good work in arousing and increasing the interest in these very beautiful flowers, and it is to be hoped that the Show will be an unqualified success. The Hon. Secretary is Mr. A. J. Rowberry, The Crescent, South Woodford, Essex.

— **IRISH POTATO CROP.**—The total produce of the Irish Potato crop in 1896 was 2,701,000 tons, as compared with 3,472,015 in 1895. The yield per acre in the two years was 3.8 and 4.9 tons respectively. The average crop in the years 1886-95 was 2,744,963 tons, and the average yield in these years 3.6 tons. The Champion still continues to form by far the largest proportion of the Irish Potato crop, but the quantity, as compared with other kinds, continues to show a continued tendency to decrease, which seemed to set in after 1893. This variety in 1896 formed 75 per cent. of the total crop, against an average during the ten years 1884-93 of 79.3 per cent. The Champion was first introduced in quantity into Ireland after the failure of the Potato crop in 1879. The average price for Potatoes in Ireland, says a contemporary, was 2s. 1½d., or the lowest since 1891.

— **THE YELLOW ROOT (XANTHORRHIZA APIIFOLIA)**—Although perhaps of more botanical than horticultural interest, this little shrub is worthy of mention, especially when (as this season) it is in flower by the middle of March. Its nearest allies among hardy shrubs are the Clematis and the Moutan Pæony, a relationship of which its general aspect gives but little indication. It is a deciduous plant, and only grows 2 feet to 3 feet high. Its leaves are pinnate, and the flowers, which appear before the leaves at the end of each branch in erect compound racemes, are small, but numerous, each one a quarter of an inch in diameter, and of a dull, lurid purple. The species (which in itself constitutes a genus) is a native of the South-eastern United States, and has been in cultivation 120 years. The popular name of Yellow Root refers to the colour of its thick creeping roots, which in bygone times furnished the Red Indians of North America with a yellow dye. The plant has also some medicinal value as a tonic.—("Garden.")

— **KALOSANTHES CULTURE.**—The *Kalosantes* is a most useful sweet-scented summer-blooming plant. It may be grown into large specimens for exhibition, or in 48 or 32-size pots for the decoration of the conservatory. The cuttings should be taken now and inserted singly in small 60-pots; place them in an intermediate temperature, when they will soon root. Transfer them into larger pots, employing a compost of two parts turfy loam, one of peat, and one of leaf soil, with a good sprinkling of silver sand to keep the soil open. As the season advances place them in a cold frame or pit, and close early to encourage free growth. Stop them twice during the season to make them bushy. In the autumn place them in a light airy house and gradually withhold water, which will cause them to form flower buds. If extra large plants are required do not let them bloom, but pinch the points out and shift into larger pots. Whilst the flower buds are opening ventilate freely, which will improve the colour. Some growers place their exhibition plants in the open air whilst the flowers are opening; but they are protected from wind and wet, and shaded from bright sun.—GARDENER.

— **QUEENSLAND.**—In these days, when so many men of all classes, tired of the strife and strain of commercial life, are turning naturally for relief to the land and its quieter pursuits, we hear in this connection too much of England's expensive and overcrowded acres and too little of the millions of cheap, rich, sparsely settled lands of our colonies. In the matter of fruit-growing, for instance, Queensland offers particularly strong inducements to the small capitalist-cultivator. The soil produces readily, on the coast, every tropical fruit, and on the high table-lands every product that is grown in the temperate zones. For these, as has been said, there are good and growing local markets, while facilities for export to the United Kingdom are ever on the increase. Amongst the fruits that may be profitably raised the Banana takes a foremost place. This is a fruit which crops plentifully and soon, grows nowhere in the world better than in Northern Queensland, and the land needs little preparation for it. The prospects of Queensland as a fruit-growing country are, in fact, exceedingly bright, and good openings for fruit-growers with energy and a little capital are to be found there.

LYCASTE SKINNERI.

FROM time to time records of the successful culture of this handsome Orchid, occasionally accompanied by illustrations, have appeared in the pages of the *Journal of Horticulture*. We now present another one (fig. 75), of which the photograph was sent by Mr. H. Martin, gardener to Lord Leigh, Stoneleigh Abbey, Kenilworth. That the specimen is a splendid one will be seen by a glance at the illustration, but the following brief particulars sent with the photograph will probably enhance the interest. The plant is growing most luxuriantly in a 24-sized pot, and carried when at its best twenty-five fully expanded flowers. We are indebted to Mr. Martin for kindly sending the picture, and trust that he will shortly be able to send particulars as to the treatment to which the plant has been subjected.

NOTES ON LÆLIAS.

THE plants in this genus do not differ much from the nearly related Cattleyas in botanical structure, the chief distinction being that they possess eight pollen masses to each flower, while the latter have four only. They are not so numerous as Cattleyas, but the variation in them is very considerable. Some, like *L. Perrini*, *L. purpurata*, and others, are very much like the labiata section of Cattleya in habit and inflorescence; others are of small stature, and produce many-flowered racemes, such as *L. anceps* and *L. autumnalis*, while again there is a section of the genus with somewhat stem-like pseudo-bulbs, as *L. cinnabarina* or *L. harpophylla*.

Obviously, then, a collective mode of treatment will not do for them, and each species must, to a certain extent, be considered separately. In *L. cinnabarina* we have one of the most beautiful examples of an orange-scarlet Orchid, the long many-flowered racemes having a most exquisite appearance grouped with other and more quietly tinted kinds. It grows about a foot in height, the pseudo-bulb being one-leaved, the racemes appearing at the apex of these. To grow it well it should have the lightest position in the Cattleya house, and be potted or basketed in a rough open compost, consisting of peat fibre and sphagnum moss in equal proportion.

The drainage must come in for especial attention, and a fairly good layer of material may be allowed provided plenty of rough crocks and charcoal are mixed with it. A smaller habited plant, though not unlike the last-named in habit, is *L. flava*, and this is not by any means as well known as it deserves. On healthy plants the spikes carry five or six flowers to each spike of a bright golden yellow. Its culture consists of growing it somewhat freely during the summer months, and keeping fairly dry until the flower spikes appear. A thin compost suits it best, and it should have an airy, light position.

L. grandis is a pretty plant, but is now almost eclipsed by its well-known variety *L. g. tenebrosa*. The latter is sometimes labelled as a species, and is undoubtedly one of the most beautiful and generally useful Orchids in cultivation, ranking with such superb things as Cattleya Mossiae or *Lælia purpurata*. It delights in plenty of heat and moisture, and the roots being very large and fleshy the compost may be of substantial texture, but made very open and freely drained. Good peat, broken in large rough lumps, with only about a third part of sphagnum, will do it well, and the roots must never be dried summer or winter.

A peculiarity of *L. grandis tenebrosa* is that sometimes it blooms upon the young wood in autumn like Cattleya labiata, but usually it rests in sheath during the winter, and pushes up in spring and early summer. It varies very much both in size and colour, but the usual tints are purplish brown upon the outer segments, the lip purple and rose. *L. harpophylla* is another richly tinted kind, not unlike *L. cinnabarina*. When healthy it is easily managed and free in growth, doing well in the Cattleya or Mexican house. The pots need not be large, nor should a great thickness of compost be employed. It is very apt to be attacked by the soft white scale insect, and this must be rigorously kept under if the best results are to be attained.

Where there is room for large specimens to fully develop themselves *L. superbiens* is a very fine and noble plant. It has large, erect, fusiform pseudo-bulbs, each carrying a pair of long leathery green leaves from between which the immense panicles of flowers issue. The stems grow to a height of about 5 feet on

medium-sized plants, and each carries from a dozen to twenty blooms. The ground colour of these is a rich rosy lilac, the lip being much deeper than the sepals and petals, and lined with yellow and purple. As noted above, a large house is necessary for this, and the plants being vigorous rooters should be grown in large well-drained pots, the compost consisting of lumps of peat as large as a hen's egg, plenty of rough nodules of charcoal and crocks, and a little chopped sphagnum. *L. superbiens* is a rather straggling plant if allowed its own way, but by notching the rhizomes occasionally to make them produce back breaks they will become much better furnished.

All those mentioned are now flowering, but the most gorgeously beautiful of all is not open as yet. I need hardly say I refer to *L. purpurata*, which in its best forms ranks second to none. The flowers are too well known to need description, and the species is free in growth and easy to cultivate. The earliest plants to flower generally have time to form a new pseudo-bulb and sheath before winter, but if the later ones can be induced to rest until early spring they then come away with surprising vigour and flower freely. By no means endeavour to force them to do so; better by far let them have their own way, but if they seem inclined to rest keep them as quiet as possible in a slightly drier atmosphere until the turn of the new year.—H. R. R.

PLANT CONSTITUENTS: SODA.

OF the twelve primary constituents found in plants—namely, water (hydrogen and oxygen), carbon, nitrogen, phosphoric acid, potash, lime, iron oxide, magnesia, sulphuric acid, silica, soda, and chlorine, ten only are considered by chemists to be indispensable for the production of the majority of farm and garden crops, the last two—soda and chlorine—not being required. Nevertheless both enter into the composition of plants grown for their useful produce, such as grasses and cereals, Clover and legumes, fruits and vegetables, and unquestionably serve some useful purpose in the economy of the several plants.

Sodium, Na, 23, is a soft yellowish metal, first isolated by Sir Humphrey Davy in 1807. It does not occur in nature in the elementary condition, but its compounds are widely distributed through the crust of the earth and in the waters of the ocean. Sodium burns with a brilliant orange-yellow flame, yielding sodium oxide, or soda, Na_2O , 62, which, united to water, produces the hydroxide or caustic soda, NaOH , 40, and this forms soap, commonly hard, with the various fats.

All soils contain compounds of the metal sodium which have been derived from the disintegration of silicates or that have been carried down in the rains. The amount varies considerably in different soils and situations. Dr. Fream* gives that of a loam soil from Kent (a Hop soil near Sittingbourne) at 0.01, of a sandy soil from Staffordshire (near Rugeley), and a clay soil from Cambridgeshire (near Cambridge) at 0.06, and of a chalk soil from Norfolk (near King's Lynn) at 0.11 per cent. The older analyses give much larger percentages of soda in the soil, and those of plants exhibit a striking coincidence in the greater amounts found in them formerly than at the present time. Some uncertainty exists as to the older data, and in the recent the sodium is apt to be under-estimated or overlooked when mixed with much potassium, while, on the other hand, sodium, if present to the extent of a per cent. or more, is very liable to be estimated too high.

Thus, analyses become stumbling-blocks over which cultivators trip in the application of scientific research to the needs of the field and garden, especially as regards sodium and potassium. Indeed, the commonly prevalent belief that the labours of the chemist in his laboratory when he makes an analysis of a given soil will supply absolute figures as to the fertility of that sample for general plant growth is delusive. Of course, it is contended that if a chemist can analyse a plant and find out what it removes from the soil, why not an analysis of the soil furnish all the information needed as to what fertilising constituents should be applied? This proposition would seem to afford an easy method of arriving at a definite conclusion as to the needs of a soil and its adaptability to a given plant or crop. The idea that the requirements of the soil in the way of plant foods as ascertained by an analysis of it and the plant to be grown is simplicity itself, but there are modifying factors to be considered.

Plant foods may be—1, soluble in water—ready for use by plants; 2, soluble in very weak acids—this and 1 is called the available plant food; and 3, insoluble either in water or weak acids, and of no use to plants until changed into an available form. The chemist can separate these forms with considerable accuracy when analysing a fertiliser, and is able to compare the commercial value from the results secured. In the case of soils the chemist can tell—1, the total amount of plant food present; 2, how much is soluble of it with water; but, 3, cannot decide how much plant food is ready for use and how much is not. The discriminating power of the rootlets of plants are beside the chemist's

* "Elements of Agriculture," pages 20 and 21.

calculations, yet much in this direction has been ascertained by Prof. Bernard Dyer ("On the Analytical Determination of Probably Available Mineral Plant Food in Soils." Messrs. Harrison & Sons, St. Martin's Lane, London.)

A soil analysis, therefore, is not, as at first sight appears, a definite determination of the needs of that sample for chemical fertilisers. When analysed some soils are shown to contain enough plant food for many crops, yet the yield on such soils has been doubled by the supplying of a few pounds per rod or cwts. per acre of chemicals. Thus, though the total quantity of plant food present was large, the amount of available

available elements in the soil, for the increase is greater than could have been caused by the added chemicals alone. The impression is that chemicals act as stimulants, but the term is inapplicable to plants, for nitrates, sulphates and phosphates supply food; hence it is a matter of feeding, and a substantial dietary of nitrogen, phosphoric acid and potash, with proper conditions of heat and moisture, enable plants to make extra growth and cause them to make use of otherwise unavailable plant food in the soil.

There is another side to this question—that of the action of chemicals on the soil constituents and on the plant. As regards sodium or soda,

FIG. 75—LYCASTE SKINNERI.

nutriment was shown to be practically small. If the soil be deficient in any one element an analysis will show it; but when it indicates an abundance of plant food there is still question as to its available fertility.

Turfy loam, with additions of horse droppings, decayed manure, or leaf soil, even heavily manured fields or gardens, will show, on analysis, enough plant food to grow a prodigious crop, yet the tardy growth of plants in such soils demonstrates that but a small proportion is available; while, on the other hand, if a small amount of readily available plant food is supplied it enables the plants to make use of some of the partially

to which we will now confine our remarks, we have it both in the soil and plant as nitrate, sulphate, chloride, and carbonate. These are all commercial substances, and owe their value, from a chemist's point of view, for manurial purposes to the element with which the sodium is combined. Nitrate of soda is, therefore, the most important from this standpoint as supplying nitrogen to the plant. What is the soda to the soil? Does it accumulate therein to the prejudice of crops from consecutive applications? and, if so, what is the substance to apply to afford the needful relief? Here we have the sodium of the chemist, which is not a plant food. But the chemist is prepared for contingencies, and in cases of prejudicial soil alkalinity from abuse of nitrate of soda

corrects it by applying a dressing of sulphate of lime, CaSO_4 , 136, and thus converts the sodium from positive poison into absolutely beneficial sulphate. This is as far as we need carry this matter for practical purposes, and goes to show that sodium is, like other minerals, useful or otherwise according to its availability as food. But is it a food of plants or a needful element of soils for preparing matter, which, absorbed by plants and utilised in the building up of their structures, serves useful purpose?

Sodium carbonate, or carbonate of soda, Na_2CO_3 , 106, is usually present in the ashes of plants. According to Prof. E. von Wolff, the ash and soda in 1000 parts of the following substances consist of the subjoined average quantities, the first figures representing the ash and the second the soda:—Orchard grass 17.8, 0.8; Red Clover in flower 13.7, 0.3; White Clover in flower 14.3, 1.0; Beets 9.1, 1.5; Carrots 8.2, 1.7; Turnips 6.4, 0.6; Radish 4.9, 1.0; Parsnips 10.0, 0.2; Onion 7.4, 0.2; Jerusalem Artichoke 9.8, 1.0; Potato 9.5, 0.3; Cabbage, outer leaves, 15.6, 1.5; Cabbage, heart, 9.6, 0.8; Cauliflower, heart, 8.0, 0.5; Cucumber, fruit, 5.8, 0.6; Lettuce 8.1, 0.8; Asparagus, sprouts, 5.0, 0.9; Spinach 16.0, 5.7; Mushrooms 10.0, 0.2; Pea seed 23.4, 0.2; Pea straw 43.1, 1.8; Bean (horse) seed 31.0, 0.3; Kidney Bean seed 27.4, 0.4; fruit—Apple 2.2, 0.6; Pear 3.3, 0.3; Cherry 3.9, 0.1; and Grape 8.8, 0.1.

The amount of soda is a variable ingredient of plants, as shown by the proportions in the ash, and, as a rule, the richer the plant is in nitrogen the smaller the amount of soda; but however minute the quantity it is always present in each cell of every plant, and exists partly in the cell-wall, incrusting or embedded in the cellulose, and partly in the plasma or contents of the cell. It is soluble in water, and occurs in the juice or sap. This is true, in general, of the alkali metals, and of the sulphates and chlorides of calcium and magnesium. Silica, the calcium phosphates, and the magnesian compounds are mostly insoluble, and exist in the tissue of the plant in solid form, but these minerals enter the plant in liquid form, and in the matter of liquidation soda plays no insignificant part, especially in the case of silica, which, with lime and magnesia, present the most invulnerable wall to invading fungi. This at least is one reason for the use of soda as a manure.

Carbonate of soda is obtained from common salt by somewhat complicated processes, and is sent into commerce as soda ash, about a quarter of a million tons being annually prepared in this country for use in the industrial arts. It is an impure carbonate, but possibly of equal value for applying to land as washing soda—the sal-soda of America—which is the substance deposited when a solution of soda ash is allowed to crystallise, the crystals containing 63 per cent. of water, which partly escapes when the soda is exposed to the air, leaving a white opaque powder. Washing soda has the formula $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$, and is coming into use as a manure for Brassicas to induce sturdy and hardy growth, such as will insure more of the useful part with resistance of climate vicissitudes and of fungi and insects. Remember this has come from practice and not from science.—G. ABBEY.

(To be concluded.)

TULIPS.

BITTERLY cold east wind was blowing almost fiercely over the bulb ground at Long Ditton, where Messrs. Barr & Sons have such a wonderful collection of everything floral that is hardy. When I looked over them recently it seemed difficult to realise that under such adverse weather conditions beautiful flowers could be found in such profusion; but there were big clumps or masses of early Tulips in most glorious colour and profusion, such colouring, indeed, as would if found on any lawn have made it too garish to look upon, but distributed here and there, amidst bigger masses of now fading Daffodils and unbloomed Irises, seemed to be so acceptable and so lovely. Large as then was the show of early Tulips, I am not sure whether the display of late ones will not be greater.

In any case the collection of these latter at Long Ditton is an immense one, and will well repay a visit to the grounds in a very few days. A little genial weather, warm nights, and bright days should open the flowers rapidly. But whilst these latter Tulips bear close individual inspection, for the markings of the flowers are most beautiful as well as picturesque, the early Tulips are best suited to form brilliant masses, and as the bulk of them have self colours, so does one good flower represent the many. There are not a few beautiful parti-coloured flowers also, but without doubt those which most forcibly catch the eye are of self colours of the entire Tulip family; from the time the early Van Thols come into bloom until the latest fade away there is consecutiveness.

But where it is desired to obtain a fine show at one particular time no doubt those varieties which bloom concurrently are best. Out of the many of the early section I noted as the very best and most effective, as well as fine of flower, were the old white Pottebakker, large and rotund; Princess Marianne, white, flushed rose, the petals long and pointed; Chrysolora and Ophir d'Or, two splendid yellows; scarlet Pottebakker, very brilliant, with orange base, and rather deeper; La Belle Alliance, a very rich, effective Tulip; Proserpine, so well known, is a striking rosy magenta, and still deeper in colour and rather dwarfer is Adeline. A rich crimson colour is found in Dusart, and still richer is the superb red maroon Van der Neer, whilst darker still is Wouwerman. Rather taller and just a day or two later is the striking orange red

Prince of Austria; and finally of the selfs is Couleur Cardinal, rich scarlet purple.

These comprise in my estimation the finest of the self flowers. Some very beautiful bicoloured varieties, however, are charming, and especially so when closely inspected. The famous scarlet and yellow Keizers Kroon is universally grown. Fabiola, striped white and red; Rosamundi, red and white; cerise Gris de Lin, having a broad edging of white; and Cottage Maid are of the best of this section. I have here given a list of eighteen varieties, all of which may be obtained where there is room to plant and variety is desired. The doubles have their admirers, but I am not of them. I rather regard the double Tulip as a very lumpy, ungainly flower. Most certainly the singles are more pleasing in form, and because of the bold breadth of petal presented much the most beautiful. If the doubles want praise they must seek elsewhere for it than from me.

When the late varieties are open few doubles will be in evidence, and, whilst the markings and colourings of the flowers will compel admiration, no lover of the beautiful in floral form will be annoyed by the presence of lumps of petals that are obnoxious. It need hardly be said that apart from bulbs there are myriads of beautiful things in the Long Ditton grounds in the spring to attract attention. Aubrietias in huge clumps on rockwork are particularly effective; indeed, in all directions can be seen something to attract notice. I was much interested in the effective silvery variegation of the *Symphytum Bohemicum*, so useful in spring gardening with the marbled-leaved clumps of *Heuchera Richardsoni*, the Spotted *Pulmonaria*, and similar things, because in an unostentatious way they can be made to play a most useful part in winter and spring bedding.—A. D.

CONFUSION IN CONIFERS.

CUPRESSUS LAWSONIANA AND C. NOOTKATENSIS.

THAT there is a great exterior resemblance between these two species cannot be denied, and in consequence *C. nootkatensis* frequently does duty for *C. lawsoniana*. However much this is for several reasons to be regretted, I have from personal observation found that the mixing up of the two species is of very common occurrence. The differences are, however, markedly characteristic, for if the strong pungent smell of the foliage of *C. nootkatensis* were not sufficient, even in the dark, the more pendulous branches, larger cones with distinctly reflexed scale protuberances, and sulphury yellow catkins should render recognition by no means difficult. It may be well to add that the cones of *C. lawsoniana* are almost smooth, or only with a film-like appendage, and the pollen catkins bright red.

The cones of *C. nootkatensis* have four scales and eleven seeds, those of *C. lawsoniana* seven scales and nineteen seeds; while of the former 112,000 go to the pound weight, as against 105,000 of the other.

Unfortunately, for its value as a forest tree, the stem of *C. nootkatensis* is invariably carrot-shaped—thick at the base with a rapid taper upwards—and this is noticeable everywhere throughout the country.

THUJA ORIENTALIS FALCATA.

The various varieties of the Chinese Arbor Vitæ are in a sad state of confusion—indeed, many are incapable of accurate identification. I have seen three totally distinct forms of the so-called *T. orientalis falcata*, and as these are growing in the same grounds, and not 50 yards apart, and under similar conditions in every way, the chances of mistaken identification in this particular instance are very remote.

The first or normal form is of larger growth than any of the others, of upright but not appressed growth, and with large deep green cones that are twice the size of the species. Second comes a much smaller growing perfectly taper-like shrub, the foliage of a different shade of green, and the cones similar in every respect to the latter; and third, the most distinct and ornamental of any—a neat-habited shrub with yellowish green foliage, that is quite uniform in colour all over the specimen, and with unusually large cones, many of these, being fully an inch long, the sickle-shaped spines being very conspicuous.

So long are the spines in this particular form that they might well be likened to a molar tooth with the fangs intact. This is most noticeable when the cones have attained to full size, but before becoming ripe, for at the latter stage the shrinkage of the spines is very perceptible. This golden form is well worth cultivating, the neat habit and bright tint of both foliage and bark rendering it a very desirable garden shrub.—A. D. WEBSTER, *Boarwood, Herts.*

ANIMALS POISONED BY BROOM.—All parts of the Broom—root, stem, leaf, and flower—are more or less poisonous to animals, owing to their containing two alkaloids, scoparine and sparteine, the latter especially being dangerous. In any case the Broom is not only purgative, but is also very emetic in its effects. The horse and the ass detect more readily than the ruminant animal the sickly odour and the bitter taste of the plant, and are less likely to eat it. But should a horse, ass, or mule have eaten Broom in any more or less considerable quantity, there should be no delay in administering the antidote, which is found in a large dose of coffee, 7 or 8 quarts or so, given warm and weak. The effect of this remedy, says the "Revue Horticole," is not always certain, and it is best to prevent the animals from browsing on Broom, whether it be *Genista scoparia*, *G. juncea*, *G. tinctoria*, or any other species.

THE ONION FLY (PHORBIA CEPETORUM), MEADE.

THE Onion fly causes serious injuries to the Onion crop in some seasons, and it appears to be on the increase in this country. It is also a source of great trouble to the Onion growers in the United States, and in continental countries. Frequently in English market gardens and market garden farms, where Onions are extensively cultivated, large percentages of the plants are quite spoiled by the attacks of this fly. In cottage gardens and allotments the whole of the plants on the small Onion beds of the cultivators are often ruined by successive generations of this insect.

The first indications of the infestation are shown by the longest or first leaves of the Onion plants becoming yellow, and afterwards whitish; if these are pulled they come easily away from the stem, and gradually the other leaves become yellow and decay. The bulb will be found to be small and badly shaped, and having yellowish maggots within its folds, feeding upon it, and eventually causing it to become rotten and useless.

In other cases, the outer or lower leaves of the plants are seen to be lying on the ground, still green, while the leaves remaining upright and green feel soft and flabby.

If infested plants are examined it will be generally noticed that in the case of very young plants they are nearly eaten through, just above the swelling bulbs, by the maggots or larvæ of the fly. In older plants, with large bulbs, maggots of all ages and sizes will be found within the bulbs.

Onion plants that become yellow and show signs of drooping should be examined for maggots just below the surface of the ground.

LIFE HISTORY.

The male and female flies of this species differ slightly. The male is dark grey in colour, with black bristles. The eyes are red and close together. Upon the thorax are four bright brown stripes and four rows of black bristles. The abdomen is ash-coloured, rather narrow, having triangular black spots down it which almost join each other. The legs are pithy.

In colour the female fly closely resembles the male, but the abdomen is dark grey, with the end more pointed than in the male; and the eyes are wide apart.

From six to eight eggs are laid on an Onion plant, upon the leaves and just above the ground. The eggs, which are white, long, and somewhat oval, can be easily seen without a glass. Maggots (larvæ) come from the eggs in from five to seven days, according to the temperature and other conditions, and make burrows down into the root, or bulb, between the sheathing leaves. They feed upon the contents of the cylindrical root which can hardly at this stage be styled a bulb, and move on to other plants. Later on, when the bulbs are larger, they are occupied by many maggots, which feed on them and cause them to become rotten. Sometimes the bulbs will be seen to be swarming with maggots, and the earth round them is also infested. The maggot continues in the larval state for a period varying from thirteen to fifteen days, feeding throughout this period upon the Onion roots or bulbs. It is nearly four lines (one-third of an inch) in length, dull yellowish white, or dirty white, in colour. The head part of its body is sharply pointed, and the head, furnished with a pair of black hooks, can be extended at will; the tail end is cut off obliquely flat, and in the centre there are two brown spiracles or breathing tubes, and on the margin of the flat tail end there are eight teeth or projections.

Before pupation takes place the maggot usually goes into the earth. Sometimes pupation occurs within the Onions. The pupa, or rather the pupa case or puparium, is chestnut brown, oval, not so long as the maggot, and has the same toothlike projections on the caudal end. On opening this puparium the white pupa will be seen with the embryonic wings of the future fly, which appears in from thirteen to sixteen days after pupation.

There are several generations of this insect. The first has been seen as early as the 25th of April in very forward seasons, and flies have been noticed through the autumn and as late as November. Curtis states, however, that he saw them alive in December.

METHODS OF PREVENTION AND REMEDIES.

Spraying Onion plants with offensive compositions is a good way of preventing infestation. Paraffin emulsion is as good a compound as any for this purpose. It may be made by thoroughly mixing together 3 pints of paraffin and $\frac{1}{2}$ lb. of softsoap with 1 gallon of boiling water. Mixing may be done by passing the composition through a hand pump once or twice; 6 gallons of water should be added to dilute it sufficiently, so as not to burn the Onion leaves. When the Onion leaves are young and very tender 7 or 8 gallons should be added. It may be applied on small plots of Onions with a Knapsack machine; on large breadths with a horse distributing machine. The spray should be dense and in the form of mist. This operation should be performed early in the season, when the Onions have established their leaves.

Spraying must be repeated, probably twice or thrice, especially if heavy showers fall after the process.

When Onion plants in a field or garden are noticed to droop and wither all such plants should be taken up and burnt or deeply buried. They must be taken up by means of a little three-pronged fork, or some other handy tool, so that every particle of bulb and leaf is removed.

Wherever it is possible Onions should not be grown again for at least one season on land where this crop has been infested, as the pupæ

remain in the ground during the winter. All pieces of bulbs should be got off infested land, as pupæ occasionally remain in the bulbs. If it is necessary to take two successive crops of Onions on infested land the ground should be dug very deeply, two spits deep, and well limed or gas-limed.

Sprinkling the young Onions with soot has been adopted with some advantage; but the pungent odour soon evaporates, and it is necessary to give several dressings.

Kainit, broadcasted on land cropped with Onions at the rate of 5 cwt. per acre, has been found to be of great use. The action of kainit as a preventive of some kinds of insect attack in larval form has been often noticed, though it is rather difficult to define the form or nature of its action. In the case of the Onion maggots it would appear that kainit prevents their progress from one Onion to another, either by the shape of its crystals or by some pungent emanation from it. It is not the stimulus that it gives to plants which make them grow away from their enemies, as kainit is not by any means a forcing manure. Kainit should be hoed very lightly in after it has been broadcasted on.

Nitrate of soda, applied at the rate of $1\frac{1}{2}$ to 2 cwt. per acre, should be

FIG. 76.—a and b, Larva, natural size and magnified; c and d, Pupa, natural size and magnified; e, Fly magnified; lines showing wing expanse and length of body.

put on infested land in order to stimulate the plants and make them grow away from the enemy.

Lime and soot, mixed together in the proportion of 1 bushel of soot to 2 bushels of lime, very finely powdered and broadcasted over the infested plants, and lightly hoed in, has been efficacious in a degree.—(Board of Agriculture Leaflet, No. 31.)

EVOLUTIONARY ESSAYS.

EVOLUTION was once a terrible word to many, and amongst these some of the ablest and best of men who gave thought, all of them perhaps not the most profound, to the subject. Not a few of these, however, in time came to regard evolution as not such an outrageous thesis after all, but as something associated with one of the first laws of Nature—growth, or in other words steady advancement, gradual, imperceptible progress, like the growth of a tree from its seed, but culminating in a change not less marvellous than tangible and indisputable. Let no one, then, be frightened by the once dread word of evolution, because in reality its significance is apparent everywhere in the animal, vegetable, and mineral kingdom.

In "Evolutionary Essays" we merely condense the sub-title, indicating the nature of an American work, of which the chief and formal title is the "Survival of the Unlike," a sort of parody, we may almost venture to say, on another formula not unfamiliar—namely, the "Survival of the Fittest."

The author of this work—which we have had in hand for a considerable time, but which, owing to pressure on space, could not be sooner referred to—is Mr. L. H. Bailey of the Cornell University, Ithaca, New York.* We venture to say that no one knows better than the author of this volume of over 500 pages that the title he has chosen embodies a mere truism. No one knows better than he that variety, or exact unlikeness, meets us everywhere. No two individuals can be said with accuracy to be precisely alike in respect to appearance, habits, and influences; no two men, animals, plants, trees, leaves, or flowers can be said to be absolutely identical. There are divergencies more or less apparent, but all the same existent, though in some instances the microscope may be necessary to reveal them. This being so, it may be conceded that Mr. Bailey has chosen his title wisely, because under it may be written essays on almost every conceivable subject connected with animal and plant life; but it is not everyone to whom it is given to write so lucidly, and it may be said so logically, as the author of this volume before us. The work comprises, as is stated on the title page, a "Collection of Evolutionary Essays Suggested by a Study of Domestic Plants." It seems to be composed of some thirty lectures delivered at more or less wide intervals, and though there is something of interest in most of them it can scarcely be said that complete harmony pervades the whole; indeed, it is hard to exercise the suspicion that an obviously able man could not wholly resist on all occasions the temptation of what is known on "this side" in homely vernacular as padding; yet let it be said that the handbook as a whole is well worth reading.

We have no particular inclination to criticise, adversely or otherwise, the theories of the author or his methods of treating the multitudinous

* The Macmillan Company, Bedford Street, Covent Garden, London.

subjects which he brings under review; and besides, the nature of the work will be more fairly represented by a few citations, with or without a few words of comment as the matter may or may not suggest. One thing may be said—namely, that the author goes as far as he can to the beginning of things, and endeavours to follow them to the end as guided by his own intellectual light or the light of others that may have illumined his path. Commencing with the nature and divergence of the plant and the animal, the author says:—

"It is self-evident that the development of life upon our planet has taken place along two divergent lines. These lines evidently originated at a common point. The common life-plasma was probably at first more animal-like than plant-like. The stage in which this life-plasma first began to assume plant-like functions is closely and possibly exactly preserved to us in that great class of organisms which are known as mycetozoa when studied by zoologists, and as myxomycetes when studied by botanists. At one stage of their existence these organisms are amoeba-like—that is, animal-like, but at another stage they are sporiferous, or plant-like. The initial divergencies in organisms were no doubt concerned chiefly in the methods of appropriating food, the animal-like organisms apprehending their food at a more or less definite point, and the plant-like organisms absorbing food throughout the greater or even the entire part of their periphery. . . . If we turn to plants, we find the rotate or peripheral arrangement of parts emphasised in all the higher ranges of forms. The most marked bilateralism in the plant world is amongst the bacteria, desmids, and the like, in which locomotion is markedly developed; and these are also amongst the lowest plant types. But plants soon become attached to the earth, or, as Cope terms them, they are 'earth parasites.' They therefore found it to their advantage to reach out in every direction from their support in search of food. Whilst the centrifugal arrangement has strongly tended to disappear in the animal creation, it has tended with equal strength to persist and to augment itself in the plant creation. . . . The vegetable world does not exhibit, as a whole, any backward step, any loss of character once gained, nor any stationary or retarded periods." Is that so?

Then Mr. Bailey goes on to say, and not many persons will presumably controvert his opinion, that—"This phrase—the survival of the unlike—expresses no new truth, but I hope that it may present the whole truth of vicarious or non-designed evolution in a new light. It defines the fittest to be the unlike. . . . I am so fully convinced that, in the plant creation, a new character is useful to the species because it is unlike its kin, that the study of differences between individuals has come to be, for me, the one absorbing and controlling thought in the contemplation of the progress of life. These differences arise as a result of every impinging force—soil, weather, climate, food, training, conflict with fellows, the strain and stress of wind and wave, and insect visitors—as a complex resultant of many antecedent external forces, the effects of crossing, and also as the result of the accumulated force of mere growth; they are indefinite, non-designed, an expression of all the various influences to which the passive vegetable organism is or has been exposed. . . . Thereby there is a constant tendency for new and divergent lines to strike off, and these lines, as they become accented, develop into what we, for convenience sake, have called species. There are, therefore, as many species as there are unlike conditions in physical and environmental nature, and in proportion as the conditions are unlike and local are the species well defined. But to Nature, perfect adaptation is the end; she knows nothing, *per se*, as species or as fixed types. Species were created by John Ray, not by the Lord; they were named by Linnaeus, not by Adam."

Most persons will agree with the following observations:—"A good gardener is one who grows good plants, and good plants are very unlike poor plants. They are unlike because the gardener's love for them has made them so. The plants were all alike in November; in January the good gardener's plants are strong and clean, with large, dense leaves, a thick stem, and an abundance of perfect flowers. The poor gardener's plants are small and mean, with curled leaves, a thin, hard stem, and a few imperfect flowers. You will not believe now that the two lots were all from the same seed pod three months ago. The good gardener likes to save his own seeds, or to make his own cuttings; and next year his plants will be still more unlike his neighbour's. The neighbour tries this seed and that, reads this bulletin and that, but all avails nothing, simply because he does not grow good plants. He does not care for them tenderly, as a fond mother cares for a child. The good gardener knows that the temperature of the water and the air, the currents in the atmosphere, the texture of the soil, and all the little amenities and comforts which plants so much enjoy, are just the factors which make his plants successful; and a good crop of anything, whether Wheat or Beans or Apples, is simply a variation. And do these unlikenesses survive? Yes, verily! . . . The cultivated flora has come up with man, and if it has departed immensely from its wild prototypes, so has man. The greater part of all this has been unconscious and unintended on man's part, but it is none the less real."

The author has much to say on bud variations and sports, indeed the chapter in which the subject is discussed is perhaps one of the most interesting in the book. A few citations will best display its character. "Bud variations," or those 'sports' which now and then appear on certain limbs or parts of plants, are nearly always readily propagated by cuttings. These variations cannot be attributed to sex, in the ordinary

and legitimate application of the Weismannian hypothesis. Whilst these 'sports' are well known to horticulturists they are generally considered to be rare, but nothing can be farther from the truth. As a matter of fact, every branch of a tree is different from every other branch, and when the difference is sufficient to attract attention, or to have commercial value, it is propagated and called a 'sport.' . . . In other words, plants multiply both with and without sex. Potentially, every node and internode of the plant is an individual, for it possesses the power, when removed and properly cared for, of expanding into what we call a plant, and of perfecting flowers and seeds, and of multiplying its kind. . . . The nurseryman knows that branches differ amongst themselves, for he instructs his budders to cut buds only from the topmost shoots of the nursery rows, in order that he may grow straight, vigorous trees; and every farmer's boy is told that he should never select scions from the centre or lower part of a tree. Every skilful horticulturist will tell you that the character of the orchard is determined very largely by the judgment of the propagator in selecting scions." And it is further intimated that scions taken from vigorous young trees which have not fruited (as in nursery rows) may be expected to give trees which will be later in bearing than others which have been propagated from fruiting trees.

The influence of climate as changing the shapes of Apples is specifically noted. "The similarity of the same varieties of Apples grown in the Eastern and Western States" being said to "end with their names," for "the Apples themselves are very unlike. They have been modified by climate until they are larger, longer, and more conical, frequently marked by prominent ridges at the apex, less firm in flesh, and often somewhat inferior in quality. To all intents and purposes many of them are distinct varieties from their parents in the East, and they afford as distinct and unequivocal cases of evolutionary modification as the most hypercritical can wish to see. The Newtown Pippin affords one of the best instances of rapid modification of any American fruit. It has always been a local and capacious Apple in New York State, where it originated, yet in the Piedmont region of Virginia it is the leading Apple, known as the Albemarle Pippin; in the far North-west it is again the leading Apple over a great territory, and in New South Wales, under the name of Five-Crowned Pippin, it is still again a dominant variety. Yet in each of these four geographical regions the variety attains a specific character which it does not possess in the others."

The question of dessert Apples receives prominent attention. In America Apples are graded on a decimal scale in three distinct categories—dessert, cooking, and market. Each variety is also rated, in size and colour. The standard of excellence, as determined by a great fruitist, Mr. Lyon, is high, and only the very choicest varieties reach figures 9 and 10. Long lists are given of these and other fruits, their relative values being represented in figures, with 10 as a maximum. The result is that "we find thirty-eight varieties of Apples graded 9 and 10 for dessert, of which only three are rated small, while seven are large, and two are very large. Those rated as medium to small are two, and those medium to large are three. Of these thirty-eight entries, therefore, six, or less than one-sixth, would be called small Apples, and thirteen, or over one-third, are large Apples, the remaining ones being classed as medium or intermediate." The author goes on to say, "It is evident, from our discussion, that quality and other characters of cultivated fruits appear independently of each other—that there is no true correlation between these characters. There is a general increase in all characters as amelioration progresses, at least in all characters which are sought by horticulturists; and this fact must ever remain the chief inspiration to man in his efforts to ameliorate plants."

There is much more in the book worthy of attention, though no doubt some chaff amongst the grain; still, the "Survival of the Unlike" is entertaining, instructive, and suggestive. It is a readable hook, which is no small merit, and as a "handbook" it is the lightest in weight of any we have handled that is composed of nearly 500 pages. The price is not stated, but we do not suppose it is prohibitive to the great bulk of gardeners and amateurs in the Old Country, in which there are happily a few "dollars" left; we should like to know there are many, as the reward for honest labour in the domain of horticulture.

FEEDING ROSES.—Mr. Robert Simpson, writing to "The American Florist," says that it is a mistake to feed Roses under glass or other plants of this class abundantly in autumn or early winter, while the plants are small and soft and while the soil is still rich in plant food, with comparatively few roots to use it. But in the spring, when the soil is full of roots, the sun powerful and the growth rapid, unless nutriment is furnished just as fast as it can be consumed by the plants, small shoots and smaller flowers will be the result. Of course, we cannot take fresh manure from the stable into the greenhouse and use it as a mulch. It should have been heaped up last summer, turned over once or twice in the autumn, and stored before cold weather in a shed or other dry place where it can be reached and handled at any time. In this season of growth the surface of the benches should be sprinkled over with a dusting of finely ground bone or wood ashes, or, better still, with a mixture of both, and this should be covered with a mulch an inch thick of the well-decayed manure and soil mixed in equal quantities. Liquid manure may be omitted for a week after the mulch is spread, otherwise it should be attended to faithfully and regularly, giving it frequently in a very diluted form.

HIBBERTIA PERFOLIATA.

THIS interesting plant is now flowering in most gardens where it is grown, although unfortunately there are exceptions to the rule, inasmuch as *Hibbertia perfoliata* (fig. 77) is not generally cultivated. The *Hypericum*-like flowers are bright yellow, and being freely produced render the plant very attractive. Several species of *Hibbertias* are grown in conservatories, usually trained to pillars or the roof, but *H. perfoliata* is more compact in habit, and, like the smaller-flowered *H. Reedi*, is better suited for culture in pots. The flowers are not of long duration, but so many are produced, and in such close succession, that the plant continues ornamental for a considerable time.

APRIL CHARACTERISTICS.

THE end of April is peculiarly the period of Nature's "smiles and tears." Of late the latter have greatly predominated, and occasionally they were of an exacting description; heavy showers, mingled with hail, and sometimes with snow. It was a dangerous time for blossoming trees, many of which, notwithstanding the recent visitations of frost, are already in flower. Among these, in my own garden, is the beautifully foliaged *Prunus Pissardi*, the blossoms of which form a striking contrast to the crimson-purple leaves. This is, assuredly, one of the most highly ornamental of Eastern trees.

The Early Rivers Plum and the prolific *Victoria* are the earliest in bloom; among contemporaneous Cherries are *Black Eagle*, *May Duke*, and *Werder's Early Black*. Only a few days have intervened between the blossoming period of any of these. The Pear trees are usually considerably later, but several varieties, such as *Pitmaston Duchess*, *Early Crawford*, *Rivers' Fertility*, and *Doyenné du Comice* (which Mr. Rivers once assured me was the finest Pear in cultivation) are already preparing to burst into bloom. In the South of England they are considerably earlier; which, considering the weather we have recently experienced, is a fact their cultivators may have reason to deplore.

Very picturesque at present are the blossoms of the rosy tinted Almond and those of the double flowering Peach, both of which trees are highly ornamental. Ere long the Apple trees will be in full beauty, and there is every prospect of abundant bloom. Irish Peach is already exhibiting its roseate buds, and such varieties as *Duchess of Oldenburg*, *Stirling Castle*, *Lady Sudeley*, and *Beauty of Bath* (a great acquisition) are already far advanced. But the blossom of the Apple is only embryonic in April; it is the precious possession and crowning glory of May. Its most fascinating contemporary is the flower of the Hawthorn, which is yet in its infancy, though plainly discernible amid the enfolding and protecting leaves. By many a wayside in this beautiful sea-girt parish, and in many a shadowy glen the snow white blossom of the Blackthorn presents a picture which only can be witnessed at this season of the year.

One of the most charming of April flowers is the *Auricula*. Though I have not made it a special study like Mr. Harry Turner or the Rev. H. H. D'Ombrian, I can understand their admiration for this vernal gem. Lily of the Valley is developing very rapidly now that the rains have become softer and more congenial, and ere long its intensely fragrant flowers will be found nestling in all their gentle loveliness among its luminous leaves.

Roses at present have such brilliant foliage that no lover of Nature can fail to admire their varied hues. Especially radiant are such varieties as *Madame Pierre Cochet*, *Margaret Dickson*, *Mrs. W. J. Grant*, *Niphetos*, *Homère*, and *Perle des Jardins*; very graceful are also the *Austrian*, *Persian*, and *Penzance Briars*, which are for the most part of a pendulous habit, and have a strong fascination in the fragrance of their leaves. Lilies have of late been growing with marvellous rapidity. Many of my candidums, auratums, excelsums, davuricums, and Martagons; also *Lilium Humboldti*, the *Caucasian Szovitzianum*, and the Chinese *Henryi* promise to bloom very early this year. On the other hand, the tender stems of *Lilium longiflorum Takesima* and *L. Harrisii* do not seem to appreciate such weather as we have experienced, and have suffered in many instances from atmospheric visitations. *Lilium Kramerii*, one of the most beautiful and distinctive of Lilies, is, fortunately for itself, only beginning to appear.

The *Narcissi* are at present in splendid bloom; the invincible *Horsefieldi*, which has immortalised the name of its humble originator; *N. Barri* conspicuus, a hybrid of great distinction; *N. ornatus*, *Orange Phoenix*, *Queen of Spain*, and *N. Tazetta*, of which Homer and Sophocles sang so impressively—combining their rich and varied beauties to form intensely artistic effects.—DAVID R. WILLIAMSON.

NARCISSUS TRIANDRUS ALBUS (ANGEL'S TEARS).—A London evening paper, in describing the Daffodils at Long Ditton, observes:—"There is a story attached to the name of the 'Angel's Tears.' Mr. Barr, senior, the 'Daffodil King,' on one of his rambles in Spain discovered the flower, and gave his lad orders to go and dig the bulbs up. The day was hot, and Angel (such was the youth's poetic name) shed copious tears at the idea of digging bulbs in the sun, whereupon Mr. Barr, on sending home the bulbs, alluded to them jestingly as 'Angel's tears,' and the name has adhered to the *Narcissus triandrus albus* from that day forth."

FRUIT PRESERVATION.

AN interesting experiment in the preservation of fruit by means of cold storage has been carried out during the past season by the Technical Education Committee of the Kent County Council at Dartford. The experiment has been personally superintended by two members of the Committee, Messrs. Hesketh and Chambers, whose reports are now issued. They state that the stores were kept at steady temperatures of 30° and 40° until near the end of the year, when it was considered there would be no further utility in prolonging the experiment under the same conditions.

Mr. Hesketh's report thus proceeds:—The fruit loses weight somewhat during the refrigerating process, as is evident by the amount of moisture collected off the brine walls, which amounts to 15 per cent. of the weight of the fruit per week. This moisture is absorbed from the fruits by the air during its natural circulation in the chamber, and

FIG. 77.—HIBBERTIA PERFOLIATA.

deposited on the colder surface of the brine walls from which it is drained away. The air is thus kept in a dry condition. An object in future experiments will be to reduce this desiccation of the fruit, but still maintain the dry condition of the air, which is so essential in avoiding mildew.

It is, of course, a matter of common knowledge that fruit, especially of the harder kinds, can be kept back for a time from ripening by means of refrigeration, such knowledge being taken advantage of for bringing fruit from Australia and the Cape to England; but one main object in this experiment was to show the cost of fruit preservation on a small scale, such as our fruit growers might find of service. A careful log has, therefore, been kept of the working expenses, and this shows that the total cost of engine power (gas at 3s. 6d. per 1000 cubic feet being used in a gas engine) and all stores amounted to 8s. 9d. per day. This does not include anything for labour, as only the occasional attention of a labourer otherwise employed is required. The cost of working by an oil engine would be approximately the same.

The refrigerating machine, which is the smallest size practicable, was capable of dealing with a much larger chamber, its average hours of working per day being only three and a half. If an average of twelve hours a day for the working of the machine is taken, it could then maintain a store 24 feet by 24 feet by 8 feet high, which would be capable of storing some 2000 bushels of Apples. The cost of working the machine on such a chamber, based on the experience gained in the recent experiment, would be 2s. 2d. per day. Of course, larger installations, worked with larger machines, would cost much less to work in proportion to the quantity of fruit kept. It is proposed to make experiments during the coming summer on the soft fruits as they come in season.

In that portion of the experimental work managed by Mr. Chambers 4½ bushels of fruit were stored in the chambers for 101 days, and 35½ bushels for fifty-six days. Mr. Chambers states that some of the summer Apples left in the store until the close of the experiment were found to be sound, but were not so good in flavour, and were somewhat soft. On the other hand the winter Apples were of as good flavour as when put in, and were quite as hard and sound.—("Times.")

THE YOUNG GARDENERS' DOMAIN.

THE CULTIVATION OF BOUVARDIAS.

THESE beautiful plants are grown from cuttings taken from the old plants, which after flowering have been slightly rested, cut back, and started again. A mixture of fibrous loam, leaf soil, and sand is suitable for the cuttings, of which five may be inserted in a 60-size pot, watered and plunged in a close frame where there is a bottom heat of about 75° to 80°. When the cuttings are rooted they should be placed singly in "thumbs," using the same compost as before, placing the young plants as near the glass as possible in a moist temperature ranging from 60° to 65°, and keeping them well syringed.

As soon as the roots take possession of the new soil the plants must be topped at the second joint, repeating the process until they attain the bushy habit desired. Before the small plants are root-bound transfer them to 48's, taking care to disturb the roots as little as possible in removing the old crocks. The compost may be the same as before, with a little peat and spent Mushroom bed material added, passing this through a half-inch sieve. When the new soil is fairly occupied with roots the plants may be arranged on ashes in a cool frame.

During hot sunny days they require to be shaded with tiffany, also kept well syringed, and afforded a free circulation of air. When the 5-inch pots are filled with roots weak liquid manure will be of great assistance to the plants. Red spider and green fly are very partial to Bouvardias, but if the plants are frequently syringed the former will not obtain a hold, and the latter is easily prevented by occasional fumigation.—ELVEDEN.

[If this young man learns to write as well as his father can work there will not be many to surpass him.]

DIPLADENIAS.

THESE are among the showiest of all stove-house plants. When well grown they are very beautiful objects, and whether in the exhibition tent or in the hothouse they are always attractive. To begin with, one must have a good command of heat, as they require a high temperature the whole year round. They are propagated by mossing a shoot or cuttings. By the former method the strongest plants are obtained. Select a strong young shoot about 2 feet in length, bind a little moss round a joint, and as soon as roots can be seen through the moss, which should be kept moist, get a pot split in halves—a 5 or 6-inch one is best—and fit it round the mossed joints; then fill with equal parts of sphagnum and lumps of peat with a little sand. As soon as the pot is full of roots the young plant may be severed from the parent and eventually repotted, shading it for a few days. Cuttings of most varieties emit roots if inserted in a mixture of peat and sand and placed in a propagating pit with a brisk bottom heat.

The best soil I have found for Dipladenias consists of equal parts of good peat and fibrous loam, in pieces about the size of walnuts, with charcoal and sand, adding a little artificial manure for large plants. If the loam is of a heavy nature some half-decayed leaf soil should be used and only half the quantity of loam. The pots should be well drained and the soil made very firm.

After potting the plants are best placed where they receive a little bottom heat, but this is not necessary if the watering is attended to by a careful man. When not growing very little water is needed; at no time do they require a large amount, and it must always be given with judgment. When the pots are filled with roots the plants can be assisted with a little weak tepid liquid manure made of soot and cow manure.

The training of Dipladenias is an important factor in their cultivation. The best method is by small strings connected with the roof of the house, as these can be cut away to clean the house or plants; in fact it is the best method for any climbing stove plant, the young shoots twisting around it far better than wires. As soon as the points of the shoots reach the top of the house a balloon-shaped trellis should be fitted on the pot, then carefully wind the shoots about twice round it, taking the upper part to the roof again.

If the plants are required for exhibition the flower spikes should be held upright by means of a few tints in the roof, and tied with raffia. Then a few days before the exhibition they can be put on the trellis, and

the flowers will be in an upright position. After the exhibition they can be taken off the trellis and trained to the roof again, when they will continue flowering much longer than if left on the trellis; in fact they can be had in flower for five months of the year, which is a great recommendation.

One of the reasons why Dipladenias are not more generally grown, is owing to their being subject to the attacks of various insects. Aphids attack the young shoots, and thrips the flowers, but these can be coped with successfully by smoking or vaporising. Their greatest enemies, however, are red spider and mealy bug. For preventing red spider there is nothing better than frequent spraying with soft water on fine days. Instead of the ordinary method of twice a day the plants may be syringed four or five times on hot days. A good prevention or cure for mealy bug is this—to every four gallons of hot soapy water add one wineglassful of petroleum, this, if used according to the directions below, will be found very effective against insect life. Choose a dull day, and clear out any plants there are underneath the Dipladenias, and while one man or boy mixes with a syringe, another can syringe on the plants, wetting all parts, afterwards syringing with clear water. If this is done about once a fortnight through the growing season little harm will be done by insects. Three of the best varieties of Dipladenias for all purposes are Brearleyana, amabilis, and boliviensis.—J. L. G.

["J. L. G." will be glad to know that if his large sheet of paper, on which the whole of this article was written had been cut into four parts, he would have added much to the convenience of the printers.]

CROTONS.

CROTONS are charming foliage plants, admired for their bright colours. They are grown in the form of specimens for exhibition, also for grouping, as well as, in a small state, for table decoration. For large specimens I do not think there are many to excel the varieties Queen Victoria, Warreni, Williamsi, Prince of Orange, Prince of Wales, Johannis, The Countess, Andreanus, and volutus. For table and graceful plants for grouping purposes, I think Chelsoni, angustifolius, Johannis, The Countess, Aigburthensis and Warreni are among the most suitable.

As regards to the cultivation of Crotons. They should have a well-heated house to themselves wherever it can be provided. The pipes should not be overheated, but a good temperature maintained. When the pipes are few in the houses, they have to be too highly heated for the well-being of the plants.

Crotons in their growing season, which is about eight months, require a temperature from 70° to 75° at night, rising to 85° or 90° during the day, with sun heat. During the winter months, 60° at night, rising 5° during the day, will suffice. Crotons should be frequently syringed to prevent the appearance of thrips and red spider, which, if allowed to increase, spoil the foliage and deprive the plants of beauty.

As regards soil, I have seen the following used with the best results: Good fibrous loam, adding one-third each of peat and coarse sand, with a small quantity of Thomson's or Clay's manure. The pots must be clean and well-drained. Crotons require copious supplies of water.—W.

[If this correspondent has kept a copy of his communication he will find how great is the necessity for more care in composition; he must also allow twice the space between the lines. It is a pity that such a good penman, and, we believe, plant grower, should not take more pains in the directions indicated.]

EUPHORBIA JACQUINIEFLORA.

THE Euphorbia is one of the most showy and useful of our winter-flowering plants, which deserves to be more widely cultivated in private establishments where there is a demand for cut flowers. It will stand the dry air of rooms remarkably well, and what is more beautiful for table decorating or for ladies' sprays?

All plants that have been resting should be placed in the stove at once, if not already there, giving them a thorough watering, also keeping them well syringed, when they will soon break. When the growths are from 3 to 4 inches long take them off with a little hard wood, and insert singly in "thumbs," or five cuttings round a 60-size pot. They strike well in a compost of equal parts loam, leaf mould, peat, and sand.

Place them in a propagating frame, with bottom heat of about 80°; shade from bright sun, and do not keep them too moist, or they will damp off. As soon as they are rooted give a little air during the day, and open the frame fully at night, which will prepare the plants to endure the air and sun of the plant stove. When they are well rooted pot singly in well-drained 60's. Stop the plants when they have grown about 6 inches. From three to four shoots will be sufficient for flowering, if long racemes of flowers are desired. Keep the plants close to the glass in the plant stove or intermediate house. When they have filled their pots with roots, and before they are root-bound, transfer them to 54's, using an extra part of loam to the above-named compost. Watering must be carefully attended to at all times.

The plants may be further shifted into 32's—a suitable size to flower them in. See that they are properly crooked, using a compost of two parts loam to one part each of leaf mould, peat, and spent Mushroom bed refuse, with a dash of sand; stand the plants on a moist cool base, and keep the syringe playing freely amongst them. As soon as they begin to form their flowers is the time to commence feeding, liquid manure being preferable to top-dressing. When the flowers are half expanded the plants should be removed to a drier house, say a warm conservatory, as they are liable to damp off in a moist atmosphere. Old plants may be planted against the back wall of a lean-to house, where

they will afford many useful sprays for cutting. It is far better to grow a few plants well than to attempt to grow many more than there is room for, or than can be properly attended to.—GROWER.

[Our correspondent desires to know if he is trespassing on our space. Our reply is, "No." He can, if he take pains with his pen, occupy a portion of it usefully.]

FRUIT FORCING.

Cherry House.—Where the trees were started at the new year and have been brought forward steadily the fruit will have stoned and commenced colouring, and be swelling rapidly for ripening. The temperature may now be raised, but it must not exceed 65° by artificial means and 55° to 60° at night, with a little ventilation, increasing it at 70°. Subject to the leaving of a little air on constantly at the top of the house close at 70°, but the temperature must not be allowed to exceed that degree in the early part of the day without full ventilation. From the commencement of colouring until the trees are cleared of their fruits syringing must cease, or the fruits will crack, but humidity should be maintained in the house by keeping the surface of the border moistened as it becomes dry, or if the trees are in pots—a very desirable method of growing this very acceptable fruit—damping the floor two or three times a day, avoiding, however, a stagnant atmosphere. Aphides, which are apt to settle on the points of the young shoots, must be kept under by vapourisation with nicotine essence, or fumigation with good tobacco paper or rag, as it does not answer to apply an insecticide in powder or liquid form after the fruit commences ripening. The border must not lack moisture, and trees in pots must be properly attended to as required in watering. Place some netting over the ventilators to prevent birds attacking the Cherries. Stop the extending growths of trees in pots at the fifth leaf, and laterals to one joint as made. Trellis-trained trees should have the shoots tied in as they lengthen, and those not required for training in may be stopped at about the fifth leaf.

Cucumbers.—Plants in bearing all the winter will now be showing signs of exhaustion, and would be best removed, cleansing the house, providing fresh soil, and putting out fresh plants without delay. This is far better than renovating old plants, and there is no very material break if care is taken to have strong plants ready for placing out, which come into bearing within a few weeks; indeed, some turn out large plants, and by cropping lightly have no break in the succession, as Cucumbers cut young will keep plump and fresh several days with their heels in saucers of water. Young plants coming into bearing will be the better for removing the male flowers and most of the first fruits, stopping at two or three joints beyond the fruit, removing all weakly and unnecessary growths. Encourage a free root action by adding fresh warmed soil to the hillocks or ridges as the roots protrude, sprinkling a little fertiliser on the newly added soil, such as superphosphate of lime, 3 parts; double sulphate of potash and magnesia, 2 parts; and a mixture of equal parts air-slaked chalk lime and dry soot by measure, using a good handful, 3 or 4 ozs., per square yard. This must always be sprinkled on the freshly added soil, and not applied directly on the roots.

Little fire heat will be required by day in fine weather, shutting off the heat at about 8 A.M., and opening the valves at about 4 P.M., maintaining adequate moisture by damping the paths and other surfaces in the morning and at closing time. Maintain, however, a night temperature of 65°, and 70° to 75° in the day by artificial means. Aphides are sometimes troublesome, and may be subdued by tobacco, either in the form of vapour or smoke, taking care not to give an overdose, having the foliage dry, but the floor well damped, the latter is especially necessary where there is white fly to contend with. Soapy solutions are neither safe nor desirable for use on Cucumber foliage. For this pest and red spider fumes of sulphur are effective. The sulphur must be applied carefully, as an overdose on hot-water pipes at a high temperature is almost as injurious to the plants as are the pests.

Sow seed for raising plants to occupy pits and frames. A fair amount of bottom heat should first be secured by using the less decomposed material from Rhubarb, Seakale, Vine borders, or exhausted hotbeds, which, with about a fourth of fresh material, will afford all the bottom heat now required. The linings of beds made up some little time must be attended to, renewing as required. Maintain the night temperature as near as may be at 65° to 70°, ventilate a little at 75°, and keep through the day at 85° to 90° from sun heat. Close early so as to rise to 90° or more, and protect well at night.

Figs.—*Earliest Trees in Pots.*—The fruits of the very early small varieties are ripe, and the large Pingo de Mel, White Marseilles, and Brown Turkey are nearly so, hence the supply of water at the roots must be diminished, discontinuing syringing, and affording a free circulation of warm air, leaving a little top ventilation at night. Although watering is advised to be lessened during the ripening of the fruit, the soil must be kept moist, and a moderate moisture in the atmosphere secured by an occasional damping, but this will only be necessary in

very bright weather. As soon as the first crop is gathered syringe the trees twice daily, renewing the top-dressing, and watering at the roots with weak liquid manure. If the second crop be very abundant the fruits must be thinned so as not to overtax the trees for early forcing next season.

Early Forced Planted-out Trees.—The fruit is advancing rapidly towards the ripening stage, and must have sufficient nutriment. If necessary give the trees a thorough supply of water or liquid manure, and mulch the border with a little partially decayed, rather lumpy manure. Do not cease syringing until the fruit commences ripening, avoiding then a superfluity of moisture about the house, having a little ventilation at the top constantly, and a free circulation until the fruit is all gathered. Do not gather the fruit until it is thoroughly ripe unless it has to be packed.

Succession Houses.—Attend to stopping the shoots at the fifth joint, and subsequently to one or two; but too many side shoots must not be encouraged, as the fruit and wood require light and air for maturation. Train extensions in their full length, thinning or removing strong growths so as to admit light and air to the fruit. Attend daily to syringing the trees, and supply water as necessary to maintain thorough moisture at the roots. Renew the mulching as necessary and keep it moist, but not always saturated, so as to encourage the roots and keep them at the surface.

Melons.—After the flowers appear the atmosphere should be moderately dry and well ventilated, fertilising the pistillate blossoms when fully expanded, stopping the shoots one joint beyond the fruit. This should be persisted in daily until the number required for the crop are secured on each plant, not allowing one fruit to take the lead, but having them all on as nearly an equal swelling as possible. Do not spare the knife after the fruit has commenced swelling; but keep the principal leaves fully exposed to the light, attending frequently to stopping the laterals. Maintain plenty of moisture where plants are swelling their fruits, syringing the walls as well as the plants about 3 P.M., damping the floors several times in hot weather. Afford water or liquid manure about twice a week, never allowing the foliage to flag. The night temperature should be maintained at 65° to 70°, 70° to 75° by day from fire heat, and 85° to 90° with sun. Ventilate freely, but avoid admitting too much air at a time, so as to reduce the temperature, commencing at 75°, increasing or diminishing it with due regard to external influences.

When the fruit is full sized and advanced for ripening gradually reduce the supply of water at the roots, but not so as to cause the foliage to flag; afford a circulation of warm air, which should be rather dry during the ripening process. Cracked fruits are produced by a close moist atmosphere, and too much water at the roots. If any fruits show a tendency to crack cut the shoots about half way through with a knife a few inches below the fruit, lessen the supply of water, and also atmospheric moisture. Shade only to prevent flagging. If thrips appear fumigate on two or three consecutive evenings, or in the evening of a calm day and early the following morning. For red spider and white fly brush the hot-water pipes with a cream formed of flowers of sulphur and skim milk.

Plants in pits and frames should have the growths regulated and trained, keeping them rather thin. Plants swelling off their fruits should be well earthed, and the laterals pinched and thinned, placing the fruit on pieces of slate. Maintain the necessary top and bottom heat by linings, and cover the lights at night with a double thickness of mats.

THE FLOWER GARDEN.

Hardening Bedding Plants.—In order to make room for the more tender plants no time should be lost in hardening all Zonal Pelargoniums well established in pots or boxes. They must not be too quickly exposed to all weathers, and considering that heavy cold rains and hailstorms are very injurious to them, the best form of protection that can be used, next to old lights, are large wooden shutters. The latter are handy for a variety of purposes, and should be found in most gardens. Make good use of them for warding off cold rains as well as frosts. Avoid overwatering plants when first turned out of houses or pits. Verbenas, Lobelias, Ageratums, and Heliotropes also suffer severely if they are very cold and wet at the roots, more especially when placed in rather deep boxes, and only the strongest of the two former should be placed out of doors as yet, being then well protected. Calceolarias are much hardier, and whether placed singly in 5-inch pots or in boxes, or better still, temporarily bedded out in rich light soil, they will need little protection, but must be kept well supplied with water at the roots.

Propagating.—There is yet time to root a considerable quantity of plants, and when abundance are raised the work of arranging and planting the beds and borders is much simplified. Soft tops of Heliotropes root in a close warm frame, or in a box covered with glass and set in fairly brisk heat, in a few days, as also do Verbenas, Tropæolums, Iresines, Coleuses, and Alternantheras, stocky little plants being got ready by bedding-out time. These late-propagated plants can, if necessary, have the small pots and boxes newly emptied of the hardier or more forward plants, and if kept in gentle heat till well rooted into the fresh soil will eventually bed out surprisingly well. After pits have been cleared of early vegetables or Violets they might be got ready for propagating purposes. In some cases there will be enough heat left in the old hotbed underneath, in others a slight renewal will be necessary. With the aid of short heating material below, raise about 4 inches of fine light soil well up to the glass, and face the latter with sharp sand.

In this dibble short, soft cuttings of *Verbenas*, *Iresines*, *Alternantheras*, and such plants about 3 inches apart each way, give a gentle watering, and keep close till rooted. Shade from bright sunshine, freshen with water occasionally, and cover with mats during the night. When growing freely pinch out the points of the strong growers, and a number of capital plants will soon be fit for transplanting direct to the flower beds. This plan is particularly to be recommended where many thousand plants are required for the beds and borders, and it obviates the use of either boxes or pots.

Bedding Plants from Seeds.—*Ageratums*, *Lobelias*, *Zinnias*, *Asters*, *Stocks*, *Phloxes*, *Gaillardias*, and other plants raised from seed ought not long to be kept thickly together in pans or boxes, starvelings rarely recovering properly; all should therefore be temporarily bedded out in pits and frames (rough or otherwise), and if they do not have time to make much top growth they will form fresh roots, and will transplant all the more readily. French and African *Marigolds* sown thinly now in boxes of light soil and placed in gentle heat will germinate very quickly, and be quite large enough for the beds early in June. *Sunflowers*, notably the miniature forms, may yet be raised thus, these also moving out of seed pans and boxes without experiencing a severe check. *Love-lies-bleeding* moves well out of seed pans, and a back row of this annual is fairly effective in borders. The showy bedding *Nasturtiums* may yet be raised, and are particularly well adapted for poor hot soils. Raise the plants singly in small pots. It is not too late to sow seed of *Ricinus* and Japanese *Maize*, both being noble border plants. Sow the seeds singly in 2½-inch pots, and place in heat to germinate.

Violas.—These are most showy early in the season, but by good culture they can be kept gay throughout most summers. Young plants raised and treated much the same as shrubby *Calceolarias* are the best for summer bedding, though much may be done in the way of dividing old plants. The former must not be allowed to remain in frames or closely packed anywhere, nor should they be permitted to greatly weaken themselves by flowering now. It is not wise to delay finally planting them out till the more tender plants are ready for the beds or borders. The site for them ought to be specially prepared, being early manured and deeply dug, for they are moisture-loving plants, mildewing badly if starved at the roots. Plant out or divide and replace the old plants now, at all events where possible, and this whether they are to edge beds or to form a groundwork for variegated and bronze *Pelargoniums*, *Iresines*, and others. Mulch with either short manure, leaf soil, or spent tan, and pick off all the flower buds as they form. Thus treated they will push strongly from the base of the plants, and a good summer display result.

Dahlias.—Too often extra strong old roots are planted intact, whereas sturdy single stems, with few or no tubers, give much the best results. The former push up numerous growths, which only serve to weaken and smother each other, but the single stems branch freely and flower early and profusely. It pays well to shift rooted cuttings from small into 6-inch pots, fine strong plants being thereby prepared for the borders. Old clumps may with advantage be freely split up when the shoots are about 3 inches long, one or two tubers retained with each shoot being ample. Place these divisions singly into 6-inch pots, and keep them under glass till the fresh soil is well occupied by roots. They will make good stuff by the end of May. Plants obtained by post from a distance are necessarily small, therefore order early and establish them in pots prior to transferring to borders. This will give them a fair chance, and a much earlier display will be obtained. Even those obtained in small pots should be had early and given a shift.

THE KITCHEN GARDEN.

Globe Artichokes.—The heat and drought of 1896 has left its mark on numerous Artichoke plants. So weakly are they starting that many may fail to produce flower heads of a serviceable size. The sucker growths ought to have been well thinned, leaving three to five to each old stool, and a liberal top-dressing of decayed manure, applying this next the roots, given. Now is the time to form fresh plantations, the aim being to have a row or rows of strong young plants to take the place of the older ones as these wear out. Artichokes are gross feeders, and must have a freely enriched deeply dug root run. Detach side growths from the old plants with a knife, if possible with a few young roots attached, and plant in groups of three, a distance of 3 feet separating the groups. Those taken off and rooted in 5-inch pots under glass, planting them out before they become much root-bound, are usually the first to attain to a productive size.

Borecole, Cabbage Broccoli, Savoy.—If seeds of these winter vegetables are sown now the plants will be large enough for putting out by the time ground can be spared for them. It is possible to raise them too early, the plants becoming drawn and spindled before they can be planted. Sow the seeds thinly in the open, rather than in small patches on narrow wall borders. Early raised plants of those named, also Broccoli and Brussels Sprouts, should be picked out before they spoil each other in the seed beds or boxes. They will move best out of a finely divided soil. Prick them out 4 inches apart each way, and shelter from cold winds.

Broccoli.—It is the gross, long-stemmed plants that are the most liable to be destroyed by frosts, and the special preparation of Broccoli for the winter ought, therefore, to commence in the seed bed. Early sowing is a mistake, especially in the more southern localities. Sow thinly now in the open, and sturdy plants will be fit for their final

quarters, quite as soon as the ground in most instances is ready for their reception.

Birds and Small Seeds.—In the neighbourhood of towns, and also where there is much cover, birds are very troublesome, and never more than they have been this season. Owing to the cold wet state of the ground the seeds have been slow of germination, and many which started made such poor progress that the birds were able to clear all off the ground. The season is so far advanced that there must be few or no more failures. Either, therefore, protect with fine mesh fish netting or make the seeds distasteful to the birds before sowing it. Broccoli, Borecole, Cabbage, Turnips, and other small seeds dear to birds, should first be shaken up in a damp cloth (they stick together if heavily sprinkled with water) and be then rolled in powdered red lead sufficiently to coat them with it. Birds seldom interfere with seeds thus treated, and the red lead does no damage.

Celery.—Before the seedlings become tall and weakly the requisite number ought to be pricked out, with a view to having sturdy plants, each with a ball of soil about the roots. Select a hard base, for either ordinary or extemporised frames to stand on, and place inside a layer of decayed manure and leaves to a depth of 4 inches after it has been trampled. On this put about 2 inches of fine light soil, making all smooth and level. Prick out the Celery plants in straight lines 4 inches apart each way, sinking them to the stalks of the seed leaves. Give a gentle watering, cover with lights, and keep close and shaded from bright sunshine till they commence to grow afresh, when they must have plenty of light and air. If no glazed coverings are available shade from bright sunshine, and cover with blinds or mats during cold nights. Seeds may be sown for a very late crop.

Tomatoes.—Dull, sunless weather has favoured the production of strong leafy growth, crops neither setting well nor swelling satisfactorily. Undue luxuriance may be checked by the removal of a portion of the large leaves, but anything approaching wholesale defoliation ought not to be practised. Ventilate early, and on warm days freely, and towards midday, or when the pollen is dry, tap the supporting stakes or wires, as the case may be, or the stems with a padded stick, this effecting a good set of fruit. Plants already furnished with two or more clusters of fruit should be fed freely, soot water answering well for a change, or the later flowers may fail to set. Enough warmth should be maintained in the hot-water pipes to keep the atmosphere dry and buoyant. There ought to be no delay in shifting plants that are to fruit in greenhouses and pits into either large pots, mounds, ridges, or beds of soil.

Open-air Plants.—Directly the late-raised plants are strong enough for potting place each singly in 4-inch pots, using good loamy soil and sinking them to their seed leaves. Keep moderately warm and shaded till they have formed a few fresh roots, when all ought to be freely exposed to the sunshine and air, sturdy plants succeeding best when planted out. Late raised plants not more than 5 inches high are preferable to much larger plants in 6-inch pots, the latter seldom setting an early cluster of fruit.

Seeds to be Sown.—The state of the ground has seriously interfered with garden operations, and it is to be feared that much seed that has been sown will have perished, or slugs and other enemies have destroyed the weakly seedlings almost as fast as they come through the soil. Where only a few plants remain it will probably prove the wisest to hoe over the ground and sow afresh; but if blanks occur at intervals only sow more seed where these occur. This applies to Carrots, Onions, Parsnips, Turnips, Salsify, and the like; also to Peas, Beans, and Lettuce. Beet and Carrot seeds may be sown now in quantity, and so also should main crop Peas, with Spinach between; Kidney Beans sown on warm borders, and Vegetable Marrows singly in 4-inch pots under glass. New Zealand Spinach may either be raised singly in small pots or the seeds be sown in a pan, and the plants potted singly when large enough.

NITROGEN.—Five times as much nitrogen is lost from uncovered fields as from those that are kept covered by Clover and other mulch crops. Keep land covered with some growing crop. It is Nature's way of maintaining fertility. Vegetable and humus matter, important as they are, are not sufficient. Nitrogen can be supplied by the leguminous plants, such as Clover. They are the traps to bring the nitrogen from the atmosphere, that most expensive element when bought in the market. The bulb-shaped roots and nodules are supposed to be the result of bacterial action. Barnyard manure is supposed to contain these bacteria so essential to healthy Clover. An advantage in soiling is the gain in the amount of manure that will be made when feeding stock in the stable. They can be stabled night and day—except a few hours for exercise and sunshine—and all the liquid and solid manure carefully saved. The stable should be so constructed as to permit the entrance of abundance of fresh air. With plenty of windows so constructed that they can be readily taken out entirely, and opening all doors, good ventilation can be secured. During spring and summer it is difficult to absorb all the liquid manure, and some arrangement should be made whereby it can be conveyed to a cistern near the stable, and from there to the field. The liquid manure from horses, cattle, and sheep contains about three times as much nitrogen and potash as the solid excrement. Nitrogen is one of the most expensive plant foods, and all should be carefully saved and applied. The value and strength of liquid manure is shown by the fact that it must be diluted before applying, or it will kill the foliage of most plants. Four parts water to one of liquid manure is as strong as it ought to be used.—("Rural World.")

THE BEE-KEEPER.

LARGE HIVES.

"G. H." has turned on the search light to some purpose, and is advancing in theory if not in practice. In his notes (page 327) he makes a confession that the prodigious weight of honey (350 lbs.) from a single hive had not been obtained in his own apiary, nor in the locality where he resides. If it had one might reasonably have expected him to speak with some authority on the subject. Instead of this, however, he owns to having read in the back numbers of the Journal of a wonderful yield of honey in Scotland. It may perhaps interest "G. H." to know that I spent a few years of my life over the border. In fact I received my first lessons in bee-keeping there, and knowing what I do of that delightful country I am convinced that it is not impossible to obtain a heavy yield of honey if the all-important factor in bee-keeping—the weather—is favourable. This is only likely to happen once in a lifetime, which is as often as 350 lbs. of honey may reasonably be expected from a single stock of bees.

It may be consoling to your correspondent to know that having experimented with various sized frames and hives I have never reached the above figures, neither do I expect to do so. But if I were anxious to do so it would not be an impossibility in this county of broad acres, where our chief harvest is obtained from field Beans and White Clover, as it is a fact well known to all bee-keepers that half a dozen weak stocks will not store a surplus; but make two strong colonies of them, and if the weather is favourable they will commence at once to work in supers; and this principle may be followed out if the bee-keeper is desirous of obtaining a large surplus from one hive to the detriment of others. This plan I do not recommend. It is much better to have as many stocks as is possible in good condition when the honey flow comes, and be satisfied with a good all-round average.

LARGE FRAMES.

I do not agree with "G. H." that to be successful in bee-keeping it is necessary to have frames of extra length and depth, and the hives of extra size to hold them. I have proved times out of number that it is immaterial whether the frames are 14 inches or 24 inches in length if they are worked on rational lines. It is a great advantage to have frames all of one size in an apiary, and whatever size a bee-keeper starts with he will be wise to keep to if his bees progress satisfactorily, unless he is trying experiments. Shallow frames are more useful than those that are deep, and anything over 9 inches I consider too deep. The bees will store an extra quantity of honey instead of filling them with brood. But as the frames are required for winter stores as well as for breeding in the summer, I find the standard frame, which is 8½ inches in depth, a suitable size. The great advantage to be derived from the modern frame hive is the freedom by which the frames may be manipulated. If the frames are of an extra length they are not handled so easily as those of a more convenient size.

NUMBER OF BEES IN A HIVE.

In a previous issue (page 240) "G. H." says, "At the meeting of our Association, March 3rd, one of our members stated that day he had examined one of his hives, which has twelve frames 18 inches by 9 deep; the bees covered nine frames." Again on page 327 he says, referring to the above stock, "The hive has a vigorous queen, plenty of hatching brood, I should think by the end of April or the first week in May will crowd the hive." In some previous notes on the subject he stated the fact of his queens laying from 3000 to 4000 eggs per day.

I would like to ask him what has become of the bees. If on March 3rd the bees covered nine frames, according to his own showing they will only cover twelve frames by the first week in May. From March 3rd to that date is eight weeks; 3500 eggs laid daily will amount to 196,000. Truly this is prodigious, but where are the bees? Are they holding themselves in reserve for that cake of honey for surplus and stores? Perhaps "G. H." will explain, as it is quite beyond my comprehension to know how many bees there will be in that hive by the end of June.

I am inclined to think a mistake was made when the stock was examined early in March. If the day were warm the bees would spread over the combs, but when it became cool in the evening they would probably not cover three frames. Thus quite innocently a man may make a false statement, and instead of having his hive nearly full of bees by the middle of March it would not be in that happy position till probably two months later.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, London, S.W. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

R.H.S. Journal (Operator).—The Journal of the Royal Horticultural Society may be procured from the Secretary, R.H.S., 117, Victoria Street, Westminster, London, S.W. The price is 5s., and the postage would probably be 4½d.

Rhubarb (T. Hill).—It would be impossible for even an assemblage of members of the Fruit and Vegetable Committee of the Royal Horticultural Society to name the variety from two sections of a stalk each 2 inches long. The portions are the colour of, and sharply ribbed-like, the London Early Red. If half a dozen stalks with leaves arrived in a fresh state the variety might possibly be named by comparison in the collection at Chiswick. We are unable to inform you from whom the variety Elford Rose can be obtained, but mention it in case any of our readers can supply the information. The favourite variety for increase by many extensive growers of Rhubarb for the supply of London is Hawke's Champagne. It is early, pink when cooked, and of excellent quality. The work on gardening you mentioned has been long out of print, as have also the numbers of the *Journal of Horticulture* about which you inquire.

Collapse of Cucumber Plant (J. G.).—The stem is split above the soil, and more or less decayed to a height of 6 inches, being quite rotten at its junction with the soil, thus cutting off the supplies of sap and causing the collapse of the plant. Part of the root-stem is also destroyed, but only to the extent of about 2 inches, the radical root and the side roots being perfectly healthy. There are not any nodosities on the roots, such as are caused by eelworm, and even the root-stem is not swollen, as usually occurs under attacks of nematoid worms. The cause of the misfortune is, therefore, the decay of the stem at the collar. This is usually attributed to canker caused by damp, and the preventive and repressive measures prescribed in such cases are keeping water from the stem and rubbing quicklime into the affected part. This acts well if taken in time. In the present case, as no attacking foe was visible to the naked eye, the microscope was brought into operation. On the part infected above ground nothing was found in the shape of outgrowths, but in the tissues the mycelial threads of a fungus were visible enough, penetrating the living tissues, ascending the stem, and causing the cells to become brown and dead. This was the cause of the mischief, and the parasite had entered the plant at the point on the root-stem where the radicle issues from the seed. The hyphæ, or young mycelial threads of the fungus, in the living tissues are those of *Botrytis cinerea* var. *sclerotiphila*, Sacc., which in fructifying form springs from an externally black sclerotium, once called *Sclerotium durum*. It is the active form of the smother fungus, *Sclerotinia sclerotiorum*, Mass., and one of the most malignant to Beet, Carrots, Potatoes, and Turnips outdoors, Cucumbers, Melons, and Tomatoes inside. This, then, and this only, has been the cause of your plant decaying in the stem. In the decayed parts of the root-stem, however, were found some eelworms, the blunt-shaped species, *Tylenchus obtusus*, Bastian, but not in living tissues, the roots not infested by the fungus being perfectly normal and healthy. There was also a mite, the true root-mite, *Rhizoglyphus echinopus*, Clap., but this was not connected with the living tissues of the roots. It was the perfect eight-legged form, which is far more difficult to kill than the six-legged or larval form—indeed, it lived a considerable time in a solution of aniline, 1 in 20 parts water, and is mentioned as showing the importance of early treatment. The compost was also examined, and found to consist largely of vegetable matter in a state of decay, and, despite the baking before using, contained the sclerotia of the fungus,

also eelworms and mites. This we consider the source of infection. Nothing could possibly result from the application of Thomson's Vine manure but benefit to the Cucumbers and prejudice to the micro-organisms. As to the baking of soil, we have found that a temperature over 125° will kill eelworms, 145° mites, and 212° the sclerotia of fungi. Possibly unbaked soil has been added since the plants were placed out; in any case the micro-organisms were in the soil and ruined the plants. When the fungus or the eelworms have entered the tissues of the stem and destroyed the cambial cells the case is beyond remedy. For saving the remaining plants we know of nothing better than Little's soluble phenyle, 1 part in 96 parts water = 1 gill ($\frac{1}{4}$ pint) to 3 gallons of rain or soft water, applying as in ordinary watering, and repeating as required. If taken in time it acts well against root-fungi, eelworms, and mites.

Insects on Peach Tree Branch (D. M. L.).—The insects on the Peach tree twig are very fine examples of the Filbert scale (*Leucanium hemisphericum*), which, when full grown, and before emitting cottony matter from beneath the scale, is a quarter of an inch long, three-sixteenths of an inch broad, and one-eighth of an inch deep or high. It is rather of uncommon occurrence in this country, but may sometimes be found on Apricot trees grown under glass, also on Camellias. When the scale becomes mature, which occurs when the eggs have been produced in a cottony substance beneath the "shell," the insect emits from the posterior end a white flocculent substance, and this contains hundreds of pale brown or reddish bodies, just visible to the naked eye. In the course of a few days these emerge as six-legged creatures with somewhat long horns and caudal appendages, roam about, and soon fix on a smooth part of the bark of either a young shoot or not very old wood, push in a beak, and become fixed to the place for life. To prevent this you must at once remove the scale and eggs in the cottony matter; they may be placed in an old tin containing a little petroleum, and finally burned. Then to make sure of any that may have escaped in the early predatory stage, apply an insecticide, any or all of those advertised being effectual and safe if the instructions are carefully followed. If you prefer a home-made one place 1½ lb. of soft soap in an iron pan with a gallon of soft water, and dissolve by heating and boiling. When dissolved and hot remove from the fire and add half a pint of petroleum, stirring briskly till amalgamated. Dilute to 10 gallons with hot soft water, and when cooled to 90° to 100° apply with a syringe, or preferably with a spraying apparatus for sake of economy. If this be repeated in ten days or a fortnight we do not think you will be further troubled with the scale. Of course, it may be re-introduced, but that must be guarded against by having the source whence it came found out and the pest eradicated there.

Foreign Seeds (Seeds).—*Canna indica*, which few gardeners do not know and grow, is a very useful plant for greenhouse decoration and sub-tropical or other methods of summer gardening. The seeds should be sown in heat in a warm house or Cucumber bed. When the plants are large enough to handle pot singly and grow in a rich and porous compost, such as equal parts turfy loam and decayed manure with a little peat and some sand. *Cesalpinia echinata* is an ornamental stove evergreen tree, not much grown on account of the space required and the time the plant takes to flower. A mixture of loam and leaf mould suits it. The flowers are produced in racemes, pear-shaped, and yellow with red, very beautiful, as most of the Leguminosæ are. The seed should be sown in strong heat. *Anona muricata* is the "Sour Sop" of the West Indies, a stove evergreen shrub or tree growing about 15 feet high. It thrives well in rich loamy soil mixed with a little peat. The seeds grow readily if sown in pots and plunged in a hotbed. It is grown for its fruit. *Passiflora foetida* is the Wild Water Lemon of tropical America, an annual or sometimes, but rarely, perennial. It requires a stove. The flowers are whitish, the corona variegated with purple and blue. Treat similar to Cucumbers or Melons. *Abrus precatorius* is a very ornamental and delicate much-branched deciduous stove climber, the roots having the properties of the common liquorice. The flowers are butterfly-shaped, pale purple, and disposed in axillary clusters. The seeds should be sown in heat, and the plant requires strong heat to keep it healthy and to flower it well. It is called the "Prayer" plant, from the Buddhists using the bright scarlet seeds, with a black spot at the base, for making rosaries. Sandy loam best suits it. *Psidium Guava* is a low tree, evergreen, and desirable for its aromatic fruits. It requires a stove, thriving best in a compost of sandy fibrous loam and a little leaf mould or old cowdung with some sand. Perfect drainage must be provided. The yellow globose fruits are produced abundantly when the plant becomes sufficiently large, but seedlings come slowly into bearing. It is esteemed for its fruit—the Guava of renown. *Tephrosia candida* is the Indian Hoary Pea, a low stove shrub, flowers reddish or white, produced in terminal and lateral racemes rather copious, the standard being very silky. It thrives in a compost of sandy peat and leaf mould. *Bixa Orellana* yields the drug called Annotta, which is prepared from the red pulp that covers the seed, and is used in preparing chocolate, by farmers for colouring cheese, and for dyeing silks orange or yellow. It is a stove evergreen tree, growing 30 feet high. Seedlings are a long time before they flower. Sow in bottom heat. The flowers are peach-coloured, and borne in terminal clusters or corymbs. A compost of loam and peat suits it. *Acacia glauca* is an evergreen shrub, 5 to 10 feet in height, and produces abundance of white flowers, stalked, spikes globose, axillary, usually twin. The seeds should be sown in sandy peat in gentle heat. When established the plants grow well in a greenhouse. *Desmodium gyrans*, the Moving or Telegraph Plant, a great curiosity, the lateral leaflets moving up and down, either steadily or by

jerk, the movements being most marked during bright sunshine. It is a stove plant of easy culture in a compost of sandy loam and peat. The flowers are violet, borne in numerous racemes disposed in a panicle. The plant grows 1 to 3 feet high. A brisk bottom heat is required for raising the seedlings and pushing the plants along. *Artocarpus incisa* is one of the noblest of the Nettle family, the True Bread Fruit, a stove evergreen tree, growing 50 feet in height, the leaves being 2 to 3 feet long, deeply lobed or incised, deep green on the upper surface, pale below. It forms a very distinct and ornamental stove plant. The extraordinary fruit is produced from the axils of the leaves in large globular heads, and is highly valued by the South Sea Islanders as an article of food. Perfect drainage is a first consideration, as the plant requires copious supplies of water, a very high and moist atmosphere, a compost of two parts rich loam and one part leaf mould, with a free admixture of sharp sand. Brisk bottom heat is required for the germination of the seeds. *Thevetia nerifolia* is the Exile Oil Plant, which has linear glabrous shining leaves about 3 to 6 inches long. It develops into a shrub growing 12 feet in height. The flowers are saffron-yellow, about 3 inches long, produced in sub-terminal cymes much shorter than the leaves, and sometimes one-flowered. It thrives in a compost of fibrous loam with a little leaf soil and some sharp sand, in a stove temperature. Pitango Cherry we do not know—at least under that name. Perhaps some of our correspondents may oblige with information.

Chemical Manure for Strawberries (T. G.).—As you do not want an expensive manure, but an economical one, and quickly acting, as it must be to effect the object you have in view, nothing would serve you better than nitrate of soda, which should be 95 per cent. purity, and crushed quite fine on a hard floor before use. Apply 1 oz. per square yard, or 2 lbs. per rod, taking care not to scatter it on the young leaves and crowns, especially when these are wet, or it may blacken them. If the soil contain sufficient phosphoric acid and potash in available form, as we think will be the case from the ground having been heavily manured, there will be no need to use anything but the nitrate of soda and the liquid manure you propose, which we presume is that of stables and cow house. You may, however, if you desire, employ the following mixture:—Mineral superphosphate (37 to 39 per cent. phosphate of lime, soluble), 3 parts or lbs.; muriate of potash (80 to 85 per cent. purity), 2 parts or lbs.; nitrate of soda (95 per cent. purity), 1 part or lb.; mixed, applying 4 oz. per square yard, being careful not to use it over the foliage or crowns of the plants. This should be given without delay, pointing in very lightly, or hoeing or raking, and when the fruit is set and commencing to swell, supply nitrate of soda as before mentioned. If you supply proper moisture the crop ought to be, other conditions being favourable, a very heavy one, and the fruit large. Be careful, however, not to overdo either the manuring or the liquid applications, for the plants can only give superior fruit with abundance of healthy and active roots, therefore you must exercise judgment in the use of the fertilisers, only applying half the amount named at a time if the roots are near or at the surface.

Vine Growth Diseased (D. M. L.).—The point of the shoot was blackened, and more or less covered with a white mould, the downy mildew of the Vine (*Peronospora viticola*). It is a minute parasitic plant, that develops at the expense of the tissues of the Vine, thus causing the blighting of the leaf and decay of the fruit. It attacks all the green parts of the Vine, including the young shoots, as well as the leaves and bunches, and, like other fungi, is reproduced by means of spores. There are plenty of these in your specimen, and one of them speedily divided in a drop of water, and each particle (zoospore) escaped by an opening in the spore wall. It moved about in the water for a few minutes by means of its head and tail appendages (hairs or cilia), rested on a portion of leaf, pushing a germ tube (like the radicle of a seed), which entered a stoma or transpiration opening, and passed entirely out of sight. It is well to see these things, and find by frequent examination that the tube continues to grow, divide, and push other portions (hyphæ) between the cells of the leaf, forming the mycelium, readily seen, in a section, traversing the intercellular spaces, and as there is little nourishment to be had there, this mycelium pushes minute processes (haustoria) through the cell walls, and absorbs the cell contents. After this mycelium becomes strongly developed it pushes growths outwards, either through the stomata or ruptured epidermis, which are the erect hyphæ or fruiting branches, and these (conidiophores) bear upon their tips, in a branched head, not unlike a bunch of Grapes, small oval bodies (conidia) or spores. The outgrowths or mildew, visible to the naked eye, is composed of these fruiting branches and their spores. The latter are shed when mature, and scattered far and wide by every puff of wind. If they alight on the leaf or other green part of a Vine, and there is sufficient condensed moisture, they at once proceed to form zoospores, and these to act on their own account, as before described. It is well to note, however, that the "fruit" only develops under favourable atmospheric conditions, such as warmth and a soft glow of moisture, hence the mycelium may, as in your leaf, exist in the affected parts of the Vine for some time before the outward manifestation of its presence or mildew occurs. In the diseased tissues another form of spores, called "resting," are produced, and in these the fungus passes over from year to year. As regards treatment, the infested parts, so far as these are browned or blackened, should be cut away and burned, and the Vines dusted with any of the advertised fungicides in powder, such as anti-blight and fostite, using a bellows apparatus and the least possible coating. We give a fuller reply than usual, as the downy mildew or brown rot is becoming too prevalent in this country.

Microscope for Examining Fungoid and other Micro-organisms (H. T.).—Mr. Abbey says there is no need for a costly instrument for practical and really useful work. There are no mysteries about the subject, nor are they more difficult to learn than the science and practice of growing Cabbages. A good garden or seed microscope that may be used as a simple and compound instrument for the various requirements of gardeners is all that is required. He further says it is better to invest in the United Horticultural Benefit and Provident Society, and also make provision for old age by becoming a life member or annual subscriber of the Gardeners' Royal Benevolent Institution than in costly microscopes and highly scientific works. He has a small microscope that may be packed in a mahogany case 4 inches by 3 inches and 1½ inch deep, and it only cost £1 5s. It shows all fungoid pests of crops, eelworms, and mites, as large as need be, and was had from Mr. L. P. Casella, 147, Holborn Bars, London, E.C. If you want a thoroughly reliable English-made instrument we advise a Student's Improved Binocular Microscope, costing £6 6s. To discern micro-organisms of the bacterial class you will need a power of not less than 750, when they will appear as mere specks, and without considerable practice are difficult to make out. The instrument would, with reasonable care, last a lifetime, and certainly be all you could desire in your practice as a gardener.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruit or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. *They should be sent on the first indication of change towards ripening.* *Dessert Pears cannot be named in a hard green state.* (M. P.).—1, Bess Pool; 2, Dummelow's Seedling, but known as Normanton Wonder in your district; 3, Gooseberry Apple; 4, Lord Burghley; the Pear is Bergamotte Esperen. (Felix).—The Grape is without doubt Lady Downe's, unusually fresh and firm for the season.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, at being often difficult to separate them when the paper is damp. (C. F.).—1, Arabis alpina; 2, Aubrietia Leitchii; 3, dead. (W. J. H.).—Auriculas are florists' flowers that can only be named by comparison in a large collection, such as that of Mr. Douglas at Great Bookham. (A. T.).—The Narcissus is bicolor Horsefieldi, and the Muscari is botryoides. (C. S.).—No. 1 is one of the Broom Rapese (Orolanche), a leafless herb, which lives as a parasite on the roots of other plants; 2, Prunus padus (Bird Cherry). (W. H. Y.).—Oncidium flexuosum; a form of Adiantum trapeziforme, but the specimen is not large enough to distinguish the variety.

ROYAL METEOROLOGICAL SOCIETY.—The monthly meeting of this Society was held on Wednesday evening, the 21st inst., at the Institution of Civil Engineers, Great George Street, Westminster, Mr. E. Mawley, F.R.H.S., President, in the chair. Mr. W. H. Dines read a paper on "The Relation between Cold Periods and Anti-Cyclonic Conditions of Weather in England during the Winter." There seems to be a generally accepted belief that anti-cyclonic conditions during the winter are likely to be accompanied by exceptional cold, but in so far as England is concerned the author's observation has led him to the opposite conclusion, and he always expects a frost to break up as soon as the barometer gets much above 30 inches. To test the truth of this theory he tabulated the height of the barometer during all the cold periods during the three winter months of the fifty years 1841-90. Out of seventy-four frosts he found that sixteen only had a pressure exceeding 30.20 inches, and the majority of these were of very short duration. Thirty-three, or less than half, had a pressure exceeding 30 inches; twenty-one had a pressure below 29.80 inches, and these included almost every frost in the period remarkable for its length or severity. A paper by Mr. A. Lawrence Rotch of the Blue Hill Observatory, Mass., was read, describing the use of kites in that Observatory to obtain meteorological records in the upper air. A paper by Mr. A. B. MacDowall on "Suggestions of Sunspot Influence on the Weather of Western Europe" was also read. The author believes that there is a tendency to greater heat in the summer half year, and to greater cold in the winter half year near the phases of minimum sunspots than near the phases of maximum, the contrast between the cold and heat of the year thus tending to be intensified about the time of minimum sunspots.

GARDENERS' CHARITABLE AND PROVIDENT INSTITUTIONS.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—*Secretary*, Mr. G. J. Ingram, 50, Parliament Street, London, W.C.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—*Secretary*, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

THE TURNIP CROP.

THE time for sowing Turnips will soon be here, and before considering what are the best varieties to grow and the best methods of cultivation, we should like to briefly discuss what is the real value of the Turnip crop when it is grown. We have been much interested by a controversy in a contemporary between

an unknown contributor and an agricultural professor as to the value, great or small, of this crop.

The professor quotes £1 per acre as a price at which Turnips can be bought for consumption on the land, and argues that they will pay the farmer to grow at such a low price if he gets plenty of dry food consumed with them so as to highly enrich the soil for the succeeding corn crop. On the other hand the anonymous gentleman repudiates the value of eating Turnips on the land, but claims that he can make £10 per acre of them to cart off for sheep on grass, and publishes a balance-sheet in support of his contention. The weak points about his system are that 10 acres of useful—nay, we might say good—grass are required for the winter months upon which to consume 1 acre of Swedes; also that he buys his sheep on November 1st and sells them out again on March 1st at a profit of 15s. per head, or nearly 1s. per head per week.

Of course if this can be done year by year there would be a fair profit—a very good profit on grazing sheep on roots. But such a profit could not be made during a series of years unless it were in a district unsuitable to the growth of good Turnips, and where a good crop of them would be correspondingly valuable. So much depends on locality as regards the value of Turnips. In the grass districts of the northern counties, and in Scotland, the Turnip acreage is a small one compared to that of grass and other crops, and it is not therefore surprising to find that roots in those parts fetch high prices. On the other hand, in arable counties where the area under Turnips is a large one, it is not uncommon to find fair crops sold at £1 per acre, and in a plentiful season, with dear sheep, they are often given away, as spring approaches, on condition that they are consumed on the ground.

But what is an acre of Swedes worth to an average farmer? This is a very difficult question to answer, the roots being so intimately allied with grass, Clover, and straw as food for stock. It is easier to ascertain the value of roots when used by sheep than when used by cattle; but the seed and grass pastures used by the sheep during the year must be all brought into account, and must have a fair share of the proceeds.

In order to work the matter out in figures, we will take as an example a farm of 400 acres—300 arable, 100 grass. Such a farm should be self-supporting, and independent of the fluctuations of markets. The 75 acres of seeds which there would be under the four-course system would carry about 200 ewes, with about 250 lambs; these would require fully 60 acres of good Turnips for the following winter, and allowing for losses, there should be 230 hoggs to sell in the spring. These should realise about 50s. each in the wool.

230 hoggs at 50s.	£	s.	d.
						575	0	0
Now let us deduct expenses—								
Shepherds' wages	£52	0	0		
Man and lad, twenty-six weeks	28	12	0		
Loss on ewes (lambing)	20	0	0		
Grass and Clover for lambs after weaning	30	0	0		
Two-thirds cost of artificial foods	50	0	0		
						180	12	0
						£394	8	0

The offal account (carcases and skins) would pay for the fencing, leaving £394 8s. to allot to the credit of the seeds and Turnips. £2 10s. per acre would be a very liberal price for the seeds, so if we deduct 75 acres at 50s. (£187 10s.) we have £206 18s. left to the credit of the 60 acres of Turnips and Swedes, or as nearly as possible £3 10s. per acre. As this would barely cover the cost of growing the profit would depend entirely on the success of the succeeding corn crop.

This brings us face to face with a difficulty, and one of the most serious that arable farmers have to contend with. The land being well farmed, and a fine crop of roots having been grown and

consumed on the land, should the season be a favourable one a fine standing crop of Barley or Oats may be secured, and therefrom a fair return for the two years' outlay; but should the season be a wet one the result may be a mass of twisted and rotten straw, most expensive to harvest, with a yield of grain small in quantity, light in weight, and only fit for feeding purposes, whilst the young Clovers will be conspicuous by their absence, having been completely smothered. This difficulty has led many thoughtful farmers to grow two white crops after Turnips, and to sow their small seeds with the second one, which, not being too heavy, gives the young seeds a fair chance.

We are convinced of one thing—that the loss of the Clover plant is a most serious misfortune; there is not only the loss of pasturage, but Clover is such a recuperative crop that we would rather lose our Turnip crop than have a bad piece of seeds, as we think the Turnip crop of less importance, valuable as it is.

There is another point of value in connection with Turnips that we have not mentioned, that is the cleaning of the land. If we did not grow Turnips the land would have to be fallowed occasionally, and if we can make as much of our Turnips as they cost we have got our land cleaned for nothing. This must never be lost sight of, as it is of little use manuring if the land is full of weeds and twitch.

WORK ON THE HOME FARM.

Weather conditions are quite those usually associated with the month of April, except that the showers have hardly brought with them the warmth we had expected and been hoping for. Still, things are better than they were. We have had no more sharp frosts, and the appearance of the young Wheat as well as that of the pastures is much improved; keeping, however, is now very scarce, and the markets for all kinds of stock, with the exception of prime fat cattle, are very much depressed.

The land is working down well, and we have the promise of a good tilth for Turnips and Mangolds; but there is no chance of getting twitch burnt at present, and it has all to be gathered up and carted off. We are thankful to say that there is not much of it, but what there is is very full of life and growth, and being in small bits it is a tedious job raking and gathering it up.

The Potato ridges were rather rough, so we are harrowing them down with the ridge harrows and shall very shortly ridge them up again with a light earthing plough. Potatoes thrive much better in loose, freshly moved ground, and the labour will be saved in the hand-hoeing, which is always more expensive than horse work. Earthing up now is also a safeguard to the Potatoes, if they are early ones, against the serious damage they may sustain from late frosts if they get their noses above ground too soon.

We are getting the cattle to sleep out now, but it is cold for them and they require careful watching. The lambs' tails have been shortened, and we have docked the ewes—i.e., trimmed the wool from the back of the thighs and round the tail; this is a necessary operation at this season, but should not be done when the weather is very cold, or exposure of the udder may bring on downfall, a very dangerous complaint amongst ewes.

REMARKS.

18th.—Brilliant early, and generally sunny all day; fine night.
19th.—Generally sunny in morning; overcast afternoon, and rain in evening.
20th.—Rain till 4 A.M., and overcast till 1 P.M.; generally sunny after.
21st.—Dull, with almost continuous rain or drizzle till 5 P.M., and overcast night.
22nd.—Drizzle in small hours; overcast and dull till 10 A.M., generally sunny after.
23rd.—Fine with much bright sun, but frequently cloudy.
24th.—Cloudy at times, but much bright sunshine.
Another week, the character of which is almost precisely that usual for its date.
There was no frost even on grass.—G. J. SIMONS.

12 Very good Double kinds, mixed colours, 6/-; 6, 3/6.

CHRYSANTHEMUMS.

12 Grand new Japanese, 1897, to include Yellow Madame Carnot and Western King, for 30/-.

6 To include the above two, 20/- Yellow Madame Carnot, separately, 10/6 each.

12 Very finest 1896 kinds, 7/6; 6, 4/-.

12 Beautiful kinds, specially selected for cutting, 4/-.

12 New Early Flowering Japanese, for Pots or Garden, 7/6.

12 Good Early Flowering Japanese, for Pots or Garden, 4/-.

12 Beautiful Early Flowering Pompons, for the Garden, 4/-.

12 Beautiful Single kinds, A1 for cuttings, 4/-.

DAHLIAS.

12 Best Cactus kinds, 3/6; 6, 2/-.

12 Best Show and Fancy, 3/6; 6, 2/-.

12 Best Pompon, 3/6; 6, 2/-.

12 Best Singles, 3/6; 6, 2/-.

FUCHSIAS.

12 Finest Double kinds, including Rose and White Phenomenal and Madame Carnot, the Giant White, 4/6; 6, 2/6.

12 Finest Single kinds, including Royal Purple and Princess May, the prettiest Fuchsia raised, 4/6; 6, 2/6.

GLOXINIAS.

6 Finest named kinds, 5/-; 3, 3/-.

6 Finest Spotted, 3/- 6 Finest Selfs, 3/-.

HELIOTROPIUM.

6 Best named kinds, 2/6; 3, 1/6.

PELARGONIUMS.

12 Show and Decorative kinds, grand stuff in 5-inch pots, 12/- (these will make a big display).

12 Grandest new Single Zonals for 1897, including Mrs. W. Winn, the nearest Blue, 20/-; 6, 10/6.

12 Finest new Single Zonals, 1896, 10/-; 6, 5/6.

12 Finest Single Zonals, 1895, 6/-; 6, 3/6.

12 Finest Single Zonals, 1894, 4/-; 6, 2/6.

6 Finest Single Zonals, Souv. de Mirande type, including Madame J. Chretien, 3/-.

12 Finest Double Zonals, selected from 1897, 1896, and 1895, to include Apple Blossom, Golden Gate, and Double H. Jacoby, 7/6; 6, 4/-.

12 Very fine Double Zonals, 4/-; 6, 2/6.

6 Grand new Double Ivies, including Achievement (cross between a Zonal and Ivy) and Mrs. C. Bick, Magenta, distinctly shaded Blue, 7/6.

12 Grand kinds, 4/-; 6, 2/6.

DOUBLE PETUNIAS.

12 Finest Named kinds, including Mrs. D. B. Crane, the Electric Blue, 6/-; 6, 3/6.

All Orders are Post or Package Free for Cash with Order.

Journal of Horticulture.

THURSDAY, MAY 6, 1897.

EXTRA HELP IN GARDENS.

MORE perhaps than at any time during the past twenty years are gardeners in large establishments and small groaning under the pressure of work which daily seems to become more crushing. Scheme as they may, strive as they will, early, late, and all the time of daylight, they cannot master the position. They long, too often in vain, but all the same keep longing and hoping for a little help to extricate them from their difficulties, and put things straight for the summer.

Hardworking and overworked gardeners know that being behindhand at the present time means a scuffle all the season, and they deplore their inability to do what they wish for their own credit and the satisfaction of those whom they serve. A little extra help, such as a man or two in small gardens for a fortnight, or a "gang" from the "estate" in large establishments, would be a boon indeed to many an earnest man, nor would it be to his advantage alone or even chiefly. When arrears are brought up at this season of the year a gardener has a much better chance than he would otherwise have of keeping abreast of routine work, to the distinct advantage of the various crops in the fruit and vegetable departments, while the several plants that he is expected to grow can have the attention they need at the proper time. This is most important. Equally so is a mastery over work in respect to walks, lawns, and general neatness. Gardens and pleasure grounds are then kept in a manner which renders them in the highest degree enjoyable and satisfactory to all—owners, gardeners, and visitors.

When work cannot be done at the proper time, but has perforce to wait for ten days or a fortnight, not only does much of it take twice the time to complete, but it is not then done half so well as it should be. The full truth and significance of this can perhaps only be really appreciated by gardeners, or those proprietors who take pride in their home surroundings, and have been closely observant of the influencing conditions. Fortunate are gardeners whose duty it is to serve those who see as clearly as themselves not only the condition of things at the moment, but also the eventual outcome of these conditions;

and doubly fortunate is it when those garden lovers with knowledge also possess the means for affording what may be termed grants in aid during a time of pressure, and the benefit of which would be seen and felt all through the season. It is common to make such grants, both in many public parks and private gardens, at this period of the year, and this, though quite unknown by admiring visitors, largely accounts for the cleanliness and orderly condition of the enclosures which are so much admired.

That late work involves the greatest cost in time-absorbing labour, and gives the least satisfactory results is seen in all the departments of a garden, and nearly all the duties of the gardener. Let, for instance, walks become encrusted with weeds: they are not only glaringly unsightly, but thrice the time, and often very much more, is required in making them presentable than would have sufficed for the prevention of the evil, especially if the gardener had at his command, before other work became pressing, one of those cheap preparations by which walks and drives are kept free from vegetation throughout the year.

Let lawns and verges be left untended ten days or more beyond the proper time for the use of the machine and shears, and note the heavier labour required, and extension of hours occupied while the garden during the period of enforced delay has had a more or less unkempt appearance; and even when the work is at last done the effect on the lawn is never the same as if it had had the right treatment at the right time.

Let beds, borders, and vegetable quarters become masses of luxuriant weeds, each day increasing in height and vigour till they almost master the hoe, and hand-pulling has to be resorted to; then ten hours have to be spent for clearing a given area when one hour or less would have amply sufficed if the hoe could have been run through the surface periodically when the weed seeds were germinating. Moreover, by this practice the richness of the soil is conserved and even enhanced, whereas the great gangs of thieves, the weeds, drain it of its nutriment to the prejudice of useful crops or whatever it may be desired to grow.

Let seedling lines in the vegetable garden be left unthinned too long, then the superfluous plants themselves become robbers, taking from the soil its virtues and giving nothing in return; but this is not all, they spoil those plants which should remain, and which, if afforded the requisite space to develop, would utilise the resources of soil and air, return profit to the owner, and be creditable to all concerned.

It is precisely the same with overcrowded plants which are being raised for the beautification of gardens. If not thinned or transplanted when they ought to be, and often cramped for they are more and more weakened every day, soon culminating in miserable spindlings, and mere apologies for the plants they ought to be. There are, or soon will be, millions of plants on the road to ruin through the want of timely relief. Gardeners know this quite well, and not a few grieve over the evil they cannot avert, because one pair of hands cannot be engaged in three or four occupations at once, each about as urgent as the other. Something must thus of necessity wait, and get worse daily in the struggle to escape from the crowd.

Gardeners also know full well in the cultivation in pots of various plants which they are expected and hope to produce in the best condition, that if these plants, no matter what they are, cannot be afforded more root room at the right time, they must suffer; and if they perforce must be left week after week, either by want of materials or the urgent demands of other duties, it is well known that anything like the success the growers hoped for and expected when the year was young becomes a practical impossibility. Neither plants nor their cultivators can have a fair chance under those conditions, and both are often objects to be pitied rather than envied.

Just one other example may be noted of the loss of time, and what might be valuable produce, caused by delay in an important operation in gardening—namely, the thinning of Grapes.

Let this be done at the right moment, and five bunches may be thinned in the time that is necessary for thinning one bunch when the berries are wedged. Then think of the drain on the Vine of the myriads of useless berries which have been permitted to hang so long, and of the "mauling" of the bunches that have been neglected—in some instances it may be, perhaps, through want of energy and promptitude, but in many cases certainly through overwhelming pressure.

A week ago we found two men sedulously engaged in thinning Grapes till the last hour of daylight permitted. "We can only touch them," the senior said, "from daylight till seven o'clock in the morning, and again after six o'clock in the evening. The conservatory *must* be done before breakfast, then we have 3 acres of pleasure grounds, over an acre of kitchen garden, five houses for plants, Cucumbers, Melons, and Tomatoes, besides pits and frames. We can do nothing in Grape-thinning and Vine-dressing in the daytime, and the thinning nearly beats us." Then, in reply to a question, he went on, "Overtime! No, we are not paid; it has never been mentioned, and I should be satisfied if I could keep the place to my mind and have really good houses of Grapes." That represents the earnest, zealous, devoted, active British gardener, and his employer has probably no conception of the pressure under which his two men work.

This example of diligence in duty came to mind when Mr. Wilks, in his earnest speech in response to the toast of "Gardeners and Gardening," at the dinner of the Royal Gardeners' Orphan Fund. It was to the effect that no men worked so strenuously over so many hours for the emoluments they received as did gardeners. Impelled by devotion and by zeal they sought for knowledge and applied it from dawn till dusk in summer, and watched the fires through the midnight hours in winter lest harm should befall the tender products which they loved as if they were their own. For gardeners there were no such luxuries as eight hours a day. There were no strikes among them; few holidays for change and repose, or brilliant rewards for faithful loyal service, and duties discharged so well.

The words were not uttered to tickle the ears of working gardeners, for few of them were there; and it was all the more pleasing to note the responsive cheers of employers of gardeners, of whom the meeting was so largely composed. It is clear the work of gardeners is appreciated, if not in all cases adequately recompensed. Then Mr. Wilks went on to make significant allusions which were not of a cheering character for gardeners during this year of rejoicing on the occasion of the great reign of our good and gracious Queen. With the most worthy object of doing honour in various ways to the remarkable event, he feared some diversion of means usually devoted to gardens, and even to charities, might occur; in fact in one great organisation of rescue (of "beggars and outcasts," for whom the Princess of Wales is pathetically pleading) known as Dr. Barnardo's homes, a fall of £4000 was already a melancholy fact, and the total loss during the year was expected to amount to £6000, because of the diversion indicated.

It can only be hoped that there may be, as in innumerable instances there will be, local compensations, and as gardens will contribute largely to the joyousness of gatherings, public and private, it is much to be desired that eminent, faithful, and hardly pressed gardeners will not be forgotten; but that where a little extra help can be afforded to worthy, striving men it will be granted, and that is why this reminder is given of the existence of great, and in some instances of almost crushing pressure in gardens at this period of the year. In numbers of cases relief could be given at a comparatively small outlay, especially if given in good time. Then would the season be made happier to the gardener, while the gardens would afford the greater satisfaction to those who may be privileged to enjoy them during this memorable year.

It is a little singular that the first MS. examined after writing

the foregoing paragraphs was the following, in which it will be perceived Mr. Wilks adduces further evidence of the effects of the Diamond Jubilee.

THE R.H.S. FRUIT SHOW—£100 MISSING.

I feel inclined to head my letter, "Lost, Stolen, or Strayed, £100," for though not "lost" or "stolen" the £100 required for the autumn show of British grown fruit certainly seems to have "strayed" into the all-devouring capacity of the many-mouthed Diamond Jubilee projects. At any rate, it is missing.

You will remember that when the autumn fruit show, which had been held from time immemorial at the Crystal Palace, had fallen through, the R.H.S. offered to revive it as a show of British grown fruit, with prizes to the value of £250, on condition that those interested in the encouragement of fruit growing in this country would subscribe not less than £100 towards the unavoidable expenses.

For the last few years this £100 has been forthcoming, and magnificent shows have resulted, teaching thousands and thousands of spectators what fine fruit can be grown in Great Britain, and instructing very many planters as to the best varieties with which to stock their orchards and gardens.

Alas! this year of especial grace the £100 has strayed; it is not—or at least, is not as yet. Letter after letter reaches me to the effect—"Very sorry, but am so bled with Jubilee projects that I cannot help this year." In fact Peter is to be robbed in order to pay Paul.

May I be allowed to appeal to all interested in British fruit not to let our grand annual show fall through for lack of £100? Immediate help is wanted, as the schedule is all ready for issue—all ready with this one all-important exception.—W. WILKS, Sec. R.H.S., Vicar of Shirley, Croydon.

Perhaps Mr. Wilks may consider the advisability of inaugurating a Victoria Medallists' dinner. It seems to have leaked out that there are to be sixty of them (not dinners, but Victorians), and surely they could raise half the £100 or more.

GERMAN SHOWS THROUGH ENGLISH SPECTACLES.

BERLIN.

WHEN we get that Horticultural Hall on the Thames Embankment, with, presumably, gardens thrown in, we shall be in a position to work up our exhibitions in the same style and with the same effect as our German cousins do theirs. Until that happy time arrives we must grovel instead of soar. The great exhibition which took place in Berlin from the 28th April to the 9th May came as a sort of electric shock to one fresh from a Drill Hall meeting. Of course, it will be said that there is no fair comparison, the one being a special affair, and the other part of a yearly programme, and that is certainly so. Still, London is London, and Berlin is Berlin, and writing from the point of view of the general spectator, who ought to discriminate, but does not, London is unquestionably "in a fog."

To get an idea of the conditions of the German Show we must begin by taking a 2d. steamer from the Temple Pier down to Battersea Park. We must then proceed to provide the river front there with a series of handsome permanent exhibition buildings, interspersed with trees and shrubs (throwing in, in a merely casual way, a spacious and well patronised refreshment bar); then we are well on the way. Battersea Park in Berlin becomes Treptower Park, the Thames becomes the Spree. There are differences in the nursemaids, there are differences in the lady cyclists, there are differences in the noblemen who navigate the barges down the river; still, the parallel is plain enough, and to complete it we have only to include a few cheap steamers swaggering offensively up and down.

However, it might be well to begin at the beginning. Reaching the Park at Treptow from the Friedrichstrasse proved to be a very simple matter, thanks to the assistance of an amiable gentleman in the train, who, being asked for assistance, bowed gracefully out of the window at each station and inquired if the train were the right one. It was observable that although the gentleman lifted his hat freely to the porters they did not respond in kind, but gave very scant attention and very brief replies.

We met at the Chemiehalle, some 100 to 120 of us. There was an oration, delivered by a gentleman whose name was not grasped, and then an explanation of the judging arrangements, given by the excellent General Secretary, Dr. Wittmack. These preliminaries were as deliberate and sedate as subsequent proceedings proved to be. Each section was indicated, and then the Judges were told off in sets of three—such an array as speedily put to rest any fears of

overwork. Our first task was to find the classes, and in order to make sure we missed none we went steadily round the whole Exhibition several times over. There was one advantage of this plan, and that is, it enabled the Journal representative to get a good general idea of the character of the Exhibition. He is not going to report it in detail, as that would have no value or interest for British readers, but a few jottings may be of interest as giving an idea of the way in which the Germans grow and show plants.

The comparative fewness of Orchids was noticeable. There were none of the large groups that the early days of the Temple Show gave us. Possibly the number of wealthy Orchid lovers is not so great in Germany as in England. In the first large hall there was a fairly representative collection from Mr. J. C. Schmidt, but the specialities in it were not numerous. *Cypripedium Morganiae*, *C. Harrisianum superbum*, and *C. hirsutissimum* were good, and so were several *Cattleyas*, amongst them *C. Mendeli Souvenir de la Reine*, but they cannot by any stretch of imagination be described as novel in their interest. *Cypripedium Exul* in Mr. Brandt's collection was fresh, and *Mesospinidium vulcanicum* not an everyday affair.

There was a small contribution from England bearing the familiar name of Sander; not all Orchids, however, but the two new *Dracaenas Sanderiana* and *Godseffiana*, *Caladium albanense*, *Cypripedium Rothschildianum*, with a few other novelties.

There was no lack of general flowering plants. Three parts of the *Hydrangea hortensis* were blue, and this would suggest either that the soil of the growers is naturally well stiffened with iron, or that they artificially provide for a special public taste. Amongst the happy ideas in the way of simple grouping was a circle of *Boronia elatior* surrounded by the attractive yellow and white variegated plant *Ophiopogon jaburan aurea variegata*. The *Boronias* were free, loose, profusely flowered plants, about 18 inches high by 12 inches through, and very beautiful the whole arrangement looked. The principal hall was nearly full of *Roses*. There were abundance of pot standards, 4 to 5 feet high, and this type of plant appears to be in strong favour. They can hardly be called handsome, however, and it is a little odd that they can be in such demand as is indicated by the number shown. The bushes were mostly small plants, about 2 feet high, and one German gentleman shrugged his shoulders as he recalled a visit to the Crystal Palace in the days gone by.

Rhododendrons were one of the best features of the Show, and it is clear they are popular in the Fatherland. The varieties, too, are of the best. There was one magnificent trophy of them, 200 feet by 150, arranged on a sloping bank, as naturally as possible, with a waterfall in the centre. It was a triumph, and if we had something of the same sort to show we should think ourselves clever. It was pleasant to see a number of first-rate varieties of English origin amongst the collections of smaller plants. There were specimens by the hundred, about 18 inches high, in 6-inch pots, and they were exceedingly beautiful. Amongst them was the splendid white *Helene Schiffner*; a good carmine, named *Kaiser Wilhelm*; a crimson, called *Bernhard Lauterbach*; a blush, named *Comte de Gomer*; and a splendid crimson, called *L. L. Liebig*. These would strengthen any collection. The German florists are exceedingly strong, too, in *Pelargoniums* of the *Odier* section. Mr. Bürger of Halberstadt exhibited a large number of his own raising, some of which we ought to have. *Meta*, rose, with purple shade, very large; *Lina*, white, with crimson blotch; *Onkel Pitt*, rosy carmine, with dark blotch; *H. Kirchner*, rose, with dark blotch; and *Direktor Zinck*, rosy carmine, are all genuine good things. The raiser named has, it is said, given attention also to *Begonias*, and if he does as well with them as with *Pelargoniums* he is to be known.

Of *Cinerarias*, *Calceolarias*, and *Cyclamens* the following may be said:—The Germans are good with the first, weak with the second, and very strong indeed with the third. They have good strains of *Cyclamens*, and know how to make the best of them. Their plants are large, and throw up pecks of fine flowers well above the leaves. The *Cinerarias* are perhaps hardly so good in type as the best of ours, but they are very little behind, and the plants are very freely flowered. *Calceolarias* are far behind us. As regards general culture with florists' flowers of this class it is very much on a level with that in England. *Lilacs* are a strong point with the Germans. They may not originate, but they can make fine use of existing material. The beautiful semi-double *Michel Buchner*, as also *Léon Simon*, *Perle de Nancy*, and *Madame Lemoine*, were splendidly shown. There were large plants, and small all healthy and very full of bloom.

The fondness of the Germans for standards was evidenced again with the Fuchsias. Three parts of the plants were of that class. The most popular type appears to be a plant on a stem of 2 to 3 feet. We might not call them handsome in this country, our preference being for more natural material in the form of untrained bushes. But they are too well grown to be other than attractive. There is nothing particular to be said about varieties, but it might be remarked in passing that there is at least one thing in common between florists of the two countries. A question as to the meaning of the word "verbessert" drew the reply, "that is improved," and then a fat "ha, ha!" There have been recent jokes, it is said, in the German papers as to the "improvements" of the florists, but we regard that subject as too sacred for mirth. A group of plants of Fuchsia triphylla hybrida, a cross between triphylla and corymbiflora, received a great deal of attention and an honour from the Judges. The plants were only in bud unfortunately, but the foliage is handsome in a quiet reposeful way.

There is nothing to be said about hardy plants generally, which were sparse indeed as compared with our leading shows. The same with bulbs. There were a few Narcissi, but there is perhaps no German Barr or Engleheart; anyway, most of the varieties were old, old friends. Amaryllis (Hippeastrums) were fair rather than great. Ismene (Hymenocallis) calathina was well shown, and it is unquestionably a most useful spring blooming plant. There were giants amongst the Myrtles, of which marvellous examples were shown; but Crotons and Dracenas—indeed, foliage plants generally—were more noteworthy for health and cleanliness than size.

To sum up the main difference between a great German and English exhibition it is grace *versus* solidity. There are no blocks of huge specimen Azaleas such as Mr. Turner and others have exhibited; no fine bushes of Clematis like the noble plants with which Messrs. Richard Smith have delighted us; no large bush Roses like those of Mr. George Paul and others; no stately Caladiums of the type exhibited many times by Messrs. Laing. The vast bulk of the material was "stuff" of the market type, healthy, very freely flowered, admirably grown, but small. It might perhaps be thought that mere market plants would be altogether lost in the huge permanent buildings, each nearly double the size of the Drill Hall and far more lofty; but the Germans are too good artists for that. There was not a pillar but what was draped to a height of 12 feet or so, and the side walls were covered to the same height with a sort of arras, or tapestry of greenery. In the corners and at each end were either groups of Palms or sloping banks of large flowering and foliage plants. There was turf everywhere. The whole of the centre of each large building was covered with it, save where groups of plants stood. The floors, in fact, were turned into lawns, from which circles and triangles were cut, as it were, to admit of the plants.

There was no attempt whatever to keep classes together; on the contrary, there was every endeavour to keep them apart. One or two Judges seemed rather inclined to growl, but the vast majority accepted it in the most philosophic way, marching placidly from one place to another. Sometimes it was a little awkward. Imagine having one group at the Drill Hall, a second at the Hotel Windsor, and a third at the Army and Navy Stores, then you are fairly near getting an idea of the state of affairs. Whether the system is good or bad depends on the point of view taken. An English judge in a hurry would say it was as bad as bad could be; a visitor who simply wanted to admire a spectacle would pronounce it very good indeed. And as shows are presumably arranged less for the benefit of judges in a hurry than for pleasing the public there is perhaps no good ground for criticism.

It is pleasant to be able to vouch for the deliberative care with which German judges do their work. We were allowed a day, and we filled it out somehow. We gave tremendous reflection to everything. Nothing could have been more impressive than the nice adjustment of points. In the writer's section there were about fifteen classes. These were disposed of triumphantly in ten hours. Occasionally, it is true, we had a siesta, but that freshened our reflective faculties, and enabled us to attack our work with renewed energy. There was no indecent haste, no slipshod workmanship. We examined the plants from petal to root. There was something—this is said with all modesty—almost sublime in the profound conscientiousness with which every man of us discharged his judicial functions.

Over all there reigned an infinite good humour. The sense of our responsibilities did not weigh on our spirits as it might have

done under duller skies. There was sunshine on the dancing waters of the adjacent Spree, there was sunshine on the visages and in the hearts of every member of the great jury. The lunch was a festive gathering, not a solid swallowing exhibition. There was endless chatting, but very little speechifying, and that says enough. The most prominent orator was a Court official and distinguished amateur botanist, Mr. St. Paul Illaire, and he was brief and sparkling. Every person present was resolutely determined on two things—to do his duty, and to do it joyously.

HAMBURG.

By a coincidence that starts one "furiously thinking," the chief political and the chief maritime towns of Germany have a celebratory exhibition, not only in the same season, but starting in the same week. Fortunately for judges, writers, and such like, the two centres are sufficiently near each other to be reached by expresses in about four hours, consequently there is no difficulty in getting quickly from one to the other. At a pinch, the two great shows could be done in a day; but it is a pinch that no one with due regard for his own comfort would subject himself to. The Hamburg Exhibition is not a solitary show, lasting a few days only; it is a permanent exhibition, lasting the whole summer, and strengthened by special shows at certain intervals, just as was done at Earl's Court a few years ago. There is a difference, however, between Hamburg and Earl's Court—a difference of some significance, inasmuch as the cost of the affair has been subscribed in advance. There is talk in Hamburg of the Exhibition costing over £100,000, and yet the promoters maintain a cheerful demeanour. Perhaps if it all had to come back again in the shillings of a fickle public there would be less complacency.

To put matters in some preliminary order, the Exhibition is an international one of horticulture and horticultural products, opening on the first day of May, and closing at the end of September. The special shows are (1) May 1st to May 7th, principally for groups, specimen plants, novelties, and miscellaneous exhibits; (2) from May 30th to June 3rd, principally for Pelargoniums, floral work, and early vegetables; (3) July 2nd to 6th, Gloxinias, Roses, trees and shrubs (cut twigs), and floral work; (4) July 30th to August 3rd, tuberous Begonias, Carnations in pots, cut flowers, and fruit trees in pots; (5) plants generally, including groups, specimens, collections, novelties and market plants, floral work, and vegetables; (6) fruit. Thus there is provision for all classes. There will probably be sufficient in the permanent Exhibition to reward a visit at any time; but as visitors from England will naturally prefer to go when there is a special show the hint may be dropped that they are likely to do best for themselves by selecting No. 3 or No. 6.

There are many ways of getting to Hamburg, amongst which are the following:—(1) by Queenborough and Flushing (L. C. and D. Railway in London); (2) by Hook of Holland (Liverpool Street in London); (3) by express to Harwich (from Liverpool Street), and thence by General Steam Navigation Company's boat; (4) by boat direct from Grimsby. By way of variety the present writer tried the Hook of Holland route going, and the Hamburg-Harwich route returning, and was well satisfied with both. The Hook of Holland route means a short sea and a long railway journey; the General Steam Navigation Co.'s route means a good deal of sea and a very small modicum of train. It is largely a matter of taste which is the better. Both ways there is comfort and convenience, and the two companies work in friendly harmony. A horticulturist might enjoy a most pleasant holiday by running over to one or other of the shows. There are special tickets issued, the shows are very fine ones, and the town is full of interest. A sprinkling of visitors from England, more or less familiar in horticultural circles, foregathered at the opening show, amongst them being Mr. Ballantine, Mr. Geo. Gordon, Mr. J. Hudson, Mr. F. Sander and his sons, and Mr. W. P. Wright. One of these gentlemen made the following round, and recommends it to others:—Liverpool Street, Hook of Holland, Haarlem, Amsterdam, Berlin, Hamburg, Harwich, London.

The pleasantest part of the pleasant city of Hamburg is that surrounding the beautiful Alster, and here are situated a series of excellent hotels, such as the Hamburger Hof, Streit's, and the Belvedere, any of which may be chosen. It is a bare ten minutes' walk from any of them to the Exhibition, which is in the Heiligengeist Feld, or in plain English, Holy Ghost Fields. But as the average Briton likes to board something or other, it may be mentioned that he can, if it so please him, enter an electric tram-car, have a penny ride all round the town, and alight at the gates. He will have a novel experience if he does, for the cars are far ahead

of our home ones. The lighting and motor power are both communicated by electricity, the latter in a very ingenious way, from overhead wires. The prejudice against the latter in this country seems baseless. So far as could be judged, no particularly devastating results attend their use in Germany, and the car system is a very complete one, admirably worked.

In now referring to a few features of the show no attempt will be made to give detailed results of the competitions, which would be but poor reading out of Germany. As in the case of Berlin, a general survey will be made. It is too early to speak about the grounds; even the Tulips are not at their best yet, but they will be beautiful by-and-by. The provision for the special show consists of a long range of buildings on the right-hand side of the grounds, terminating in a splendid hall of great size and handsome construction. Altogether, the accommodation is equal to about six Drill Halls. There is not much tabling; the Germans do not appear to believe in that, but there is extensive provision of ground space in flats, mounds, recesses, and banks. The leading idea is spectacular effect. The exhibition is to please and educate the public, but first of all to please them; and the German gardeners are real artists. They group their plants boldly, blend their colours cunningly. They are equal to very striking and vigorous effects; they are also equal to exceedingly quiet and subdued ones, of which more later.

By way of tickling the palate and preparing it for the good things to follow, the first building, the one nearest the main entrance, is given up to groups and blocks of plants, very skilfully arranged. Take one side. There was a central group, oval in shape, of Anthuriums, giving a rich block of colour. To right and left of it were beds of Amaryllis in various colours; outside of these beds of Carnations, different sorts, the whole flanked by a beautiful bank of Primula Sieboldi. In every case the plants were in pots plunged to the rims. The Primulas came from Messrs. Goos and Koenemann, and were a splendid collection, embracing many beautiful sorts, but there was a slight confusion of nomenclature, which a knowledge of English would have averted. For example, a block of a fine white was cheerfully disguised under the name of Ruby Queen. Mrs. Ryder, Peach Blossom, Miss Nellie Barnard, Maiden's Blush, and Arthur were all very conspicuous amongst the varieties. The same building contained two other exceedingly attractive features—namely, fine groups of Roses and Lilacs, also plunged. The Lilacs were particularly fine, and we do not often see them like it in England. There were large bushes, small bushes, and standards, all full of bloom, the sorts including such excellent ones as Charles X., Madame Lemoine, Léon Simon, and Michel Buchner. They came from Mr. Harms of Hamburg.

As at Berlin, there were beautiful collections of dwarf pot Rhododendrons, the plants about a foot high and through, and full of bloom. Many people would regard these as even more attractive than the quarter specimen Azaleas which are so popular. There is a great range of colour amongst them, and they are in every way pleasing and effective. In one of the groups in this building were some beautiful objects in the form of Prunus triloba, in 6 and 7-inch pots, the plants from 1 to 2 feet high, and smothered in their soft pink flowers. A charming effect had been produced in one part by plunging a collection of the lovely little Saintpaulia ionantha, which with its soft heart-shaped leaves and violet flowers presented as pretty a picture in the turf as a clump of Violets in an English hedgerow.

The Orchid section was entirely dominated by a contribution from Baron Schröder. There is no wish to disparage the other exhibits, several of which were good, and all admirably arranged; but in horticultural interest the Baron's group was paramount. It contained a large number of good and interesting things, amongst them being Luddemannia Lehmanni; Cattleyas speciosissima and Parthenia; Lælia Latona; Cypripedium bellatulum album, Gertrude Hoffington (this striking chocolate flower was a cynosure), Clonius, Mastersianum, Rothschildianum, nitidissimum, and Dayanum; Odontoglossum crispum Rex, Wilckeanum, Queen Empress, and Cervantesi roseum; Maxillaria Sanderiana; Lælio-Cattleya Marriottiana; Vanda Gottschalckei, and Masdevallia Benedicti. It was very appropriate that so splendid an exhibit should come from a distinguished Anglo-German like the Baron. Messrs. Sander had a mixed group, chiefly composed of Orchids and new plants. In the centre was a glass case, enshrining a treasure in the form of the ruby Cypripedium Oakes Ames (Rothschildianum × ciliare). Amongst other plants were Cattleya Schröderæ and C. S. cœrulescens, Asparagus albanensis, Cyrtanthus obliquus major, Calla Elliottiana, Araucaria excelsa (Sander's variety), Sander's

Variegated Canna, Dracænas Godseffiana and Sanderiana, Caladium albanense, Renanthera Imschootiana, Licuala grandis, and Heliconia illustris rubricaulis. Special honours were awarded.

France had a notable contribution in the shape of a group of Nidulariums and Vriesias, which came from the nursery of Messrs. Duval et Fils, Versailles. They comprised Nidulariums rutilans and striatum, Vriesias Eros, fenestralis, splendens, Kittchiana, Duvali major, Duereti, and Manoti. They were all in flower, and made a very singular, interesting, and attractive group. Mr. Theodore Reimers also had a collection of much interest, comprising a number of Bertolonias, Nidulariums, Erechtocnema Sanderiana, and a magnificent specimen of Medinilla magnifica. Mr. F. A. Haage, jun., of Erfurt sent a large number of Cactuses in thumb pots, which would arouse admiration from specialists if not from the general public. The one notable fruit exhibit came from France (M. Nohle). It was composed of splendid Peaches, Cherries, Strawberries, and Raspberries. The jury rightly gave a special prize.

More might be said about various exhibits, but having by this time found his way into the great hall, the writer found so much to admire that small matters were passed. Imagine an Albert Hall-like building, of immense height, supported by lofty pillars, and of the most ornate construction. Imagine the interior to consist of an orchestral-like elevation at each end, a long, broad terrace on each side, and a central floor surrounding a small lake, fed by winding streams. Finish by imagining the whole place packed with plants, not lumped together, but disposed in the most artistic way, and you have a faint idea of what cannot possibly be described. The whole thing was a work of supreme art, of plant and flower grouping on the most magnificent scale. There was a general effect which struck every visitor with the liveliest admiration, and there were numerous individual effects of the most beautiful nature.

The raised ground at the upper end was covered with groups of Clivias and Hydrangeas, flanked by Palms and Tree Ferns. Sloping from it to the floor level was a huge bank of Azaleas and Rhododendrons, all fine specimen plants, densely flowered. These were arranged in blocks of colour. In a sunny recess amongst rocks, on which the sun fell obliquely, was a glistening group of Azalea mollis, and beneath a large skylight, through which a softened light fell, was a semicircular group of Lilacs, Gueldres Roses, and Prunus triloba. This was the triumph of the whole exhibition. The white and lavender tints of the Lilacs, the greenish white of the Viburnum, and the soft flesh pink of the Prunus blended in the most chaste and delicate way. In other parts of the hall were huge groups of flowering and foliage plants. On the ground floor an area of perhaps 200 feet by 150 was given up to groups of different plants, surrounding the water already referred to, and which was dotted with Arums. There were groups of Cinerarias, of Azaleas, of Clivias, of Oranges, of Gloxinias, of Anthuriums, of Hyacinths, of Vriesias, of Roses, of Camellias, of Genistas, of Dracæna Lindenii, and of Maidenhair Ferns, and in one corner was a block of Lilies of the Valley, snugly shaded by the leafage of huge Palms. At every turn some new feature met the eye. In short it was, as before said, a triumph.

Amongst the numerous officials conspicuous good work was done by Prof. Zacharias (the general Superintendent), Herr Jürgens, Dr. Herz (the foreign Secretary), Herr Siebert of Frankfurt, and Herr Lauche of Eisgrub, Austria. There was the usual opening ceremony, which took place on the morning of May 1st, and the usual banquet, which was held on the Monday evening, May 3rd. The *Journal* representative boarded the swift *Peregrine* en route for England before the festivities began, but he carried away an impression that the Germans had set themselves a great task in this exhibition, and that they had risen to the occasion like men.

A SIMPLE INDOOR ADORNMENT.—Recently a fine example of what can be done in the way of indoor decoration by a simple arrangement came under my notice, and as anybody can adopt the expedient in an ordinary sitting room, a few observations may be interesting to some readers. About two years ago a seed of the common Horse Chestnut was inserted in a pot along with an established plant of Asparagus tenuissimus, and the result is now a stately little tree, rising above its more aristocratic companion. The combination perhaps is not quite harmonious, but nevertheless is pleasing and suggestive. The Chestnut was picked from a noble tree growing at Versailles—a name which carries the memory back to war's alarms and devastation, and the overthrow of Imperial France. If trees could see and speak, as well as "think," like Mr. Thomson's Vine, what a story the parent of this sprightly and ambitious little foreigner could tell!—J. M.

THE SCHOOL GARDEN.

EVERY country school should have its adjacent garden, to be cultivated by the boys themselves, under proper supervision. It should be regarded as an indispensable aid to technical instruction in the village; and not only this, it would be an instrument of education of great value and importance. At best the school life of the farm labourer's son is but of brief duration; therefore the time at disposal ought to be utilised to the best advantage, and, as much as possible, having direct bearing on the child's future prospects. This we know quite well is not the case with regard to village schools in the United Kingdom.

As usual we are forestalled by several of the most powerful of our neighbours on the Continent. Switzerland is to the fore; there are training colleges for the preparation and equipment of teachers for the schools of the Canton. At one of these colleges, near Lake Constance, there is a large farm cultivated by the students under skilled instructors. The farm has orchards allotted to it, and there they learn on the land itself, not merely in the lecture room, the science of farming and gardening. The students in the Swiss college are prepared for the mastership of rural schools, where they will associate with the peasant farmers and teach their children.

France has for many years had school gardens; Germany years ago saw the necessity of such instruction, and provided for it liberally; Sweden has over 2000 school gardens, and so long ago as May, 1869, the Austrian Public School Law says:—"In every school a gymnastic ground, a garden for the teacher, and a place for the encouragement of agricultural experiments are to be created." "And to see that in the country schools school gardens shall be provided for corresponding agricultural instruction in all that relates to the soil, and that the teacher shall make himself skilful in such instruction." Moreover, "Instruction in natural history is indispensable to suitably established school gardens."

One can imagine, after thinking over these wise provisions, what an immense impetus to gardening and allotment cultivation would have been given had our Education Department followed such an example. That "per-centage machine" of Mr. Robert Lowe resulted in causing a quarter of a century's delay in the progress of education.

Forty years ago there were gardens for the use and instruction of boys attending country schools in England. Those of Lords Hatherton, Lyttleton, and Ellesmere, with the schools of Finchley and Highgate, were highly commended by Her Majesty's Inspectors. There were Government grants in support of this teaching. For various reasons, however, the schools failed to secure the sympathy and co-operation of the parents. One can scarcely wonder at this. The labour was, in a way, compulsory, in some instances excessive, and in few cases did any systematic teaching accompany it. The system was entirely wrong. Sometimes a small remuneration was provided—perhaps a halfpenny an hour; rent was charged, and payment for the use of implements. Moreover, the work was done in common, similar to that of the industrial and workhouse school, and it lacked the feeling of responsibility and ownership of produce which alone gives zest and interest to the employment.

Perhaps, however, Mr. Lowe's scheme of "payment for results" had most to do with the gradual failure of school gardens. Where a considerable portion of the teacher's salary depended upon the per-centage of so-called "passes," not only his income was in peril, but his credit and situation were at stake, and so interest in the "school garden" rapidly declined.

It is a gratifying circumstance that the common sense of the rural districts is now aroused, and County Councils almost all over the country, as initiated in Surrey, are encouraging technical instruction in gardening, also elementary agriculture. Having some knowledge of the subject from both sides, I will venture to submit a word of warning. For years the South Kensington Department have been preparing—save the mark—and sending forth so-called "lecturers" on "elementary agriculture," many of them assistant masters in Board and Voluntary schools. After listening to a course of lectures and reading certain text books they have, from a paper examination, gained a certificate and forthwith began lectures themselves, and earned "Government grants" thereon. Some of these persons I have known, and doubtless there are many others, who had no practical knowledge whatever of the subjects they professed to teach. Books, if good, are useful; and lecturers, if taught in the school of practice, may do good service, but without actual teaching on the soil itself, under competent supervision, the results may be next to worthless.

And now I revert for a moment to the reports of some of the ablest of H.M.'s School Inspectors. "The practical knowledge acquired," said the Rev. F. Watkins, "by these young gardeners will be useful and interesting to them in whatever situation they may be placed. The cultivation and refinement of their tastes by more observant acquaintance with the wonderful and beautiful

works of Nature, and above all the healthy and cheerful occupation of time, will by God's blessing save them from many a temptation and many a trial in their after life. I believe it is hardly possible to overrate the moral or economical value of school gardens in manufacturing quite as much as rural districts of our country." I venture to quote a second extract from another of H.M.'s most experienced inspectors, The Rev. J. D. Stewart—"Occupation in gardening teaches the use of common tools and implements; it affords unlimited scope for collateral information, and makes working men handy and fertile in resources; also puts within their reach the means of adding to the comfort and decency of everyday life in their homes. The wider issues with which this branch of education connects itself—the preparation of future colonists—is of obvious importance."

This subject of school gardens, owing to the rapid extension of the allotment system and peasant proprietorship, is of growing importance. An essential consideration, however, seems to have been entirely overlooked. It appears to be taken for granted that the farm labourer's son may dispense entirely with such technical instruction in his calling as is considered essential in most other callings, in which both hand and head are concerned; and that the lad acquires sufficient knowledge of the implements and materials of the garden or farm, and the several operations pertaining to the tillage of the soil from the mere circumstance of having been brought up on the land, and set to work on it from his early boyhood.

School gardening, under a sensible *régime* and systematically cultivated, also by men who know the actual value of the work and crops, has a high mission—that of lifting elementary education to a higher level, of keeping many of the best labourers on the land, of improving the social condition of rural communities, of adding materially to the food supply of the country, of investing the farm labourer's work with greater interest and significance, thereby enabling him to increase his income, and add to the comfort and attractiveness of his home.

It is not for a moment assumed that "scientific agriculture," or even much gardening can be taught on a few poles of land, under the instruction and guidance of a schoolmaster. It is not impossible, however, as the writer well knows, to awaken an intelligent interest in the matter, to show how much can be done towards convincing the young labourer of the latent energies of the soil that may be called into action by skilful cultivation, to call out the powers of intelligent observation and reflection, and to implant such a love for and appreciation of the Book of Nature as shall be of inestimable value to him in after life, and invest his ordinary occupation with fresh importance and a new and abiding interest.—HERGA.

RHODODENDRONS.

IF a census were taken of the most popular hardy evergreen shrubs it is more than probable that Rhododendrons would come out very nearly at the top, for they are beautiful alike both in and out of flower. When in full beauty they are unsurpassed by any flowering evergreen, and when out of flower their shapeliness and bright green foliage render them fitting specimens for lawns or for massing in beds. They are at home in any position, whether in the neighbourhood of a town or in the pure air of the country. Under trees or in the open, in sheltered nooks or in exposed situations they are alike suitable, and thrive if their simple requirements are attended to. They, however, do not like soils in which lime and chalk prevail, and in such instances special preparations must be made for them. They are worthy of all this, and of much more care than is bestowed on them in many gardens.

Rhododendrons will grow under forest trees, but ought to be planted at the same time, for after trees become large and the soil crammed with roots there is great difficulty in establishing them. Before they have a chance of taking possession of the soil by their roots they suffer from drought, and often die the season after planting. If the growing trees have been well thinned, and large stations are prepared by digging as deeply as the soil will allow, incorporating with it leaf mould, manure, loam, or even the refuse of the potting shed, or a quantity of the whole mixed together before planting, success can be insured, especially if the shrubs are well watered for the first season until the roots have got well hold of the soil. In the front of plantations of forest trees there is less difficulty in establishing them. When once well rooted in woods and plantations in which the leaves of deciduous trees are allowed to remain, they will need little attention. When both are planted together and the trees duly thinned they grow rapidly if the soil is of a fertile nature or rendered so by preparation. For undergrowth, as well as for the margins of woodland walks and drives, no plant equals *R. ponticum* in my opinion.

In whatever position they may be planted it is a great mistake

to prepare a small hole and render the soil immediately surrounding the roots fertile to give them a start. Under this treatment the plants grow well for a few years only, until the prepared soil fails to supply them with the requisite amount of food. They decrease in health and vigour in proportion as the soil beyond the station made for them is rich or poor. In naturally fertile soils they flourish without further trouble, but in the majority they become thin and bare, while in others they linger between life and death, only to succumb the first time their energies are severely taxed by a long spell of drought, cutting winds, or severe frost. They frequently succeed better in woods when left to Nature for their supply of food than they do in borders or dressed portions of the pleasure grounds. It is in these positions that Rhododendrons, instead of growing luxuriantly, become bare from exhaustion. Every particle of material that would provide them with food is brushed away for the sake of appearance. This would not be objected to if the shrubs were supplied with sustenance to withstand the adverse circumstances to which they are often subjected.

I have seen these shrubs grow with wonderful vigour in 6 inches depth of heavy soil resting on a bed of clay, and equally well in light sandy soils, also on peaty grounds when left to Nature. In each instance, as is natural to the Rhododendron, they rooted closely beneath the surface, and their own leaves, and those that were drifted under them, soon induced a mass of fibres, and the fallen leaves protected the fine hair-like roots from destruction by drought. In gardens their food is removed, and annually numbers of the surface roots are cut off by the too general practice of digging amongst them. In summer they suffer by drought, and with such treatment it is no wonder they look thin, poor, and unsightly.

To insure success digging must never be done about the roots; it is only to give a neat appearance, and to prevent leaves that have drifted in from being blown out and carried on to the lawn or surrounding places. This is to save labour, which can be accomplished by another method, if not quite so quickly, with benefit to the shrubs. The loose leaves can be brushed or raked out unless the necessary material is at hand for top-dressing them as the work of cleaning proceeds. Refuse from the garden, such as leaves, the mowings of lawns, and the edgings of walks, make capital material for top-dressing. The refuse from the potting shed, the surface soil removed from vineries, or Peach houses—in fact, all soils after they are useless for indoor work—are excellent for the purpose. Often old hotbeds are available, and a few loads of soil after the most fibry portion has been removed for potting purposes can be purchased in the neighbourhood of towns for covering leaves or material that might blow about.

In large gardens the quantity of refuse from the various departments amounts to a large heap in twelve months, which if thrown together and turned will be found ample for top-dressing many clumps and single specimens of Rhododendrons. They root freely into leaves or garden refuse, which generally consists of a quantity of rich fertilising material. On light soils I prefer a dressing of cow manure with a thin sprinkling of soil on the surface, because it retains moisture much longer than other refuse.

The best time for top-dressing is during the winter or early spring, while the roots are moist, as then the material applied will keep them in that condition throughout the summer. Instead of the shrubs being injured, as is usual during dry weather by the destruction of the surface roots, it will be found on examination that the old top layer of mould is a mass of white fibres that are taking possession of the new soil. If the top-dressing is about 4 inches thick it will last at least three years before it need be repeated.

Not only do Rhododendrons grow with greater vigour and retain a fine, dark, glossy appearance by top-dressing periodically, but they brave cutting winds in exposed situations without in many cases receiving the slightest injury. In exceptional cases if they are browned they quickly recover before the season is over. Plants in poor soil subjected to the evil conditions pointed out are certain to be cut very much, and seldom recover; in fact they always present a thin, naked appearance.

It is not wise to cut back Rhododendrons that are in an exhausted condition. They should be allowed to grow one season after top-dressing, and then may be cut back during the early spring months. It is a mistake to delay pruning them until they have flowered, for they are then late before they start their growth, which is not well ripened before the winter, and in severe weather the shoots are often killed. With plants in a partially exhausted condition the flowers must be removed directly they fade, and not be allowed to remain and ripen their seeds. This is necessary in any case, both for appearance and the well being of the shrubs.

Planting in exposed positions should be done during September. In sheltered places Rhododendrons may be planted at almost any season of the year, provided the soil is moist; if not, considerable labour is occasioned in watering.—A. N.

ODONTOGLOSSUM CRISPUM LUCIANI.

THE additions to this beautiful class of Orchids continue fairly numerous, coming from all sources, and there are now scores of varieties to which distinctive names have been attached that have been honoured by the Royal Horticultural Society. One of the latest is O. c. Luciani, of which we give an illustration (fig. 78). This was shown at the Drill Hall on March 23rd by Mons. Lucien Linden, and received a first-class certificate. The form of the

FIG. 78.—ODONTOGLOSSUM CRISPUM LUCIANI.

flower is superb, while the substance is splendid. The ground colour is white suffused with rose, with abundance of large chocolate blotches.

INSECT INVASION.

"I WANT to know what really *will* kill insects? My garden is invaded every year, do what I will. Can you give a good article to help me in my difficulty?" Such is the appeal of a correspondent who seems to write almost in tones of despair. The invasion we suspect is the natural cause of repressive measures not being taken soon enough. Let our friend read and digest the following injunctions:—

Gardeners and cultivators of plants, trees, and crops generally have many enemies to combat. Watch must ever be kept to prevent some of them stealing a march and taking a firm position from which they cannot be dislodged without injury to the possessions on which they have seized. Insects of various forms start into life with the same regularity that leaves unfold in the spring, and those insects fight for existence with a determination that often leaves them victors.

The increase of insects leads to the ruin of plants and crops, disquietude of minds, and the emptying of purses. The waste is enormous, and if it were possible to estimate the amount of damage done, with the outlay incurred in the general warfare against the enemy, it would be startling in its immensity. Undoubtedly one of the most important duties of the gardener is to mitigate, so far as it lies in his power to do so, the great evil wrought through insect agency, and it is certainly in the interest of owners of gardens to give all the assistance they can in the furtherance of that object.

There is no greater mistake made in gardening, and unfortunately few more common, than to lightly ignore the presence of one or two insects. It is no more safe or prudent to do so than to pay small regard to the outbreak of a fire in a warehouse of valuable combustibles. The first spark, if seen, may be stamped out

easily, but hesitation is fatal. It is the same in respect to insects. Let the first arrivals remain undisturbed, on the ground that such a few cannot do much harm, and it is "not worth while wasting tobacco or other insecticides on them," and injury if not ruin to the plants or crops will be inevitable. The greatest calamities have followed from underrating the strength of the enemy, and permitting the aggregation of units, till they grow into a mighty force. This is precisely what is done and permitted yearly in greenhouses and gardens all over the land. The first few aphides are weak and easily subdued, but allow them a few days' freedom, and they will entrench themselves so firmly and increase with such rapidity as to become a formidable foe.

To allow insects to multiply into a devastating swarm is both costly and cruel. Costly because the deplorable results in half-formed Vines, fruit trees and plants represent a great waste of wealth; and because a far greater outlay must be incurred in insecticides and labour in applying them to prevent total ruin, that originally would have insured a remunerative return in the realisation of healthy plants and profitable crops. It is cruel to even passively encourage the increase of insects, and then, as must be the case, engage day by day in the miserable work of carnage, for it cannot be otherwise designated. It is cruel to the plants and trees also, in having their life blood drained away by the enemy that has been suffered to infest them, and which might have been prevented if the requisite means were provided and promptly applied. The owners of gardens are responsible for providing the means, the managers for their application.

Insects have often gained the mastery over gardeners through the mistaken policy of waiting till the plants and trees have been seriously infested before even "ordering" insecticides for their extirpation. Such delay on the part of those owners of gardens who personally order what is needed is a serious mistake; in the case of gardeners who can supply themselves with every requisite it is inexcusable. A shilling spent in insecticides early in the season, and the powder or solution applied when the first insect is seen, or, what is better, before, as a preventive, will effect the desired purpose far better than can be accomplished by an expenditure of 20s. after the shoots of trees and plants are crowded with aphides, which, further, by puncturing the leaves, cause them to curl over and effectually protect the enemy that is depriving them of life.

The rapidity with which plant lice multiply is marvellous, and perhaps not sufficiently recognised. According to the calculations of one great scientist five generations proceeding from one mother produced 5,904,900,000 in a season. It is true there are natural enemies for checking the increase, as ladybirds and ichneumon flies, in nature, but they are rarely present, and never in sufficient numbers early in the year where cultivation is practised to a large extent under artificial conditions. The natural enemies of insects must never be relied on for destroying the latter, but other agencies should be resorted to for preventing the appearance of the pests, or at least be applied with promptitude directly the first insect is seen.

Waiting till the young growths of trees and plants are much infested with insects before applying remedies is placing the latter at a great disadvantage, and is often unjust to the manufacturers of insect-destroying compounds. Used in time, a moderate strength suffices for the extirpation of plant pests, and leaves the plants unharmed; but when the insects cluster on each other in layers, and so affix themselves as to make their prey their shelter, much stronger and repeated applications are called for; and as these cannot destroy the insects they do not reach, and the exhausted foliage cannot withstand the strong applications, what has been applied is not only pronounced useless but dangerous. Nothing can be more unfair. The fault is too near home to be admitted perhaps, but it is there nevertheless, and not with the insecticides, for if those that have been found safe and effectual by experienced cultivators, are used in strict accordance with the maker's instructions, and especially used in good time, before insects abound, they will answer the purpose for which they were intended. This latter condition is of far greater importance than the choice of any particular preparation. Some persons find one kind answer their purpose, some another; and it is a question if there is one in the market that is not safe and good when fairly applied.

Greenhouse plants innumerable; Calceolarias, Cinerarias, Pelargoniums, and others; also Roses in and out of doors; Peaches and other trees on walls and under glass; Vines, Cucumbers, and Melons, are crippled in growth, seriously injured, and not infrequently completely spoiled by aphides, thrips, or scale in their several forms that might with ease be kept clean. The path of safety lies in preventing the appearance of insects. Waiting for their multiplication in myriads before attacking them amounts to giving the victory to the enemy.—W.

PRECEPT AND PRACTICE.

(Continued from page 309.)

PICTURESQUE GARDENING.

WHILST not requiring any great feats of engineering there is ample scope for pleasing expressions of taste with utility in the greater freedom afforded to the head, hand, and eye in path designing. That there should be no crude union visible with the classical outline of formal design and picturesque freedom is evident. Good taste will discover the happy *via media* to insert the necessary semi-tones into our harmony. Its extent may, according to circumstances, be anything from a few yards to a mile in length, but it is in any case the connecting link, requiring more care in fashioning than will ever be apparent afterwards if the junction is smoothly effected. Granted that such is the case there is no startling contrast to court criticism, as our path carries us into the kingdom of picturesque gardening.

Wild or semi-wild gardening, pregnant with possibilities, is, I believe, capable of redeeming the character of the gardener, in some measure impugned by long confinement under the manacled fashion of formality. The latter we will not condemn if the former is not ignored. It has, in fact, as I have previously endeavoured to show, a distinct right of being; but practically excluded as many have been from liberty in this direction, it is not a matter for surprise to find a certain amount of stiffness cramping the hand and clinging to ideas born of more despotic influences.

This phase of gardening is, I think we may justly say, but in its infancy, notwithstanding some evidence to be found of our forefathers' acquaintance with it and those excellent examples under development, but there are sound and sufficient reasons for the inference that it will be of rapid growth, and form the most pleasing feature of gardening in the future.

Returning to our path, which is probably the simplest example of that subject, we need never lose sight of its primary purpose—viz., that however unobtrusive it may be, it is for use in all seasons, and practically for all weathers. It now brings us to a complex state of things, satisfactory and unsatisfactory, farther reaching, indeed, than this phase of our subject. One instance of a common error will convey the meaning, and one is vividly presented to me probably owing to its being in one way the most charming walk I have seen. Evergreens, flowering shrubs, with occasional specimens of our most handsome Coniferæ, might have afforded interest and beauty at every turn; but, alas! that fatal error of crowding, with constant mutilation to keep the path open, spoiled the picture. The direct source of such mistakes is, I believe, an insatiable desire for instantaneous effect. It is pawning the future to supply the present, and although the knowledge of such things must be patent to the veriest tyro in planting, the wisdom of acting upon it is ignored. Such at least appears to be the case when this near-sighted policy is in so many places persistently pursued.

We do not, unless we wish to return to the old Dutch style of gardening, desire to walk between evergreen walls. Dutch gardening is handsome in its way, but there is no mongrel connection between it and our subject to bear the burden of our sins when flowering shrubs, trees, or specimen evergreens are shorn of their characteristic features. The question might here be opened up of rectifying these errors, which in some instances, and under some circumstances, it is, of course, possible to do, but I would rather impress upon embryo planters the desirability of avoiding them.

What possibilities are now opening up for semi-wild gardening, this most pleasing of all gardening delights. Here we want the broadest idea, the freest of free lines. As our path carries us from peep to peep there is something to satisfy, to soothe, or to excite at every turn. Sheltered nooks, where a thousand Daffodils nod in the March winds; deep bays, where a dozen of Berberis Darwini, shrubby Spiræas, or countless things of beauty of form, or flower, or foliage, may be effectively represented. Endless variety, boundless freedom, yet all subordinate to an intelligent design—a design rather felt than seen. Failing this we are like those "whose incoherent style, like sick men's dreams, varies all shapes, and mixes all extremes." Even in those places where this subject has, one may say, been but approached; so many opportunities are created by the initial stage for its development, and one may wander for so many hours with the limit of as many acres feeling that the pleasures of gardening are infinite, its teachings endless, and its works always capable of extension in this direction as time and circumstances permit.

Nature is modest—for our purpose, modest to a fault—often hiding some charming features under the veil of indigenous vegetation. I have seen some beautiful bits of natural rockwork revealed by a little labour in clearing away the rank growth of Nettles, Brambles, and other savage wildlings; and in some places the removal of a few inches of surface soil has been the means to

the end. All such things pave the way to introduce suitable Alpine flora, not to again hide but to adorn. Take, for instance, that unsightly object, a disused quarry, not rarely used as a receptacle for rubbish. Some that I have seen, if transformed according to their capability, would fill a number of the *Journal* in detailing their history.

No hard and fast lines can be laid down to guide young students in the kingdom of picturesque gardening. Every spot, sphere, or locality where the gardener rules (or serves) has its individual character, and requires its own special study and adaptive elaboration, which in many cases will be more happily expounded by manifesting Nature than by reconstruction. Indeed, where the latter is felt to be the sole predominating influence over a gardener's mind it will often be, as it often is, an impassable barrier to his advancing in this direction.

Young men will find, as I have found, that ambitious schemes, generally involving considerable expense of force, material, and money, are received with distrust and suspicion, although this might be reversed if emanating from an eminent landscape gardener. We cannot afford in our desire for freedom to run full tilt at the barrier, but proceeding in a gently insinuating manner we may win our way into the kingdom of picturesque gardening even by such simple measures as the offering of a few bulbs, spare hardy plants, or what not. Now is the time to sow the seeds of observation over the whole ground of the subject, and doubt not but that such fruits will be ultimately reaped, that you will then endorse the opinion I have formed relative to some grievances concerning it—viz., "Our remedies oft in ourselves do lie which we ascribe to Heaven."—AN OLD BOY.

(To be continued.)

CULTURE OF ACHIMENES.

FLOWERS "all the year round" must be provided in greenhouses and conservatories, or the structures fail in the purpose for which they were erected. Perhaps the spring and early summer, or from the present time till July, is the period when such structures are in their zenith of beauty; for besides forced flowers, some of the finest genera of plants are in "fullest natural beauty" at the season named. But these families of plants—Cyclamens, Cinerarias, Calceolarias, and Pelargoniums—must have their successors, and the more distinct these are in habit and colour from the flowers blooming in the open air the more effective will they be when arranged in the houses.

Achimenes are thoroughly dissimilar from all outdoor-flowering plants in habit and the majority also in the colours of the flowers. The plants are, farther, of easy culture, provided they can, especially in the early stages of growth, be afforded artificial heat. Many valuable additions have recently been made to this handsome genus of plants, and no garden of importance can be considered completely furnished with summer decorative plants which does not contain a collection of Achimenes.

Where tubers are plentiful the work of producing fine pots, pans, or baskets of Achimenes is comparatively easy, for the tubers can be planted sufficiently close together that without any, or very little, stopping of the plants fine masses of growth and flowers can be obtained; but where tubers are scarce, as, for instance, in purchasing new sorts, greater cultural care is required to produce plants of an effective size the first season. Yet with even a limited number of tubers good plants may be perfected, as I will proceed to show.

Some years ago I ordered two dozen pots of Achimenes, which arrived during the first week of May. They were in 3-inch pots, each pot containing three plants about half an inch high. With this small beginning I determined to make as good an ending as possible, but did not anticipate the large results that followed. The tiny plants were growing in peat, and were placed on a shelf in the Cucumber house. They were carefully watered and syringed, and were slightly shaded in bright weather. When 3 inches high their points were taken out, and shortly, instead of having three shoots in each pot, I had in the case of some sorts six, and in others nine shoots. When these had pushed half an inch the plants were transferred into 5-inch pots in a mixture of two-thirds of peat and one-third of old Mushroom-bed manure, with a free admixture of sand and lumps of charcoal. After becoming established in these pots the plants were again stopped, and the shoots increased in number from fifteen to twenty-seven in each pot, according to the sorts, some breaking three eyes and others two. The plants with careful attention grew rapidly and were pinched a third time, and some of them produced as many as a hundred shoots. These were trained thinly out from the first, so that each grew sturdily. The plants were eventually shifted into 8-inch pots, and were afforded a compost of loam, leaf mould, old Mushroom-bed manure, and bruised charcoal in equal parts.

By the end of June the plants were too large for the shelf in the Cucumber house, and were moved to cold frames—that is, to frames having no artificial heat. A "cold" frame at that period is, however, really a warm stove if carefully ventilated and the sun heat conserved. On chilly nights the glass was covered for a time, and ventilation was as carefully attended to as for a house of Vines or Melons in early spring. The plants were regularly sprinkled, also slightly shaded and kept as

close as possible, provided the temperature did not exceed 85°. The ashes on which the pots were placed were also kept moist, and especially in the daytime when the sun was powerful. The frames were closed early each afternoon. Under this warm-frame treatment the growth was more vigorous than in the Cucumber house, and some of the plants were 3½ feet in diameter in the autumn, and almost complete balls of flowers, the weaker-growing kinds being proportionately small, yet equally satisfactory. They were greatly admired by all who saw them, and few could believe that from three tiny tubers potted in spring such rich masses of fine flowers could be produced in the autumn.

The secret of my success in growing these plants may be expressed in two words—unremitting attention. I have grown Achimenes for twenty seasons, and have had unlimited supplies of tubers, but I have never had such fine masses as from the first small beginning alluded to. Tubers, soil, means, conveniences cannot compensate for anxious, solicitous personal care in the cultivation of these or any other family of plants. Those cultivators who succeed the best do not simply give orders and leave someone else to attend to the plants; and it was by simply working harder, paying closer and more thoughtful attention than usual to my small but precious stock of Achimenes, that they increased to such large dimensions.

When an article is plentiful it appears to lose value, and does not receive that care to which its intrinsic merits entitle it. When we have plenty of Achimenes tubers we are apt to "take things easy," feeling a sort of self-satisfied consciousness that "that crop is at any rate safe." But we forget that it is on us as the cultivators, and not on the numbers of the plants, that success depends. We have plenty of tubers and we use them freely, sowing them almost like sowing seeds. We know that Achimenes start well in peat, therefore peat is used; but although the plants start well in peat they do not always finish well in it, and hence it is that failures are common when tubers are plentiful—they are lavishly placed in soil that lacks sustaining power; twenty plants are perhaps raised in a pot that does not contain food for half the number, and a good beginning results in a bad ending. Achimenes, like most other plants having fine, hair-like roots, start well in peat; but when a large number of plants is placed in one pot—and the plan is an excellent one—the peat alone will not sustain them throughout their period of growth, and beneath the peat should be placed richer soil.

In potting the tubers when they are plentiful a mistake is often made in filling the pots too full of soil. That is a very simple matter, but is, nevertheless, the cause of many, if not of most, failures in plant culture. A first-class plant grower never makes a mistake of that kind. He provides his plants with soil, and also provides the means of keeping that soil replenished with food for his plants, and this cannot be done when the pots are filled too full. Before plants can have a sufficiency of food in a liquid state space must be afforded to hold the liquid. Achimenes when in free growth require much water, and frequently need more than they receive, simply because an inadequate amount of water-holding space is provided at the surface of the pots. Therefore when many tubers are potted in one, and possibly the flowering pot, let the drainage be ample, the soil rich and rough at the bottom, the surface light, and the pots not filled—if large, to within 2 inches of their rims. If that plan is adopted too many tubers will not spoil the plants; but if it is not adopted—if the pots are filled quite full of light soil only, then the plants cannot receive the support which they need, and plenty (as is too commonly the case) ends in comparative failure.

Besides being adapted for cultivation in pots of various sizes, Achimenes are amongst the finest of basket plants. Baskets lined with moss and filled with suitable soil may be planted with tubers, and if the baskets are placed in a proper temperature and are carefully watered they will in a few months be balls of flowers. White, mauve, and pink varieties, planted in mixture, have a charming effect.—G.

CONFUSION IN CONIFERS.

MR. WEBSTER (page 368) has been exceptionally fortunate if he has frequently secured *C. nootkatensis* for *C. Lawsoniana*, as plants of the former cost about five times as much as those of the latter, and the difference in the price of seed is even greater. The two plants are quite dissimilar when they reach the size at which their characteristics are developed. The main branches of *C. Lawsoniana* droop from the trunk of the tree, and the secondary laterals bearing the foliage are set horizontally to the main branch. In *C. nootkatensis* the main branches rise from the stem curving upwards, and the laterals hang down from them. A well grown specimen is one of the most beautiful of the introduced Coniferae.

The cones of *C. Lawsoniana* form and mature in one season, while those of *C. nootkatensis* only ripen the second year.

In my experience its seed has also generally taken two years to germinate, while that of *Lawson's Cypress* comes away freely the first year, and the plants were of much more rapid growth than those of the other.

C. nootkatensis in its native habitat in British Columbia does not attain the dimensions which *C. Lawsoniana* does further south, but it is a tree of great economic value, growing from 30 to 38 metres in height, with a trunk of from 1.20 to 1.80 metres in diameter, and it is esteemed the most valuable timber tree in Alaska. In this country it flourishes in the poorest soil, and is extremely hardy. No frost affects its colour, but it sometimes suffers from lengthened drought in summer.—K. S. M., Ross-shire.

"JOURNAL OF HORTICULTURE" EDITORIAL DEPARTMENT.—

From the present date, and until further notice, it is particularly requested that all letters and parcels intended for the Editor, also all communications for insertion in the *Journal of Horticulture*, be addressed to S, Rose Hill Road, Wandsworth, London, S.W. N.B.—Business letters and advertisements must be addressed to the City Office.

— WEATHER IN LONDON.—The latter half of last week brought with it a considerable amount of rain, which fell in heavy showers at irregular intervals. With Sunday there came a pleasant change, for though the wind was still cold the sun shone brilliantly from an almost cloudless sky. Monday and Tuesday were also fine, though it was occasionally cloudy on the latter day. Wednesday was wet and cooler.

— WEATHER IN THE NORTH.—The past fortnight has been marked by cold ungenial weather. Although there has been a good deal of sunshine the nights have frequently been frosty, and high, dry, biting winds have prevailed. On the morning of the 1st there were 3° frost. On Monday the hills all round were whitened nearly to their bases with snow and hail, and there was sharp frost at night.—B. D., S. Perthshire.

— ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, May 11th, in the Drill Hall, James Street, Victoria Street, Westminster, 1 to 5 P.M. At three o'clock a lecture will be given by Mr. G. Massee, F.L.S., on "Diseases of Plants, Especially of Orchids."

— A MARCH GALE.—Mr. R. West, Northlands, Salisbury, writes:—"I send you a photo of the effects of the gale here on Ash Wednesday, but the enclosed can give no idea of the destruction it caused. It nearly cleared the centre of the Scotch Fir plantation. I also send one of an *Araucaria imbricata* growing on the lawn, but it is not a good representation. The specimen is about 45 feet high, well furnished to the ground, and bearing this year seventy-eight cones. It has borne from thirty to fifty cones yearly since 1887." [Each of the photos was very interesting, but unfortunately neither was suitable for reproduction. The *Araucaria* is evidently very handsome.]

— CRYSTAL PALACE SHOW.—The managers of this popular resort have arranged to hold what they term a Great Victorian Era Flower Show on Wednesday and Thursday, June 23rd and 24th. Besides the Crystal Palace commemorative gold medal, £350 is being offered in prizes in the several classes scheduled. What may be termed the principal class is for a miscellaneous group of plants introduced during Her Majesty's reign, to be arranged in a semicircular space not exceeding 500 square feet. The premier award will be the gold medal just mentioned. For a group of *Begonias* £20 is offered, and for an arrangement of *Coniferae* £35; Palms taking a similar amount. The prizes in the remaining classes are equally generous, and a superb display should result. All communications relative to the Show must be addressed to the General Manager, Crystal Palace, S.E.

— *MONSTERA DELICIOSA*.—This handsome Aroid deserves to be more generally known and grown than it is. It is not only one of the most useful and effective of ornamental-foilage stove plants, but is also greatly esteemed for the luscious fruit which it produces when the plant has attained a fair size. In order, however, to thoroughly ripen the fruit, a high and moist temperature is necessary, in addition to which the fruit must be exposed to the sun's rays as much as possible. My object, however, in writing this note is not to direct attention to its fruiting qualities so much as to its great adaptability for planting out to cover bare walls in plant stoves and tropical ferneries. The plants grow luxuriantly against the walls, the long roots cling and penetrate the interstices of the brickwork and descend for many feet into the rock beds below. The peculiar appearance of its roots thus ramifying and descending in every direction, coupled with the beautifully cut or slit-like formation of its handsome dark green foliage, render it a most desirable plant for the purpose I have mentioned; especially so when, as in our case, the interior of the fernery is arranged as naturally and as informally as possible. I need scarcely add that this Aroid, similarly to its congeners, requires abundance of moisture.—S.

— GARDENING APPOINTMENT.—Mr. George Thomas, late foreman at Hutton Hall, Guisborough, has been appointed to succeed Mr. Kneller as head gardener to the Marquis of Ripon at Studley Royal, Ripon, Yorks.

— ROYAL BOTANIC GARDENS.—We learn that Indian *Rhododendrons* and large *Azaleas* are now in flower in the conservatories, and a very good collection of Japanese dwarfed plants, just imported, has been lent to the Society for exhibition by Mr. H. M. Beddington and Mr. Claude Beddington.

— ALL THE YEAR ROUND STOCK.—This is an odd name for a sweet-scented Stock of the Intermediate type, but the appellation seems to be justified by the undoubted fact that if plants be raised from seed sown in July, are kept housed in pots all the winter in a cool house or frame, or if wanted to bloom early, then in a little warmth, they flower profusely all the late winter and spring, then the flowers, hard cut for bunching or other purpose, and the plants after they have broken afresh stood or planted outdoors, they will bloom afresh, and do so all the summer. The variety is one of Messrs. Sutton & Sons' novelties, has flowers of the purest white, and carries 75 per cent. of double flowers.—A. D.

— THE WOOLLY APHIS, OR AMERICAN BLIGHT.—Can anyone tell us why this is called the American blight? I have been asked the question many times when giving lectures or technical instruction on horticulture in Warwickshire, where the pests are rampant. I have also found some very bad cases of Pear trees on walls infested, and consequently difficult to deal with at the back of the branches. I have never met with a case of attack on Plum trees, as stated on page 347. I wonder whether the pest was as prevalent in England before America was discovered? Some old Crab trees one comes across occasionally which are a mass of knobs caused by these pests look as though they had supported these pests some centuries.—J. HAM, *Astwood Bank*.

— INGREDIENTS OF THE SOIL.—Dr. Clark, in a lecture recently delivered at Ripon, said the best way of ascertaining the true character of the soil is to get the plants to tell themselves what the soil does or does not contain. If four plots, each 10 feet by 5 feet, are taken from a grass field and treated with different kinds of manures—the first with potash and phosphate, the second with potash and nitrogen, the third with phosphate and nitrogen, and the fourth with potash, phosphate, and nitrogen—it is possible by comparing the results in each case to ascertain whether the soil is deficient in potash, phosphate, or nitrogen, and to act accordingly. This is a practical test which shows not so much what plant food the soil contains as the amount the plants are capable of getting out of the soil, and it is, in Dr. Clark's opinion, of greater value to farmers than chemical analysis.

— *PYRUS SPECTABILIS*.—One of the most beautiful of the many species of the *Pyrus* grown solely for ornamental purposes is the one under notice. It is a native of China and Japan. In this country it is usually found growing to a height of from 15 to 20 feet, with a large spreading head. The flowers are produced in great abundance about the end of April; they are 2 inches across, pink in colour, and single in the type. There is, however, a variety which has white flowers, and another which has semi-double flowers. The latter for general purposes can be specially recommended, the flowers being of the same colour, and lasting longer than those of the type. The foliage of this plant in autumn is an additional recommendation, the leaves for several weeks before falling being of beautiful shades of orange and red. For large or small gardens this tree will be found acceptable, being easily kept within bounds by careful pruning.—W.

— *PRUNUS PSEUDO-CERASUS*.—A short time ago a plate of this beautiful *Prunus* was published in the *Journal of Horticulture*, and a glance at that cannot fail to impress anyone favourably. Good as the plate is, however, it cannot convey a true idea of the charming picture a fine specimen of this tree makes when in flower. Being of very free growth long strong shoots are made each year, and along the whole length of these the large bunches of flowers shown in the above-mentioned plate are produced. The flowers are often 2 inches across, pink in colour, and semi-double. On different plants, however, the colour varies, some having almost white flowers, whilst others are deep rose. A variety is also in cultivation having greenish-yellow flowers. When planting rich soil should be given, as it is a "gross feeder." Plants growing in good ground flower with much greater freedom than others of the same age planted in poorer soil. This plant is a native of China and Japan. As it becomes better known it is sure to find its way into the front rank of flowering trees.—W. D.

— SUSSEX WEATHER.—The total rainfall at Abbots Leigh, Haywards Heath, was 1.93 inch, being 0.18 inch above the average. The heaviest fall was 0.33, on the 16th. Rain fell on sixteen days. The maximum temperature was 69°, on the 27th; and the minimum 27°, on the 11th. Mean maximum, 54.19°; mean minimum, 38.14°; and the mean temperature was 46.18°, which is 0.76° below the average.—R. I.

— APRIL WEATHER AT DRIFFIELD.—Mean temperature at 9 A.M. (corrected), 45.12°; wet bulb, 42.12°. Mean maximum, 49.76°; mean minimum, 36.26°. Highest, 65.4° on the 29th; lowest, 24.4° on the 11th. Mean of maxima and minima, 43.01°. Mean radiation temperature on the grass, 30.93°; lowest, 16.8° on the 6th. Rainfall, 1.8 inch. Number of rainy days, nineteen; greatest amount on one day 0.33 inch on the 17th.—W. E. LOVEL *Observer, York Road, Driffeld.*

— WEATHER IN SOUTH WALES.—The following is a summary of the weather here for the past month:—Number of days on which rain fell, twenty-one; total fall, 4.84 inches. Maximum on the 17th, 0.83 inch. Mean maximum temperature, 54.1°; mean minimum, 34.6°. Highest reading, 74° on the 28th; lowest, 22° on the 1st. The wind was in the W. and S.W. on twelve days, and in the N. and N.W. on eight days. There were six sunless days. It was very wet until the 21st, as until then we had only two days without rain, with very strong winds the most of the time.—WM. MABBOTT, *Dowlais.*

— PLANT CHEMISTRY.—Of the seventy elementary substances recognised by chemists, only thirteen contribute to the formation of vegetable substances. Out of this baker's dozen all the varied forms of leaf, flower, and fruit are fashioned. Of these thirteen organic elements, three make up more than nine-tenths of all cultivated plants. These are carbon, oxygen, and hydrogen—carbon and water. While these make up the largest part of plants, they are not classed as manures, because they are not applied by hand, but come to the plants from the atmosphere in the form of carbonic acid and rain. They are Nature's free gift to plant life, and are borne on the wings of every wind that blows and the clouds that float aloft.—("California Fruit Grower.")

— BORDER POLYANTHUSES.—Being somewhat of an enthusiast over these lovely spring flowers, I went the other day all the way to Farnham to see a very fine lot at the Swiss Nursery, on Mr. S. Mortimer's invitation. He said he had a grand show, and he seems to have spoken truly. I found there growing and blooming luxuriantly one of the finest breadths, covering some 20 rods of ground, and comprising several thousands of plants, I have ever seen. It was almost strange the plants should have done so finely on what was a piece of rescued sandy heath, everyone having perforce been transplanted last autumn, because the ground on which then growing was needed for greenhouses. What big plants there were! Heads fully 12 inches over, quite massive; the flowers of the finest and richly coloured, indeed other than blue there were almost all other hues, from pure white down to the heaviest purple or crimson. It was indeed a rare pleasure to see such a show of Polyanthus as was here presented, and it is a pity thousands who have gardens could not have seen them, as all would want to grow them. Mr. Mortimer adopts my old plan of sowing seed outdoors at the end of August, leaving the seedlings in the bed all the winter, and dibbling them out in the spring. In that way they become in the second year wonderfully fine bloomers.—A. D.

— WAKEFIELD PAXTON SOCIETY.—At the ordinary weekly meeting of the members of the above Society on Saturday evening, April 24th, there was a good gathering. Mr. B. Whiteley presided, and Mr. J. G. Brown of Outwood occupied the vice-chair. The essayist was Mr. J. Duffan Pearson, Chilwell Nurseries, Nottingham, and his subject was "The Daffodil." Mr. Pearson has paid particular attention for some years to the growth and hybridisation of bulbs, and more particularly Daffodils, a spring flower which has in recent years come prominently to the front. He superintends the cultivation of a vast quantity of these bulbs, varying in price from a few shillings per 100 to £12 12s. each. In order to show the Wakefield Paxtonians what can be done by good management of good bulbs, Mr. Pearson brought a large and varied collection of choice named specimen blooms, and these were capitally staged and displayed, and were much admired. The lecturer spoke at considerable length, and very soon convinced his audience that he was quite at home with his subject. He gave the history of the Daffodil, clearly and fully explained the mode of cultivation, propagation, and hybridising, and gave much interesting information and many valuable hints to professional and amateur gardeners. An interesting discussion took place on the lecture.

— MYOSOTIS DISSITIFLORA.—Rarely have I seen a more effective show of this lovely blue hardy plant than was found just recently in the garden of an amateur near Farnham. He had it for edging his beds and borders; in every direction, indeed, the place was thoroughly blue. Every plant, too, was alike and equally floriferous. No trouble whatever, unfortunately, is taken to save seed, but it falls on the ground, germinates later, and thus gives myriads of plants; for this pretty Forget-me-not is entirely satisfactory only when it is raised yearly from seed. I have known seasons when the seed crop has been so poor I would have given anything to secure such a crop of seed as this amateur's hundreds of plants should give if ordinary care were exercised to save it.—D.

— PROSPECTIVE APPLE CROP IN AMERICA.—A traveller interested in the business of Apple growing who has taken journeys in the various fruit growing sections of the east says that the 1897 crop of the north will in all probability be light, and that the southern crop will be heavy. Last season the Apple crop in the south was exceedingly light, but the yield in New York, Michigan, and other northern States was far in excess of that of any previous year, being so large as to force the price down to almost a point that it would not pay to gather and ship the crop. The Apple tree seldom yields two large crops in succession. It takes a rest, and takes it at least every two years. The southern trees took in 1896 their rest, and reports from all the fruit sections of that region indicate a fine prospect for 1897, the number of fruit buds on the trees being great. But in the north the trees in 1896 did enough work to entitle them to a rest for several years, and the number of fruit buds on them for this season is so small that 1897 will certainly be one of their years for rest. Hence the north cannot raise a large crop in 1897, and with even fair conditions from now on the south will have an excellent yield.—("California Fruit Grower.")

— FORESTRY IN SWEDEN.—The Crown forests of Sweden comprise more than one-quarter of the entire wooded area of the country, and are managed with scrupulous care. The increase alone is cut, so that a productive forest is to stand for ever on all Crown lands that are unsuitable for cultivation. More than this, the Government has entered upon an extensive system of planting trees on desolate and uncultivated areas, and these object lessons have induced owners of private forests, especially the larger proprietors, to manage their timber lands, so they will become permanent sources of income. These facts, says an American contemporary, were communicated to our Department of State by Hon. W. W. Thomas, United States Minister to Sweden, and they are of particular interest, not only to Sweden, but also to the United States and to Canada, whose lumber meets the Swedish product as its greatest competitor in the markets of the world. Since the forests in Sweden grow slowly it has generally been supposed that the immense quantities exported would gradually exhaust this most important source of the nation's wealth, but from the facts stated it appears probable that the 47,000,000 acres of forests in the country will continue to be a source of income for all future time. The products of the forests now comprise nearly one-half of the total exports of the country in value.

— HAMPTON COURT PALACE GARDENS.—The springtime is with us, although at the moment of writing not very pleasantly tempered to coolness by keen north-easterly winds and sharp white frosts—doubtless a touch of the very old traditional Blackthorn winter. But in spite of that the spring flowers so commonly called, really border Polyanthus at Hampton Court, show now that it is the spring season, and in but a few days more will be at their best. The thousands of fine plants now blooming in beds and borders are reminders of Mr. Archibald Graham's and his old foreman Mr. Barnshaw's love for Polyanthus. It is to be hoped that the new superintendent, Mr. Gardener, will inherit that taste, and indeed see how to improve upon what has so far been so admirably done. At present the collection comprises too many light colours, especially white and pale yellow. These in every case should be selected and grouped separately. Then also the finest of each colour ought to be removed from the beds as soon as they show quality and be blocked separately into a reserve garden to give seed, their place in the bed being taken by reserve plants. The same should be done with the fewer deep-coloured forms, as of these there are far too many spotted or bizarre flowers that are mixed very ineffective. In all cases there are superior varieties found that merit the greatest care. The Tulips employed to give variety to the Polyanthus are very poor and small. Pinks do not harmonise at all. Whites, yellows, and crimsons are by far the best. It is hoped that the Board of Works will be more liberal in the matter of Tulips another year. The public now visit the gardens in great numbers on fine days, for they are a most popular resort.—A.

ROSE SHOW FIXTURES FOR 1897.

- June 7th (Monday).—Cambridge.
 " 9th (Wednesday).—Chelmsford.
 " 15th (Tuesday).—Ryde.
 " 18th (Friday).—Portsmouth (N.R.S.).
 " 23rd (Wednesday).—Richmond, Surrey.
 " 24th (Thursday).—Colchester.
 " 25th (Friday).—Maidstone.
 " 26th (Saturday).—Windsor and Dorking.
 " 29th (Tuesday).—Canterbury, Hereford, Sutton, and Westminster (R.H.S.).
 " 30th (Wednesday).—Croydon, Ealing, and Reading.
 July 2nd (Friday).—Crystal Palace (N.R.S.).
 " 7th (Wednesday).—Glasgow, Hanley,* Hitchin, Reigate, Leeds,† and Tunbridge Wells.
 " 8th (Thursday).—Bath, Gloucester, Harrow, Newcastle-on-Tyne, and Woodbridge.
 " 13th (Tuesday).—Wolverhampton.†
 " 15th (Thursday).—Norwich (N.R.S.) and Helensburgh.
 " 17th (Saturday).—New Brighton.
 " 22nd (Thursday).—Halifax and Trentham.
 " 27th (Tuesday).—Tibshelf.
 " 28th (Wednesday).—Chester.*

* A show lasting two days. † Shows lasting three days.

The above are the only dates that have as yet reached me. I shall be glad to insert in the next list any further fixtures that may be sent me, whether of Rose shows or of horticultural exhibitions where Roses form a leading feature.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

NATIONAL ROSE SOCIETY.

SOUTHERN SHOW.

THIS year the National Rose Society will hold its Southern Show in the Victoria Park, Portsmouth, on Friday, June 18th, in conjunction with the Isle of Wight Rose Society. The parent Society schedules twenty-six classes, and the prizes consist of cups and money. This Southern meeting is happily becoming more and more popular every year, and it is to be hoped that the great seaport will thoroughly uphold the reputation that has been achieved at the many other towns visited in previous years. The near approach of the Jubilee festivities may perhaps tell slightly against the show, but not, it is anticipated, very much. The weather, by which Roses and rosarians are so much, and sometimes so hardly governed, will have great influence, and all growers will be glad to see the last of the cold easterly and north-easterly winds that have prevailed of late.

METROPOLITAN SHOW.

Friday, July 2nd, will, it is hoped, find the Crystal Palace once more a feast of Roses, for on that day the N.R.S. holds its great metropolitan show. Every Rose grower who is an exhibitor strives his utmost to be at the Palace, and those who do not stage go to criticise, and sometimes condemn, the flowers of those who do. The centre transept on show day is a picture of beauty and a dream of fragrance. Already speculations are afloat as to who will win the trophies, but the time of year is young, too much so, in fact, for anyone to prophesy with any confidence and likelihood of being correct. If the weather be kind to all growers we shall see an exhibition that will be worthy of the year, even amongst the many magnificent schemes that are afoot in celebration of Her Majesty's Diamond Jubilee. Owing to adverse circumstances the competition in many classes was decidedly weak last year, while the blooms in several instances were not at all in character; but, all being well, it is hoped the contest this year will be keener by reason of both the increased number and the higher quality of the flowers staged.

NORTHERN SHOW.

Excellent have been the Roses staged at many shows by the growers of the Eastern Counties, and this year they will on Thursday, July 15th, at Carrow Priory, Norwich, have an opportunity of improving their reputation by taking some of the prizes offered by the N.R.S. Amongst the thirty-four classes enumerated in the schedule there are two in which "Jubilee trophies" are offered, one to nurserymen, and the other to amateurs. The first-named class is for thirty-six distinct single trusses, and the winner will hold the 50-guinea challenge trophy, receiving in addition a Memorial gold medal. The amateurs' class is for twenty-four distinct single trusses, and again the 50-guinea trophy will be held by the premier winner for one year, and a Memorial gold medal. The local society known as the Norfolk and Norwich Horticultural Society will hold its annual show at the same time and place.

HARDY FLOWER NOTES.

WITH all the wealth of other flowers, we welcome the first of the Tulips to bloom. The Tulip has its faults, but it has its glories too, and ere the season is over I hope to say something of some of the rarer species and varieties yet to flower. Reading the other day in Henry Van Oosten's curious old work, "The Dutch Gardener or, the Compleat Florist," the first English translation of which was published in 1703, I was amused by his indignation at the criticism the Tulip received even in his day. Van Oosten seemed to think it necessary to defend or excuse the absence of perfume in what appears to have been his favourite flower. In the chapter headed "How you may judge whether a Tulip be handsome or no," he says that those who love the July flowers (Carnations) more than the Tulips "would do well to consider that Flowers ought chiefly to please the Sight and that the Smell gives them no Beauty." He proceeds:—"And they who value Flowers chiefly for their smell may supply themselves with Perfumes and not upbraid this Queen of Flowers for want of that Quality which derogates not in the least from her Beauty, nor renders her less pleasing in a Florist's Eye."

Yet Van Oosten notwithstanding, most of us will admit that the pleasant perfume of some other flowers, present in only a few of the Tulips, would be very acceptable in these flowers, which, when we understand their value aright by study of their most effective uses, will be even more appreciated than now, popular as they are. The first of my Tulips came into flower somewhere about the 6th or 7th of April. This was one of several lots of wild dwarf species, collected and sent by our good friend Mr. Edward Whittall, of Smyrna, in 1894 or 1895. It appears to be closely allied to *T. Biebersteiniana*, which is itself a variety of *sylvestris*. The flowers are bright yellow, and open out well in the sun, making a bright spot on the rockery on which they grow. This Tulip is only about 6 inches high. The only distinguishing marks on the parcel were the numbers attached by Mr. Whittall, which are 555 No. 1; but I hope he may be able to supply me with more information, if he has got the species identified at Kew.

The next to bloom was that noble Tulip, *Greigi aurea zonata*, of the beauty of whose spotted leaves and grand crimson and yellow flowers I have before spoken. I have not yet enjoyed a glimpse of it this season, but the recollection of the past beauty of former years is indelibly imprinted upon my memory, and the name of the flower brings afresh to view its glossiness and exquisite colouring. The next have been two out of a number of bulbs collected in Chios by a good friend of mine, Mr. D. W. Leighton of the Eastern Telegraph Company, now temporarily on duty in that disturbed island, Crete. These Tulips, belonging to the same section as *Oculus-solis*, are rather tall, but of very beautiful colouring. Pink is hardly the word to describe the colouring, but it might do if we could imagine a transfusion of terra-cotta through the deeper colouring of the segments. The fine *Tulipa Kaufmanniana*, honoured by the Royal Horticultural Society with a first-class certificate at a late meeting, is not going to flower this year; but as I spoke of it last spring I need not refer to it further at present. This was figured on page 335.

It is evident that there is an increasing interest in such Tulips as these which owe none of their beauty to the florists' art. Though this is the case we may yet hope to see them taken in hand with a view to securing greater variety and more beautiful flowers. Among the species in cultivation there is none more distinct than *Tulipa biflora*, whose flowers are not borne singly on the stem, as is usual in the genus, but are produced in greater numbers, from two to five being generally found. This Tulip looks odd in its way beside the others, its forking stems attracting attention by their peculiarity. The flowers, white with yellow eye inside and tinged with green on the exterior, look quiet and unassuming if compared with their more showy sisters. For a quiet nook in the rock garden there may be brighter, but there will be few more interesting flowers. *T. biflora* was introduced from the Caucasus about ninety years ago, and forms, we are told, the connecting link between the true Tulips and those of the sub-genus *Orithya*. The form here is the larger one known as *biflora* major. It requires no special advice as to cultivation, unless one may suggest that it might have a place sheltered as far as possible from late spring frosts, my flowers having been destroyed this year from this cause.

One may, at present, bring to a close these remarks on Tulips with a reference to an early-flowering one not coming within the category of the popular Dutch varieties now so brilliant in the garden. There are many Tulips which were grown long ago, but were relegated to obscurity when these plants became valued as "bedders" only, with the result that only those of the gayest colours, or of a distant effect, were in favour. How much we lost by this we begin to feel now; but happily in odd corners of

bulb nurseries, and in old gardens, some remained undestroyed. The beautiful variety Dame Elégante, in flower as I write, is one of these. Shenstone could never have seen a flower like this, or

such sentiments as these. She is a dainty, shapely, creamy yellow flower, with narrow carmine stripes, not unworthy of the name she has received. Mr. W. B. Hartland, of Cork, in his "Little

FIG. 79—SANGUINARIA CANADENSIS GRANDIFLORA

he would never have spoken as he did of the "gross splendours" of the Tulip, which are, he said, "inelegantly gay" in the distance, and "To the near view no pleasing charms display." Dame Elégante could by no possibility rouse (we cannot say inspire)

Book of Tulips," tells us that Dame Elégante is of French origin. However this may be, we hope she may long find a home in the gardens of the British Isles to give true pleasure to their owners and their friends.

These are only a few of the garden's delights. The Puccoon or Bloodroot, *Sanguinaria canadensis*, the large flowered variety of which, *S. c. grandiflora*, is depicted in fig. 79, spreads open its white blossoms to the midday sun. Primroses and Polyanthus of nearly all hues shine in shady corners. *Primula* species form objects of admiring glances from those who know their beauties. Alpine Auriculas look out here and there from the rock garden. Coloured varieties of *Anemone nemorosa* contrast with the purity of their snow-like sisters, or vie with *A. apennina*, though eclipsed by the Poppy Anemones or *A. fulgens*. *Doronicums*—Golden Marguerites—make masses of gold. Purple and white *Honesty*, blue Forget-me-nots, *Violas*, *Violets* of delicious fragrance, *Fumitories*, and others seek to charm us. Why prolong the tale? We cannot do more just now, and ere we take up the story again a fresh band of Earth's fair children will have made their appearance. Fair are they, and as years run on dearer do they become to him who looks upon them with loving eye. The garden of hardy flowers has its sorrows and its disappointments, but these are far outweighed by its joys and rewards. Pure and precious are these, not to be weighed nor measured, so overflowing are they with Heaven's bounties.—S. ARNOTT.

ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE, APRIL 27TH.—Present: Dr. M. T. Masters (in the chair); Rev. W. Wilks, Rev. G. Henslow, Hon. Sec.

Tulips Diseased.—With reference to the Tulips "Golden Crown" sent to the last meeting by Mr. Thomas of Polegate, the following is the report received from Kew:—"The leaves are attacked by a fungus called *Botrytis vulgaris*, a destructive parasite to various bulbous plants. The mycelium of the fungus travels down the tissues of the host plant and forms minute sclerotia in the bulb and also in the soil in which the plant is growing. These sclerotia remain dormant during the winter, and commence to grow the following spring when the young leaves appear. Your correspondent is right in supposing that he will get no blooms. The wisest thing to do would be to remove all the diseased plants. It would not be wise to plant bulbs in the soil where the diseased plants have grown for the next two years. If this cannot conveniently be avoided, then let him plant 'trap-plants'—that is, comparatively worthless bulbs—to take up the spores and sclerotia present in the soil, and then remove them early in the summer before more sclerotia or spores are formed."

Podisoma sabinae.—Mr. E. Pollard of Colwall, Great Malvern, sent a specimen of *Savin* having the yellow jelly-like outgrowth from the stem of this fungus. It is dimorphic, the second stage being called *Rastelia cancellata*, and is found growing on rosaceous trees.

Pinus Torreyana.—Dr. Masters exhibited specimens of the large cones of this tree. It was found on the extreme southern coast of California, extending over about three to four miles only, and the group consisted of from 200 to 300 trees. It has since been discovered on the island of Santa Roza off the same coast. It is now in cultivation.

Lilies Diseased.—Mr. Noy of Brentford sent some Lilies. Some grown on land heavily manured with sewerage matter and ashes; others on land which had not been manured for several years, being a very light soil. They were attacked with a species of *Peronospora*, allied to the Potato disease; so possibly a treatment similar to that for Potatoes might be advantageous.

Tulip with Axillary Flower.—Mr. Townell, of Heaton, Newcastle-on-Tyne, sent a specimen of the Tulip "Proserpine," in which an additional small flower sprang from the axil of a leaf on the scape. It is not a common production, but similar growths occasionally occur.

Cineraria Crosses.—Messrs. James & Son of Farnham Royal sent several fine grown plants, which they had raised (1) between *Cineraria cruentus* crossed with garden forms, and four plants (2, 3, 4, 5) resulting from this; also (1) again crossed with *C. Heritieri* (6); also this last true species crossed with the first named (1). It had white flowers, with pink tips to the petals. Of the four plants, numbered 2, 3, 4, 5, No. 2 had foliage more resembling that of *C. cruentus*, but 3, 4, and 5 that of *C. Heritieri*, while three had a white ray and pink disk; 5 had both ray and disk of a crimson colour.

NATURAL BEAUTY IN PLEASURE GROUNDS.

PERMIT me to congratulate you in your promising recruit, "A Young Scot" (page 320). Amid many losses of grand old men and changes in hallowed places, it is pleasing to find new writers crowding into the ranks. Amid these I am glad to heartily welcome into the literary arena one that I can recognise through his safe disguise as a pupil of my own—"A Young Scot." As he has already learned that Simplicity weds with Negligence in Nature, and got smitten with the love of Birches, he cannot do better than clothe their silvery stems with a few graceful sprays of streaming Roses. With such a promising start "Young Scot" may in time make himself a place and a power in enlivening and ennobling not a few of our somewhat sombre and severe landscapes. The dying Goethe is said to have called for Light, more Light. Perhaps nine out of ten of our landscapes pine for greater freedom, sweeter grace, richer colouring; and it is hoped that there may be many other "Young Scots" spring up, and try their prentice

hands "on" forest pictures, in gardens, and in other ways, that shall mould the stiffly formal into the pleasing picturesque. Landscape gardeners, young and old, must carry the lesson that has become an axiom in other spheres of life into the garden—viz., that beauty or Nature unadorned is often adorned the most.—D. T. F.

ROYAL GARDENERS' ORPHAN FUND.

ON the 30th ult. nearly a hundred friends and members of this Charity gathered at the Hotel Cecil for the annual festival dinner. The chair was taken at 6.30 P.M. by Sir J. Whittaker Ellis, Bart., who was supported by Mr. Sheriff Rogers, Mr. N. N. Sherwood, Mr. H. J. Veitch, Mr. P. Crowley, Rev. W. Wilks, Mr. G. A. Dickson, and other well-known horticulturists. After dinner the Chairman gave the usual loyal toasts, which were enthusiastically received.

Sir J. WHITTAKER ELLIS, Bart., in proposing "Prosperity to the Royal Gardeners' Orphan Fund," expressed the opinion that the Charity deserved the consideration of all who derived any benefit from or had any interest in the work of the gardener. No profession was more important than that of horticulture, and none required so much skill and patience. The Chairman considered the system of provision made by the executive was admirable; it was far better to leave the children to the influences of home life, under the care of trustworthy people, than to place them together in one large school or home. He appealed to gardeners throughout the country to give what they could towards the feeding, clothing, and education of gardeners' orphans; and not only did he wish gardeners to subscribe as far as they were able, but he thought they might go a step farther and enlist the sympathy and help of their employers for so deserving an object. To obtain a large increase in the funds methodical and unanimous effort must be made, and they should look rather to the many small subscriptions than to the few large ones. His own experience of gardeners, extending over fifty years, was that they were the most painstaking, careful, and honest of servants. The only difficulty that ever arose was when a gardener so loved and cared for the garden and its contents that he objected to his employer doing anything more than admire what he produced. He had no cause to complain of lack of interest on the servant's part, and thought that good employers made good servants, and these in turn good employers. Sir J. Whittaker Ellis concluded by asking those present to use their best endeavours to make this memorable year a notable one in the history of the Fund by subscribing liberally to it. Loud applause followed the speech, which was in all respects an admirable one.

Mr. N. N. SHERWOOD, Treasurer to the Orphan Fund, responded to this toast, and took the opportunity to thank Sir J. Whittaker Ellis for his presence and help. He briefly showed the progress of the Charity since its inception in 1887, and expressed a hope that much more would yet be done. He admired the speech made by Mr. Owen Thomas on the occasion of the annual meeting, and trusted gardeners would all follow the advice then given. As Treasurer he desired to see more annual subscribers, and he hoped that the subscription list for 1897 would be exceptionally large, as would become so exceptional a year.

Mr. G. A. DICKSON of Chester proposed "Gardeners and Gardening." He admired the patience, industry, and skill of gardeners, and the wonderful results they obtained, even under adverse circumstances. In the coldest parts of Yorkshire and still farther north he had seen fine examples of the gardener's art in the plentiful supply of fruits, flowers, and vegetables, and the beautification of what were previously unlovely spots. He agreed with a friend of his, who had a splendid collection of oil paintings, that the garden was a finer picture than any canvas; a good garden seen in the varying moods of Nature, in storm and sunshine, in the warmth of spring and summer and the cold of winter, afforded continued pleasure and an unfailing interest. Mr. Dickson was glad to find a great extension of the love and practice of gardening, and he hoped that now commercial prosperity had returned more money would be expended upon gardeners and gardening than had been the case in the past.

The Rev. W. WILKS made an able speech in response to this toast. He reminded the gathering that now, as when Adam was the only gardener, good gardening was the result of hard work. The "sweat of the brow" was needed always to induce the earth to yield her increase. No body of men worked harder or more continuously than gardeners, and few received lower wages. A gardener had no interest in the eight-hour day question, for he had to be up and doing at early morn, and in the most unpleasant weather it was necessary for him to go out and attend to the fires when other folks were comfortably warm and in bed. This patient care and continuous work resulted in the provision of both necessities and luxuries for the employer, and those who were indebted for so much to the gardener should, he declared, do their utmost to encourage him. One of the best means of encouragement was to subscribe liberally to the Orphan Fund. The reverend gentleman appealed to all who assisted the Charity not to reduce their subscription this year in consequence of the many other appeals, but to let exceptional claims made to commemorate the long reign of Her Majesty be met from an exceptional purse; the Institution they had met to support should not be allowed to suffer while we paid special honour to our Sovereign.

"The Health of the Chairman," suitably proposed by Mr. Poupart, in the absence of Sir James Whitehead, was given with musical honours and cheers. Sir J. Whittaker Ellis, in thanking the meeting for the toast, expressed the pleasure he felt at being able to assist gardeners in any way, and he should take care that none of his friends should escape the question, "Do you subscribe to the Gardeners' Orphan

Fund?" The next item was the reading of the subscription list by Mr. B. Wynne, as follows:—

Sir J. Whittaker Ellis, £194 10s (including 50 guineas himself and £100 from Mr. Leonard Sutton); Sir James Whitehead, £10 10s.; Mr. G. Reynolds, £36 1s. 6d. (including Leopold de Rothschild, Esq., £10 and Mr. Anthony Waterer, £5); Covent Garden friends, per Mr. J. Asabee, £45 10s.; Messrs. Rothschilds, £26 5s.; Mr. N. N. Sherwood, £38 2s.; Baron Schöler, £25; Mr. A. W. G. Weeks, £20 8s.; Mr. Alfred de Rothschild, £10; Dickson's, Ltd., £10 10s.; Mr. Harry J. Veitch, £10 10s.; Messrs. J. Veitch & Sons, £10 10s.; Messrs. Barr & Son, £10 10s.; Mr. D. P. Laird, £9 1s.; Mr. W. Poupart, £9; Mr. W. G. Baker, £8 8s.; Mr. W. J. Nutting, £7 17s. 6d.; Mr. F. T. McKenzie, £8 3s.; Mr. K. Drost, £7 7s.; Mr. J. F. McLeod, £7 5s.; Mr. E. Gilbert, £5 10s. 6d.; Mr. Geo. Bunyard, £5 5s.; Mr. A. H. Smee, £5; Mr. A. W. Sutton, £5; Mr. J. Walker, £5; Mr. T. Whillans, £5 12s. 6d.; Mr. P. Crowley, £7 2s.; Mr. G. A. Dickson, £5 5s.; Mr. Blackwood, £5; Mr. S. C. Ward, £5 7s.; Mr. G. H. Richards, £5; Mr. S. M. Segar, £5; and Mr. W. H. Holmes, £5 5s. These, with several smaller amounts, making a total of £670.

The toast of "The Visitors" was ably proposed by Mr. Arnold Moss, and admirably responded to by Mr. Sheriff Rogers, who paid tribute to the ability of Mr. W. Marshall, as Chairman of the Committee. At this point the Chairman retired, and his place was taken by Mr. N. N. Sherwood. A vote of thanks was accorded Miss Hudson, and the donors of the fruits and flowers for the dinner, the many vases of drooping Parrot Tulips, given by Mr. J. Walker, having a beautiful effect. Other toasts were "The Treasurer" and "The Secretary, Mr. A. F. Barron."

An excellent programme of music was arranged by Mr. Herbert Schartau, and his efforts during the evening were thoroughly appreciated.

THE CARROT FLY (PSILA ROSÆ).

CARROTS are frequently much injured by the larvæ or maggots of this fly, which bore into and feed upon their roots, living upon them and causing them to become brown or rusty, and finally rotten. In some cases of early attack the growth of the small roots is entirely stopped. Carrots grown by market gardeners and market garden farmers for "bunching," or pulling early, are not often materially injured, as the fly does not, as a rule, attack them until the middle of May, though the latest of these early pulled roots are sometimes disfigured and their value depreciated because of the rusty spots made by the larvæ; but those that are dug late for storing, either for human or for cattle food, are very frequently seriously damaged, and rot in the clamps and stores, and are unsaleable by reason of the rust marks upon them. It has been noticed that the Carrot fly is more injurious in dry seasons, when the growth of the roots is not so luxuriant and rapid as when moisture is plentiful and the rain closes the soil, which in some degree may hinder the fly from laying eggs, as it is said that the female fly goes below the earth for this purpose.

Carrots badly attacked by this insect have deep cracks in the roots in which the larvæ are found. These frequently extend to the centre of the roots, and cause them to rot. The tops become brown and wither away, and in the early stages of the attack, when as yet there are only a few larvæ in the roots, the foliage changes and betrays their presence. When these indications are noticed, it will be generally found upon pulling up the roots that larvæ are protruding from the holes in them. In bad cases of this infestation, decay is frequently hastened by the attacks of millipedes attracted by the unhealthy state of the roots, and by slugs and "pea bugs" (*Oniscus*). The larvæ of the Carrot fly often remain in the roots after they have been stored, and continue to injure them for some time.

The Carrot fly is well known in Germany. Kühn says it causes the most common disorder of Carrots termed "worm-rot" (*Wurmfaule*) and the "iron mould" affection. It is also occasionally troublesome in France and in other European countries. Recently it has been noticed in Canada. Schiner states that it infests Rape and Turnips, and that the flies may be found in numbers in the early spring on the over branches of bushes and trees in damp situations.

LIFE HISTORY.

The Carrot fly is shiny black in colour, and about the fifth of an inch long, with a wing expanse of nearly half an inch. The wings are iridescent, having dark yellow veins. The head is round, of a reddish yellow colour, and very sparingly covered with hairs. The legs are of a light ochreous colour. There is not much difference between the male and female, except that the body of the latter is more pointed than that of the male, and is furnished with a long retractile egg depositor.

In the early spring the flies appear, and may be seen upon the lower leaves of trees and bushes, especially near brooks and streams. When the Carrot roots are well established the flies lay eggs upon them, just below the ground. All authorities agree that the eggs are laid below the surface of the ground, but none have actually observed how deeply the fly goes down for this purpose. It is believed that it is only just below the surface, and that the larva when hatched goes down instinctively to the lower part of the Carrot, as the root is softer there and more easily penetrated. When it has gained a footing the larva works upwards and makes passages, with frequent holes to the outside. The larva is without legs, yellowish white in colour, like parchment, as Bouché says, and nearly a quarter of an inch long. It has no distinct head; but its fore end tapers to a point, in which there are two claw-formed hooks for biting and boring. Before pupating it leaves the root,

and, going into the earth, assumes a pupa case of a light brown colour, with many wrinkled folds. At the tail end two small black points are seen. The head end is very sloping.

There are several generations during the summer. Kühn states that the series of changes is accomplished in between three and four weeks. The pupæ of the last generations remain in the earth, and occasionally in the roots, during the winter, and the flies come forth in the first spring days.

METHODS OF PREVENTION AND REMEDIES.

When it is noticed that the tops of Carrots change colour prematurely and become rusty, the roots should be examined, and those that are infested must be forked up so that no part of them is left in the ground, and destroyed. This will prevent further infestation.

If the flies are seen near or on the Carrot plants they should be sprinkled with paraffin emulsion, made by mixing paraffin and softsoap together, in the proportion of 1 gallon of paraffin and half a pound of softsoap to 10 gallons of water. The softsoap must be dissolved in a gallon of hot water, and the paraffin added and thoroughly incorporated by means of a hand pump or syringe, and the proper quantity of water, added to dilute it. This emulsion can be put on by means of a knapsack machine, or in large fields of Carrots by a horse distributor.

FIG. 80.—CARROT FLY AND LARVÆ.

1, 2, and 3, Larvæ, natural size and magnified; 4, infested Carrot; 5 and 6, pupæ; 7 and 8, Carrot Fly, natural size and magnified.

In places where these flies cause injury, ashes, sawdust, sand, wood ashes, or peat moss, well triturated and impregnated with paraffin oil at the rate of from 3 to 4 quarts per cwt. may be put into the drills with the seed. Curtis recommends a gallon of spirit of tar to a barrowful of sand for this purpose. It is stated that pressing the earth close round the root stems may prevent the flies from egg-laying. This may be done immediately after the plants are singled, by men or boys treading both sides of the rows; and in fields where Carrots are grown on a large scale, and the seed is broadcasted, a light roller may be used for this purpose.

Sand or ashes impregnated with paraffin or carbolic acid may be scattered over the plants at singling time to keep the flies from them. The great object must be to prevent the flies from laying eggs on the Carrots, and for this purpose offensive substances, such as soot, or earth, ashes, or sand, sprinkled with carbolic acid, might be applied as soon as the plants are well established.

After an infested Carrot crop has been removed, the land should be trenched in gardens, and very deeply ploughed in fields. A good dressing of gas lime should be applied before the land is dug or ploughed in the ordinary way.—(*Board of Agriculture Leaflet, No. 38*)

NATIONAL AURICULA SOCIETY.

(NORTHERN SECTION.)

THIS Society held a most successful Exhibition in the Free Library, Middleton, near Manchester, on Saturday last, May 1st. Both plants and exhibitors were present in unprecedentedly large numbers, and all the classes were well filled. The date chosen seemed to suit every one, and competitors from districts so widely apart as Birmingham and North Yorkshire were enabled to meet on apparently equal terms.

The Rev. F. D. Horner brought his superb seedlings in splendid order, admiring growers yearned to possess them with a kind of hope deferred expression on their faces, which was almost pitiful. It is much to be regretted that Messrs. Horner's and Simonite's highly bred varieties increase so slowly, for a great impetus would be given to the cult could some of them get into general cultivation. Mr. Tom Lord of Todmorden again showed what could be done with the old varieties. It is always a treat to see Geo. Lightbody, Rev. F. D. Horner, Acme, Prince of Greens, and Mrs. Potts as grown by him. Miss Woodhead, Mr. Kershaw, Mr. Midgley, and Mr. A. R. Brown also showed the older varieties in most creditable style.

The premier Auricula was a superb example of Barlow's Mrs. Henwood, exhibited by the Rev. F. D. Horner. A curious feature of the show was the excellence of the green edged class; a few years back this division was very weak, but thanks to the labours of seedling raisers, which appear to have been concentrated upon this class, it is now actually the strongest. Amongst fine new green edges Orient and Hamlet (Horner), Shirley Hibberd and Chloe (Simonite), and Mrs. Henwood (Barlow) may be mentioned. Messrs. Lord and Kershaw also showed good unnamed seedling greens.

In grey edges not so much has been done, Mr. Horner's Greyhound

and Eyebright being the only novelties of note, except a promising seedling of Mr. Harrison's. White edges were not of great excellence, the only varieties to rival Acme being Mr. Horner's Magpie and Miranda. Selfs were excellently shown by Messrs. Horner, Lord, Bentley, and Simonite. The ubiquitous Mrs. Potts was in good form. Mr. Horner's Midnight, Dusk, Eurydice, Favourite, and Titania, and Mr. Bentley's Gerald completely throw into the shade most of the older varieties.

Alpines were magnificently shown. In this popular class the number of fine novelties was almost bewildering. Mr. Gorton had some superb unnamed seedlings. Mr. A. R. Brown proved that the southern florists were in no ways behind the men of the north. Mr. Beswick showed Richard Gorton, a beautifully proportioned variety of uncommon shade of bright brownish red, which deservedly won the prize for the best Alpine in the exhibition. Mr. Lees had also a charming white ground seedling. Mr. Bentley showed Charles W. Needham, which is all an Alpine needs to be, and the exhibits of Messrs. Buckley, Stelfox, and Lord showed that they thoroughly knew how this charming flower ought to be grown. In Polyanthus Messrs. Thornley, Beswick, and Stringer showed the old varieties in good style, and Mr. Prescott showed two promising seedlings. The Judges made the following awards:—

Class A.—Six dissimilar Auriculas.—First, Rev. F. D. Horner, Barton-in-Lonsdale, with Eurydice and Midnight (selfs), Magpie, Mrs. Henwood, Shirley Hibberd, and Geo. Lightbody. Second, Mr. T. Lord, Todmorden, with Mrs. Potts, Rev. F. D. Horner, Prince of Greens, seedling green edge, George Lightbody, and Acme. Third, Miss Woodhead, Halifax, with Mrs. Potts, Rev. F. D. Horner, George Lightbody, Traill's Beauty, and Acme. Fourth, Mr. W. H. Midgley, Halifax, with Mrs. Potts, Rev. F. D. Horner, Rachel, George Lightbody, Conservative, and Mrs. Dodwell. Fifth, Mr. A. R. Brown, Birmingham, with Mrs. Potts, Rev. F. D. Horner, George Lightbody, Richard Headly, Heather Bell, and Black Bess. Sixth, Mr. G. Middleton, Prestwich, with Negro, Rev. F. D. Horner, George Rudd, Rachel, Smiling Beauty, and John Waterston. Seventh, Mr. J. Clements, Birmingham, with Mrs. Potts, Rev. F. D. Horner, Brunette, C. E. Brown, George Rudd, and Mrs. Dodwell. There were nine exhibits in this class.

Class B.—Four dissimilar Auriculas.—First, Rev. F. D. Horner, with Favourite, self; Shirley Hibberd, Greyhound, and Miranda. Second, Mr. W. Kershaw, Ashton-under-Lyne, with Mrs. Potts, Rev. F. D. Horner, George Lightbody, and Mrs. Dodwell. Third, Mr. T. Lord, with Mrs. Potts, Rev. F. D. Horner, George Lightbody, and Acme. Fourth, Mr. W. H. Midgley, with Mrs. Potts, Rev. F. D. Horner, George Lightbody, and Acme. Fifth, Mr. J. Wood, Staleybridge, with Blue Peter, Rev. F. D. Horner, W. Brockbank, and Heather Bell. Sixth, Mr. A. E. Brown, with Mrs. Potts, Rev. F. D. Horner, George Lightbody, and Heather Bell. Seventh, Mr. Stelfox, Staleybridge, with Blue Peter, Mars, Rachel, and Heather Bell. There were sixteen exhibitors in this class.

Class C.—Pairs of Auriculas.—First, Mr. E. Shaw, Moston, with Mrs. Potts and George Lightbody. Second, Mr. Kershaw, with Rev. F. D. Horner and Acme. Third, Mr. R. Gorton, Eccles, with John Hannaford and Heather Bell. Fourth, Mr. J. Stokes, Birmingham, with Mrs. Potts and Rev. F. D. Horner. Fifth, Mr. G. Thornley, Middleton, with Mrs. Potts and Traill's Beauty. Sixth, Mr. J. Stelfox, with Mrs. Potts and Geo. Rudd. Seventh, Mr. J. W. Bentley, Middleton, with Mrs. Potts and Rev. F. D. Horner.

Class D.—Pairs for maiden growers.—First, Mr. J. Harrison, Congleton, with George Rudd and Seedling. Second, Mr. W. Stringer, Middleton, with Mrs. Potts and Acme. Third, Mr. W. M. Shipman, Altrincham, with Mrs. Potts and Rev. F. D. Horner.

Class E.—Single plants, green edges.—First and second, Rev. F. D. Horner, with Hamlet and Orient. Third, Mr. Lord, with a Seedling. Fourth, Mr. Midgley, with Rev. F. D. Horner. Fifth, Mr. Simonite, Sheffield, with Seedling. Sixth, Mr. Kershaw, with Seedling. Seventh, Mr. Lord, with Prince of Greens. Eighth, Rev. F. D. Horner, with Shirley Hibberd.

Class F.—Single plants, grey edges.—First, Miss Woodhead, with Rachel. Second, Rev. F. D. Horner, with Seedling. Third, Mr. E. Shaw, with Dinham. Fourth, Mr. Lord, with Geo. Lightbody. Fifth, Rev. F. D. Horner, with Eyebright. Sixth, Mr. Kershaw, with Richard Headly. Seventh, Mr. Shaw, with Conservative. Eighth, Mr. T. Buckley, with George Rudd.

Class G.—Single plants, white edges.—First, Mr. Lord, with Heather Bell. Second, Rev. F. D. Horner, with Magpie. Third, Mr. Lord, with Smiling Beauty. Fourth, Mr. Lord, with Acme. Fifth, Rev. F. D. Horner, with Miranda. Sixth, Miss Woodhead, with Conservative. Seventh, Mr. Stelfox, with Dr. Kidd. Eighth, Mr. Wood, with Frank Simonite.

Class H.—Single plants, selfs.—First, Mr. Lord, with Mrs. Potts. Second, Rev. F. D. Horner, with Dusk. Third, Mr. Bentley, with Gerald. Fourth, Rev. F. D. Horner, with Eurydice. Fifth, Rev. F. D. Horner, with Titania. Sixth, Mr. Simonite, with Seedling. Seventh, Mr. Lord, with Red Perfection. Eighth, Mr. Midgley, with Heroine. Premier Auricula, Rev. F. D. Horner, with Mrs. Henwood.

ALPINES.

Class I.—Six dissimilar Alpines.—First, Mr. A. R. Brown, Birmingham, with Fred Knighton, Winnifred, Dr. Knott, A. A. Jones, Countess, and J. F. Kew. Second, Mr. T. Buckley, with Dr. Durnford, John Allen, Mrs. Beswick, Bright Eyes, Forest Queen, and Dr. Knott. Third, Mr. R. Gorton, with Dreadnought, John Allen, and four fine seedlings. Fourth, Mr. J. Stelfox, with Bright Eyes, Dr. Knott, Dr. Durnford, John Allen, Emir, and Forest Queen. Fifth, Mr. J. Beswick, with Bright Eyes, Mrs. Beswick, Forest Queen, Rev. F. D. Horner, Mr. Gorton, and

Dr. Darnford. Sixth, Mr. T. Lord, with Bright Eyes, Dr. Durnford, John Ashton, Mrs. Dodwell, Nora, and John Allen.

Class J.—Four dissimilar Alpines.—First, Mr. Beswick, with John Allen, John Ashton, Bright Eyes, and Dr. Durnford. Second, Mr. Buckley, with Bright Eyes, Dr. Knott, Dr. Durnford, and John Allen. Third, Mr. A. R. Brown, with Dr. Knott, Defiance, John Allen, and Unique. Fourth, Mr. R. Gorton, with Pluto and three seedlings. Fifth, Mr. Stelfox, with Bright Eyes, Dr. Knott, Dr. Durnford, and John Allen. Sixth, Mr. Lord, with Bright Eyes, John Ashton, Charles Turner, and John Allen.

Class K.—Pair of Alpines.—First, Mr. Bentley, with Dr. Durnford and C. W. Needham. Second, Mr. Stringer, with Forest Queen and John Allen. Third, Mr. Wood, with Emir and Bright Eyes. Fourth, Mr. Middleton, with Troubadour and Diadem.

Class L.—Single plants, yellow centres.—First, Mr. Lord, with John Allen. Second, Mr. Gorton, with Seedling 136. Third, fourth, and fifth, Mr. Stelfox, with Emir, Dr. Knott, Dr. Durnford. Sixth, Mr. Lord, with Bright Eyes.

Class M.—Single plants, white centres.—First, Mr. Beswick, with Seedling 117. Second, Mr. Lees, with Seedling. Third, Mr. T. Lord, with Exonian. Fourth, Mr. Beswick, with Henry Pomroy. Fifth, Mr. Brown, with John Ashton. Sixth, Mr. Beswick, with Countess.

Best Alpine in the show, Richard Gorton, shown by Mr. J. Beswick.

POLYANTHUSES.

Class N.—Three dissimilar, black grounds.—First, Mr. Thornley, with Cheshire Favourite, Exile, and Mrs. Brownhill. Second, Mr. Beswick, with Cheshire Favourite, Exile, and Mrs. Brownhill. Third, Mr. Stringer, with Lancashire Hero, Cheshire Favourite, and Mrs. Brownhill.

Class O.—Three dissimilar, red grounds.—First, Mr. Beswick, with Lancer, Middleton Favourite, and George IV. Second, Mr. Thornley, with Sidney Smith, Middleton Favourite, and George IV. Third, Mr. Stringer, with Sidney Smith, Middleton Favourite, and George IV.

Class P.—Single plants, black grounds.—First, Mr. Stringer, with Mrs. Brownhill. Second, Mr. Greenhalgh, with Cheshire Favourite. Third, Mr. Prescott, with Seedling. Fourth, Mr. Beswick, with Exile. Fifth, Mr. Beswick, with Lancashire Hero.

Class Q.—Single plants, red grounds.—First and second, Mr. Thornley, with George IV. and Middleton Favourite. Third and fourth, Mr. Beswick, with Lancer and William IV. Fifth, Mr. Thornley, with Sidney Smith.

HARMFUL AND HARMLESS GARDEN MOTHS—3.

'Tis possible that I may at some time or other have remarked in these columns that the name of "hawk moths" does not seem very suitable for the group of insects to which it belongs. They have not the ravenous qualities of the bird, nor its remarkably keen vision, and even the rapid fliers amongst these moths are scarcely hawk-like in movement. Peculiar, too, was another appellation given by the old entomologists; they called these moths (large and small) the Sphinxes—not because the insects presented a perplexing riddle, but on account of the attitude of repose assumed by certain of the caterpillars, which they fancied had a resemblance to the famous Egyptian Sphinx. It has been stated in several books that one of the local names for them is moth owlets, but I rather incline to think that belongs to some of the furry, greyish, slow-moving moths of the Bombyx tribe which occur about gardens at dusk. Possibly the larger hawk moths, such as the unicorn or Convolvulus and the Privet species, might a little distance off be mistaken for diminutive bats.

Unlike the death's head moth the Convolvulus Sphinx has a remarkably long tongue, which, even when flying, it stretches out, and thus suggested its other name, but of course it is also the possessor of two proper horns or antennæ. In gardens its special attraction is said to be the flowers of the Petunia, beside which many an entomologist has patiently watched in vain, for the insect is generally rare, though some seasons specimens appear all over the country. It is one of those species of moths which have been thought to be more numerous every seven years, but about this there is a doubt. A large and handsome moth; though not very brightly coloured in the wings, the body is conspicuous.

A friend tells us that one morning an old lady he knew was startled to discover a specimen in repose upon her doormat. She did not venture to approach it, so slipping out the back way she called in some neighbours, and they stood round it with curiosity or fear. Her cat had joined the party, and as the moth quivered its wings slightly, puss clapped her paw upon it, and thus ended their perplexity. The caterpillar, presumably a feeder by night, is seldom seen; it occurs on both the wild and garden Convolvulus during summer, also it is stated sometimes to eat the leaves of Balsams.

Most gardeners have seen upon the Privet hedges in August or September the caterpillars of the Privet hawk (Sphinx Ligustri), which, when nearly adult, is notable by its showy stripes of white and violet upon a light green ground. Perhaps it is for this reason that this caterpillar is chiefly visible early in the morning, and at

dusk, retiring during the day to the interior of the bush. I fancy some birds may attack and carry it off, but the cockney sparrow, I believe, lets it alone; for about London, especially in the West, it was till recently common on the hedges. The moth flies just at the season when the Privet comes into bloom. It is scarcely to be called a disfiguring caterpillar, though, from its size, rather voracious, and so the effects of its jaws are discernible on the twigs. Occasionally this caterpillar eats Lilac for a change, and I have found it upon the Plum. May or June often exhibits to us a sample of the Poplar hawk (*Smerinthus Populi*) resting on a paling or tree trunk quietly, with the greyish wings partially folded. Not till sunset does the moth rouse itself for an aerial excursion, not usually to any great distance. The caterpillar is greenish yellow, having a yellow horn, and feeds high up, often upon various Poplars; also, it is said by Newman to be found some seasons upon the common Laurel, and the Laurustinus.

Its near relative, the eyed hawk (*S. ocellatus*), thus named from the beautiful eye-like spots of black and white on the rosy red hind wings, comes to the garden sweets of May; as caterpillar it has probably lived not far off upon a Willow or Poplar. We have the species placed, however, upon the list of the foes of fruit trees, and I have several times taken caterpillars off the Apple, and they have been noticed upon the Peach; but their preference is not for these, nor are they numerous enough to be harmful. This is a whitish green, rough caterpillar with a blue horn, which distinguishes it from the kindred species. A brisk autumn wind occasionally blows down to a garden path a Lime hawk caterpillar, remarkable for having not only a horn like its brethren, but a curious plate or scale at the tail end of the body. Frequently it feeds on tall Elms, hence its sudden downfall. The moth is darker than the preceding, and rather less in size.

A lady friend discovered upon the Vines in her conservatory, a few years since, some caterpillars of the elephant hawk (*Chærocampa Elpenor*); it is not often taken under glass, but has also been noticed on Fuchsias. In the country its usual food is the leaves of some Willow Herb or Bedstraw. Here we have an instance of eyes marking a caterpillar not a moth, as upon its brown or green sides are two dark spots, which have been taken for the actual eyes of the insect. The name "elephant," too, is really applicable to the caterpillar, because it has a habit of elongating and then shortening the front segments, which suggested a resemblance to an elephant's trunk. In France, however, the people call the caterpillars of this and other species "cochonnes," comparing them to the snout of a pig! Some of them produce strong winged moths of bright colours; one of the handsomest is the Oleander Sphinx, abundant in some parts of Asia and Africa, found occasionally on the Continent where the Oleander flourishes, and stragglers have crossed over to English gardens.

The humming bird hawk (*Macroglossa stellatarum*) is an insect which has attracted notice in many a garden, and is responsible for various statements in newspapers about the appearance of a "humming bird in England." No doubt there is a resemblance—the size, the attitude of the moth, its outspread tail, its hum, too; and there are countries where people call it the bird fly. But it lacks the brilliancy of hue which is characteristic of the exotic birds, or of most. A good old entomologist, given to florid language, thus apostrophises this lively moth—"What is this at our Jasmine, with brilliant eye, with outspread and parti-coloured tail, humming loudly, and though driven away, returning from the rising to the setting of the sun? It is the humming bird hawk; from January to December we have some flower welcome to her, and she is welcome, most welcome to us and ours." Here is a little exaggeration, for this moth is hardly out on the wing quite as long, though it is seen sometimes from spring to autumn, and has been taken in the winter months. Certainly it does come back repeatedly to a flower or a resting place from which it has been disturbed, and it is specially partial to Jessamine.

Coming to fragrant plants on window-sills this moth frequently passes through an open sash into some room, creating surprise by its erratic flight up to the ceiling and round the walls. The long tongue suggested the generic name, and the specific one reminds us that the caterpillar feeds upon starry-flowered plants—i.e., on some of the Bedstraws or Galiums. It has a horn, blue tipped with red, the green body marked with white lines and dots. Years ago I used to find this caterpillar along some of the banks among Fulham market gardens, which have now been swept away. The moth just described has two near relatives, also natives of Britain, but less common, which any gardener might excusably mistake for a large bee. Both have tufts of hair along the body, which the insects spread out when flying, and transparent wings, but the long tongue they extend in hovering over flowers is an implement no bee could rival. Hence they dart rapidly from one to another; if alarmed going at immense speed, and are difficult to capture. One of our species has a narrow border to the wings—this occurs

chiefly in the north, the other, with a broad border, haunts the south. They are partial to the open spaces in woods, and lanes near them, but sometimes they appear as visitors to gardens, tempted by their floral attractions.—ENTOMOLOGIST.

SARMIENTA REPENS.

THIS, "F. J. B.," is the sole representative of a Chilean genus of Gesneraceæ. It is a curious fact that many plants from Chili have pendulous flowers of a red or scarlet colour, such as *Lapageria rosea* and *Fuchsia*, and the one now referred to, which is represented in fig. 81, is no exception, the flowers being scarlet and pendulous. The stems are long and slender, straggling over the ground, and rooting at the nodes. The leaves are about half an inch long, ovate and fleshy, the upper surface dark green. The peduncles, which are about 1 inch in length, carry one flower, of which the sepals are very small and have many hairs on them. The tubular corolla is an inch long, constricted at the

FIG. 81.—SARMIENTA REPENS.

throat and spreading at the mouth. Two of the stamens are half an inch longer than the corolla, and when carrying their yellow anthers add largely to the beauty of the plant. *Sarmienta repens* does well in baskets in peat, sphagnum, and a few pieces of sandstone. Care must be taken not to overwater during the winter. Its graceful habit and beautifully coloured flowers should win for it more extensive cultivation.

THE FORMATION OF DEW.

THE following observations by Dr. J. G. McPherson, F.R.S.E., Lecturer on Meteorology in the University of St. Andrews, are cited from the "Wakefield Express":—"Until very recently the exact constitution of the nature and formation of dew was unknown even by scientific men. The opinion was generally held that if you sped through the glistening meadow on a summer evening, through the diamond drops sparkling in millions, you would get your boots or trousers moistened with dew. It was also believed that dew fell from the air upon the ground. Now in both cases the opinion is wrong, for it is not dew at all which was encountered in the meadow, and dew does not fall from the air. If you look into the garden on a dewy night—for there is such a thing as dew for all that—you will find some plants moist. Glistening drops appear on the Broccoli, but the Peas are dry. Place a hand-lantern below one of the healthiest Broccoli leaves, and you will find that the moisture is collected in clear drops along the edge of the leaf and at the end of the veins of the leaf. The leaf veins radiating from

the centre line of the surface have carried the moisture of the healthy plant to the edges to keep up plant circulation; and the drops you see are not dew drops, but the watery juices carried out by the energy of the healthy plant. For place the lantern under an unhealthy leaf, and you will find no drops; there is no circulating vitality in it. Again, examine grass blades, and you will find large drops near the tips of the blades, the rest of the blades being quite dry. The large drops seen on plants at night are falsely called dew; they are produced from the plants themselves as tokens of their active and healthy growth.

This can be demonstrated in more than one way. Remove a branch of Poppy and connect it by means of an indiarubber tube with a head of water of about 40 inches. After placing a glass receiver over it to prevent evaporation, leave it for three hours. Then you will find water has been freely excreted through the veins, resembling what were familiarly called "dew drops." If the water pressed into the leaf is coloured with aniline blue, the drops when they first appear are colourless, but before they grow to any size the blue appears, showing that little water was held in the veins. What, then, has been for centuries called dew is not dew at all, but the watery juices of the healthy plants.

But look over dead leaves on a dewy night, and you will see a fine pearly lustre—that is dew. Dead matter gets equally wet when equally exposed, and real dew is not so common as is generally supposed. On many nights on which grass gets wet no true dew is deposited on it, and on all nights, when growth is healthy, the exuded drops always appear before the true dew. The difference between the true and the false dew can easily be detected. The moisture exuded from the leaf veins of the grass—false dew—is always isolated at points situated near the tips of the blades, forming drops of some size; whereas true dew collects evenly all over the blades. A glance distinguishes the pearly lustre of the dewy film from the glistening diamond drops of the healthy plant's juices.

But whence comes the dew? It does not fall from the air. Whence comes it, then? We shall see. Ground a little below the surface is always warmer than the air over it. So long, then, as the surface of the ground is above the dew point vapour must rise and pass from the land into the air. The moist air so formed will mingle with the air above it, and its moisture will be condensed, forming dew wherever it comes into contact with a surface cooled below the dew point. In fact, dew rises from the ground.

Place some metal trays over the grass, the soil, and the road on dewy nights. You will generally find more moisture on the grass inside the trays than outside; you will always observe a deposit of dew inside the trays, even when there is none outside at all. This shows that far more vapour rises out of the ground during the night than condenses as dew on the grass and the objects.

Pieces of iron lying on grass are soon surrounded with richer grass, on account of the moisture which the cold metal attracts from the rising water-vapour. Travellers in Australia and South Africa state that they often found the under side of their waterproof bedding placed on the ground to be wet after camping out at night. That shows that even in dry countries vapour rises from the ground at night. I remember, when walking in the vicinity of Hexham with an acute observer, trained to farming, that, on my remarking that the farmers might to their profit remove the extraordinary quantity of small stones from the fields in order to give room for the growth of the grain, he shrewdly said, "These stones collect moisture from the ground; the soil is thin, with a gravelly subsoil, and unless the maximum amount of moisture is collected (which can only be done by allowing these stones to remain), there would be a very deficient crop. They must not therefore be removed."

Dew, then, rises from the ground. But how is the dew formed on bodies high up in the air? If the dew comes out of the ground, should it not be found on bodies only exposed to the earth? Now, dew does not rise in particles, as it was once considered to fall in particles like fine rain. It rises in vapour. Some is caught by what is on the surface of the earth, but the rest ascends in vapour form until it comes in contact with a much colder surface, to condense it into moisture. The vapour does not flow upwards in a uniform stream, but is mixed in the air by eddies and wind currents, and carried to bodies far from where it rose. In fact, dew may be deposited, even though the country for many miles all round is dry and incapable of yielding any vapour. In such cases the supply of vapour to form that dew would depend on the evaporation of the dew, and on what was wafted over by the winds.

But the most practically convincing proof of the rising of dew from the ground is in the form of hoar frost or frozen dew. If it has been a bright, clear, sunny day in January, with no snow on the ground, look over the garden, grass, and walks on the morning after the intense cold of the night; big leaves may be found scattered over the place. You see little or no hoar frost on the upper surface of the leaves, but turn up the surface next the earth, or the road, or the grass, and what will you see? You have only to handle the leaf in this way to be highly astonished. A thick, white coating of hoar frost, as thick as a layer of snow, is on the under surface. Leaf after leaf will present the same appearance. If a number of leaves have been overlapping each other, then there will be no coating of hoar frost under the top leaves; but when you reach the lowest layer, next the bare ground, you will find the hoar frost on the under surface of the leaves. Now, that is positive proof that the hoar frost has not fallen from the air, but has risen from the earth. And hoar frost is frozen dew.

Dew, then, mostly rises from the ground, and what used to be thought

dew is the active exudation of the healthy grass. These two facts are now established. Brilliant globules are produced by the vital action of the plant, showing life in one of the most charming forms in the phenomena of Nature.

THE YOUNG GARDENERS' DOMAIN.

AMARYLLIS.

THESE very useful bulbous plants are so rarely seen well grown that a few notes on their culture may prove helpful to some reader of the "Domain." Their true value is most appreciated when arranged for effect in a conservatory, although they are useful where cut blooms are in demand for decorative purposes. They can be grown so as to produce a succession of flowers for several months by starting the bulbs into growth at intervals of a few weeks. We grow them very successfully, having each season a magnificent display. Several bulbs have produced three flower spikes, carrying twenty-three individual flowers from one bulb. They are grown in a Peach house, where the temperature seems to suit them admirably.

After flowering we repot the bulbs every second year, removing all offsets, and shaking off the old soil. We use a compost of three parts good fibrous loam, one of leaf soil, and one of cow manure well dried and rubbed fine, with about one-fifth part of silver sand. The plants are potted firmly, shaded for a few days, and placed in gentle heat, where they are grown until they have finished their growth. They are watered regularly until the foliage shows signs of maturation, when water is gradually withheld. During the resting season the bulbs should be watered occasionally to prevent their shrivelling.

I think the best mode of propagation is by offsets, although plants may be raised from seed, and usually flower in about three years. A sharp look out is kept for insects, and any that may be detected are quickly destroyed.—J. F. D.

[Will our correspondent oblige by numbering his sheets? The plants referred to are no doubt Hippeastrums.]

VIOLET MARIE LOUISE.

THERE are few flowers that excel (in a combination of good qualities) this beautiful double Violet. They are handsome, and continue fresh and fragrant a considerable time after being picked. For buttonholes they are exceedingly valuable, and are much sought after by both sexes of our employers.

A small bunch kept in a room scents the air, which is very refreshing, but too much of the scent is not, I think, conducive to health. Speaking from experience, it has a tendency to cause headache. Nevertheless these Violets are extensively grown for their scent alone.

They are of easy culture, and produce abundance of blooms throughout the winter—a time when they are most appreciated. Judging from my experience frame rather than pot culture is the more profitable, though I admit when they are grown in pots in a house there is one advantage—in being accessible for picking from in severe frosty weather, when those in frames may be utterly unapproachable. The soil in the frames should be taken out to the depth of 4 feet, then leaves of the previous autumn's collecting trodden firmly in to within about 15 inches of the glass. On the bed should be placed 9 inches of a good compost of loam and well-decayed leaf mould in equal parts to receive the roots, planting generally being done about the last week in August. Before lifting the plants (presuming they have been planted out in the open for the summer) it is a good plan, unless rain has been plentiful, to give them a thorough soaking the day previous, as the soil is then not so liable to fall away from the roots, and flagging of the leaves is greatly diminished.

They should be planted about 8 inches asunder, making them firm and being careful not to bury the crowns too deeply, which I have noticed is a great drawback in several respects. Planting being finished the whole ought to be well watered, when the plants will soon commence flowering and continue throughout the winter. Should they show signs of red spider the foliage must be well syringed two or three times a day unless the sun is very hot.

The lights should be placed over them as soon as cold nights set in, always propping them up for the admission of air, except in case of severe frost, or the leaves will soon turn mouldy. They need picking over occasionally, as any decaying leaf soon contaminates those adjacent to it, and a mass of decay follows which is very detrimental.

For supplying the stock for the following year the strongest crowns ought to be selected and pegged into the soil, all others being cut away as they appear. An occasional supply of liquid manure suits them.—ASPIRANT.

THE MELON.

IF early fruits are desired sow one or two seeds in 3-inch pots about the middle of December. Use a loamy compost with a little leaf mould added. If the pots can be plunged in a hotbed until germination takes place so much the better. The temperature of the house should range from 65° to 70° by night and 70° to 75° by day. When the young seedlings appear take the pots from the plunging material, and arrange the plants as near the glass as possible, avoiding draughts. When nicely rooted place in 5-inch pots, using a compost as before, but rougher. Do not be too liberal with water, as the plants soon damp off if too much is given. The pots should be placed on a shelf about 1 foot from the glass to prevent the plants from becoming drawn. Aim at sturdy growth, and good results should follow.

Before the pots get too full of roots, if it is intended to plant them out in beds where bottom heat is at command, all should be in readiness for their reception. The compost, consisting of three parts good fibrous loam, one of manure, and a slight sprinkling of soot, should be placed in a ridge about 2 feet through, extending the length of the house. When it is well warmed through and the bottom heat ranges about 80° it will be suitable for the plants. If it is intended to fruit them in pots these should be 11 inches in diameter, clean, and well drained. The soil to be used for potting should be placed in the house several days before being required for use in order that it may be well warmed through. Pot firmly, allowing space for future top-dressings. Stand the pots on a warm surface if space for pinning is not at command. Allow a distance of about 2 feet 6 inches from plant to plant.

When planting in the ridges do not plant too deeply. A distance of from 2 feet to 2 feet 6 inches is sufficient for ridge-planting, according to the method of training the plants. Very little water will be required at first, and when afforded it should be clear, as in its early stages of growth the Melon does not relish stimulants.

Gardeners have different methods of training Melon plants, but I think what is known as the single cordon system is the simplest, and at the same time it affords the quickest results. This consists of allowing the plants to run about three parts the height of their allotted space before pinching the point out, and stopping all the side shoots at one leaf beyond where the female flower shows. If the growths be thought too close together do not hesitate in removing a few to prevent overcrowding of the leaves. It should be the object of the grower, by judicious pinching, to get three or four flowers open at once before fertilising. —SEMPER.

(To be continued.)

EARLY FRUIT HOUSES.

THIS is one of the most important features connected with gardening. If one has a collection of plants of any description that do not look quite happy, they can in most cases be restored to health in a comparatively short space of time by strict attention to their cultural requirements. But with a vinery or Peach house, where the crop has failed from any cause, it is very different, as we have to put up with an eyesore for the whole season. No one is so much annoyed at this as the man in charge of the houses, if he takes interest in his work. However, such cases as losing the whole crop are somewhat rare, although I have seen several in my experience; but poor and indifferent crops are frequently met with. There are various causes for these failures; sometimes they are of a puzzling nature, but generally the cause or causes are within the power of the gardener or man in charge.

Take the case of early vineries for instance. One hears some of the following reasons sometimes for indifferent crops:—1, I do not think the wood was sufficiently well ripened (matured is meant); last autumn was very wet. 2, They were overcropped last year. 3, I think they are wrong at the roots, and want replanting in a new border. Any of these reasons may or may not be the cause. The first one is doubtful, as early Vines ripen their fruit first, and the wood generally gets well matured if airing and stopping the growths are attended to. No. 2, Overcropping is not so often the case with early Vines as later ones, as most gardeners seem to realise that early Vines should have moderate crops. Mistakes in overcropping are sometimes made through size of bunches, a number of small bunches being very misleading, looking a heavy crop, whereas bunches from 2 lbs. upwards, if only one-third the number, form invariably the heavier crop.

We must be guided by circumstances about cropping, as the size of borders, number of rods, and condition of the Vines, whether strong and healthy, must be considered. The results may be seen more or less the same year, as the berries are smaller and not finished so well, growths not so vigorous, and the next year the Vines will not break so strongly as they might, nor will the bunches be so large as usual. No. 3, The last excuse finds favour with most gardeners, rightly so in many cases, although I have known instances where the roots were not at fault. Especially do I remember one case, where the border was well made with the best of soil, and was one mass of good active roots, and although the crop was light the berries shrank badly, which shows something beside plenty of roots is necessary to their well being. No doubt many have noticed that the treatment has been different where the borders have been remade. The vinery is looked after much better, the airing is more carefully done, the water is warmed when required, no cold draughts are allowed, and no plants permitted on the border for a time, and altogether this house receives more attention than any other. The Vines succeed under these conditions, but it is not all due to the fresh soil.

A great improvement may sometimes be brought about by stricter attention to various smaller items in Vine culture. Moisture both at the roots and about the house requires to be used by a thoughtful person, as too little or too much will bring about bad results. With early Vines much depends on the size of the borders, but if they are kept moist after the growths are well started nothing serious will occur. Damping down the house, if done at the proper time, helps very considerably towards the best results. The practice of standing rows of Beans, Tomatoes, or such-like plants, that require a large amount of water on the border, must be condemned, as it soddens the soil, and loss of roots occur.

Ventilation plays an important part in early houses, as much depends on the weather and situation. Knowledge on this subject is best gained by taking into consideration size of house, how situated, the mode of

ventilating, and by carefully watching the thermometer. Disbudding should be done as early as possible, and stopping must not be neglected, always remembering that large healthy foliage thinly distributed is much more beneficial to the Vines than runaway shoots. Thinning the bunches requires care, or defects in the crop will be very serious.

It is good policy to spare a little more time than is often allowed for the work in the fruit houses, as the value of good early Grapes, Peaches, and Melons is well known, and there is no doubt that success is gained more frequently when the work is done carefully and at the proper time. Failures are not always the gardener's fault, as sometimes the heating apparatus goes wrong; but the potting of a plant, for instance, if put off for a day is not so bad as neglecting the necessary work in an early fruit house or two.—J. L. G.

HARDY FRUIT GARDEN.

Mulching Strawberries.—Quarters of Strawberries in full bearing and older plants will now receive much benefit from a liberal dressing of farmyard manure spread between the rows. That containing a large proportion of strawy material is the best for present application. The soluble matter held by the decomposed or solid manure is washed into the soil among the roots, which quickly appropriate it. This leaves the undecomposed and strawy parts on the surface, and being washed clean by rains a suitable resting bed is formed for the fruit. The mulching, too, is serviceable in preventing evaporation from the soil and maintaining moisture about the fibrous roots abundantly present in the surface soil, where they have a natural tendency to ramify.

Young Strawberry Beds.—Beds planted early in autumn or late summer are showing flower trusses. If the plants were established sufficiently early and the flower trusses are strong a fair amount of fruit may be expected. Should, however, the plants be weak, it is not desirable that the flowers remain to develop. It is better to remove them, allowing all the energies of the plants to be concentrated in strengthening the crowns for the succeeding year; also cut off runners. Hoe the soil frequently to keep down weeds and promote growth. Later in the season mulch between the plants, though not so liberally as with old plants.

Disbudding Vines on Walls.—As soon as possible, when the Vines have produced growths, attend to the removal of such shoots which are likely to be superfluous or ill-placed. When spur-pruned, and the spurs are left long, there are usually more growths produced than room can be found for ultimately. As the principal leaves develop they demand a share of light. Rub off the least promising growths, preferably retaining those showing fruit and situated nearest to the main rods. Shoots starting from the old wood are usually unfruitful, and if not required for furnishing space or to lay in for producing new spurs the earlier they are dispensed with the better. Adopt the principle of disbudding gradually, so as not to provoke a check by the removal of large numbers of growths at one time. When in active growth an interval of a few days may only be allowed to intervene between the operations.

The attention required in disbudding gives an excellent opportunity to select well-placed shoots for training in. These are suitable for replacing older canes or exhausted spurs, and for furnishing vacancies with vigorous rods. Trained thinly and well ripened they bear fruit the following season. Lengths of 4 feet, however, are sufficiently long to retain under the most favourable conditions of maturing the wood.

Fruit Tree Enemies.—Difficult insects to destroy on fruit trees are the small caterpillars which are found enclosed in small webs, causing in many cases the leaves to adhere together or curl, so that they cannot properly develop. Owing to this, insecticides which may be applied cannot reach the pests. The best and most effectual remedy is hand-picking at the present time. Attacks may be prevented by dressing the branches and shoots with insecticides when in a dormant state. Apricots are attacked very frequently by a maggot which must be sought for in those leaves which are curled or rolled up, either crushing the larvæ with the thumb and finger or unfolding the leaves and picking them out. The points of shoots of cordon Apples are in some seasons infested with very small caterpillars, binding the tender young leaves together and feeding on the tissues. They should either be removed or crushed, as they frequently destroy the leading points.

Blistered Leaves.—The curled and blistered leaves met with on Peaches and Nectarines are due to the ravages of a fungus, *Exoascus deformans*, which luxuriates under conditions brought about by the exposure of the growths to the full effects of cold and bleak positions. The best immediate remedies to apply are the removal and burning of the affected leaves. Afford, if possible, temporary shelter from cutting east winds. In selecting a site for planting these fruits the necessity for a warm and sheltered position must be kept in view.

Aphides.—Aphides are of various colours, some being black or purple, some brown, and others green. All are pests of a troublesome character to fruit trees on walls, especially Peaches, Nectarines, Cherries

and Plums. If they appear on the shoots in the course of the present month exterminate them early. Syringing them with clean water is a ready means of dislodging the early colonies, also dusting with tobacco powder, but in very bad cases the use of insecticides in solution must be resorted to. A dry condition of the soil about the roots favours their establishment and increase, hence it is desirable that the rooting medium be kept properly moist. The present is a suitable time to give a copious watering, which will act beneficially in assisting the early stages of fruit development, and so invigorate the trees generally that they will not be readily subject to insects.

FRUIT FORCING.

Peaches and Nectarines.—*Earliest Forced Trees*—On the very early varieties the ripening fruit must be kept dry, also the foliage; but the border should not be allowed to become very dry, or it will act injuriously upon the growth and affect the formation and maturation of the buds for future bearing. As the fruit of the other varieties will not be ripe for some time keep the atmosphere moist by frequent sprinklings during the day, syringing in the morning and again when closing the house. The night temperature will be perfectly safe at 65° to 70°, but 5° less, though it will retard the ripening, will not tax the energies of the trees so much as the higher temperatures.

Fruit Stoning.—During this process the trees must not be hurried; 60° to 65° at night is ample, and 70° to 75° by day, avoiding high night temperatures and sudden fluctuations by carefully attending to ventilation. A little air admitted at night will prevent the deposition of moisture on the foliage through the night to any serious extent, and enlarge the openings when the sun acts on the house, yet without lowering the temperature, which should advance with the power of the sun and a corresponding increase of the ventilation. Avoid anything calculated to dry the atmosphere suddenly, such as fumigation and opening the ventilators widely after the sun has acted some time on the house, for the effect is to cripple the foliage, when the fruit from the check may be seriously imperilled and fall. Early closing is to some extent desirable, and an advantage in swelling the fruit to a good size, but it must not be continued too long. It is also advisable to allow a little extra latitude to the growth, but on no account permit foliage to be developed that must afterwards be removed in quantity. Keep the inside border well supplied with water, and avoid undue excitement at the roots by stimulating them with quickly acting nitrogenous manure in either solid or liquid form. Judicious feeding, however, is a great aid to trees when stoning; but let it be of a phosphatic, potassic, and magnesian nature. The surface may be mulched lightly to keep it moist and attract the roots.

Trees Swelling their Fruit.—These swell most at two periods—namely, after setting, until the commencement of stoning. The first is materially, if not entirely, influenced by the previous storing of matter in the trees and the available food in the soil; but a genial condition of the atmosphere accelerates the swelling of the fruits, and the means employed to secure a good root action, which is best effected by a judicious and gradual regulation of the growths by the process of disbudding and in thinning the fruits. Overcrowding is a great evil, but large reductions of foliage at one time as well as fruit are not good. There is no safety save in a steady progressive growth and careful disbudding. The more vigorous the trees the greater is the danger of the fruit being cast in stoning, and the evil is afterwards increased by severe disbudding, also by a close and moist atmosphere. In the last swelling after stoning tie the shoots down, so that the fruits may be fully exposed to light, but moderate extension of the growth will materially assist the fruit in swelling, care being taken that the principal foliage and fruits be not interfered with. Supply water thoroughly to inside borders when necessary, and liquid manure to weakly trees.

Vines.—*Early Forced.*—Where the Grapes are ripe fire heat will only be necessary to keep the temperature at about 60° at night, ventilating freely by day. Black Hamburg and other thin-skinned black Grapes will need slight shade, such as that of a double thickness of herring nets over the roof lights, and it will also prevent amber-coloured Grapes assuming a brownish hue, detracting from their appearance. Damp the house occasionally, not allowing moisture to be condensed on the berries, but prevent it by a little ventilation constantly, and insure its dissipation by increasing the amount early. A certain extent of air moisture is necessary for the foliage, and will not injure the Grapes provided the atmosphere is not stagnant. A moderate extension of the laterals is advisable, as it tends to keep the roots active and to prevent the premature ripening of the foliage, which must be kept clean and healthy as long as possible. If the principal leaves fall a prey to red spider, and there are no laterals to utilise the sap, it is probable that the axillary buds will be started prematurely. If fermenting materials have been applied to the border part of them should now be removed, leaving sufficient for a mulch, and if the roots are active in the lower part of the material a little fresh may be placed on the surface to protect them from the atmosphere and impart a neat appearance.

Early Muscats.—It is hardly possible, and certainly not desirable, to have Muscat of Alexandria ripe before June. Black Muscat (Muscat Hamburg) may be ripened by the end of April; but it sets its berries very indifferently at an early season, and fertilisation makes very little difference, as the pistillate parts of the flower are often devoid of ovules, and cannot possibly be set. Madresfield Court cannot be classed as a Muscat in the same sense as a Muscat of Alexandria, but it forces admirably, and has some Muscat flavour. Crops of Muscat of Alexandria

started in December are now ripening, and the Vines must not lack water at the roots. Examine the inside border every week, and if moisture be necessary give it, or liquid manure liberally and warm. The temperature should be kept at 65° to 70° at night, 70° to 75° by day artificially, and through the day at 80° to 90° from sun heat. A circulation of air should be kept constantly, warm and rather dry air being necessary to perfection in Muscats. If the sun is very powerful, and the panes of glass large and clear, a single thickness of herring nets drawn over the roof lights will break the force of the rays, preventing scorching of the leaves and berries, which is often occasioned by the deposition of moisture on them, and the latter is a common cause of spot.

Vines Started at the New Year.—The Grapes are colouring, and need a moderate amount of air moisture to swell well, damping the house two or three times a day until the colouring approaches completion, when a drier atmosphere will be advisable; but moisture must not be entirely withdrawn, or red spider will seriously damage the foliage, and premature ripening of the leaves will be induced, the Vines starting into growth when they should be going to rest. Afford free ventilation, having a little at the top of the house constantly; a circulation of warm air contributes to good finish and quality. Moisture at the roots must be furnished thoroughly, one good soaking of tepid liquid when the Grapes change colour and a mulch of partially decayed manure will generally secure sufficient moisture until the Grapes are ripe. The roots, however, must not lack moisture. Atmospheric moisture will not injure Grapes of this class (Hamburg and Sweetwater) at this time of year provided it is not stagnant and deposited on the berries, and this will not occur if the ventilation is properly attended to, and a gentle warmth is maintained in the hot-water pipes. Keep the night temperature at 65°, a little more on warm, and a few degrees less on cold nights, 70° to 75° by day, 80° to 90° with sun heat and full ventilation, closing at 80°, all but a small space at the top of the house.

Succession Houses.—The sun is an important factor in keeping down the bill for fuel. There is nothing like opening the ventilators early in the morning, admitting air in a safe quantity to pass through the house. It causes excessive moisture to disappear, allows the foliage and fruit to warm equally with the atmosphere, preventing scorching, while elaboration begins early, and is continued through the day. By closing early the crops are accelerated in swelling, provided there is a due supply of atmospheric moisture, which can be secured by damping the paths and borders at closing time. Before nightfall admit a little air at the top of the house. This chink for air saves Vines from scorching when the air-giver is not up early on sunny mornings, but the ventilation should be increased by the time the sun acts powerfully on the house. Thinning the berries must be attended to and followed up persistently. The morning and evening is the best time for operating, alike to cultivator and the Grapes. Remove all surplus bunches. Stop or remove laterals not required, letting those retained extend where space permits. Do not crowd the foliage, and never allow the laterals to interfere with the principal leaves, as these, to feed the buds at their base, require free exposure to light and air. Supply water or liquid manure to the borders liberally when needed, and encourage surface roots with top-dressings of superphosphate, fish meal, and blood manure. It is a good plan to mix all together with as much of the whole added of wood ashes, and sprinkle a handful (about 4 ozs.) on each square yard, washing in. Sulphate of ammonia assists Vines needing vigour. Nitrate of soda may be used where the soil is sandy or chalky, and nitrate of potash where that substance is deficient, an ounce per square yard being sufficient for one dressing. The night temperature should be kept at 60° to 65°, 70° to 75°, and 80° to 90° from sun heat.

Late Vines.—These are advanced for flowering, and the early started may be in bloom. When out allow a night temperature of 70°, and 80° by day, with a free circulation of air, but not a drying current, a genial atmosphere being maintained by damping the paths and borders. Brush the shy-setting varieties over with a camel's-hair brush, and fertilise the bunches carefully where there is a deficiency of pollen, taking it from those that afford it freely. Up to and after flowering the night temperature should be kept at 65°, 70° to 75° by day artificially, keeping at 80° to 85° or 90° through the day, with moderate ventilation in bright weather, and admit air when mild. Thin the bunches and berries, removing duplicate bunches unflinchingly, and reserve the most compact. The free-setting varieties should be commenced with first, leaving the shy-setting kinds until it can be seen which are the properly fertilised berries by their taking the lead in swelling. Forward Vines that have only been recently started, seeking advancement by sun heat, but allow a free circulation of air so as to insure sturdy growth and stout foliage.

PLANT HOUSES.

Richardias.—Plants that have flowered may be placed outside in a sheltered position for a few days and then planted out. Provide a well-manured trench for them, so that the base of the stem will be a little below the surface. Break up old balls at planting time, and divide so that they will not need disturbing when the lifting season arrives further than is necessary to reduce the balls to fit pots of serviceable sizes. Young stock that has been grown on may be planted out at once without disturbing the roots. If the weather continues dry give the plants a good soaking of water after they are planted out, and mulch the surface with manure or a mixture of leaves and manure that has been used for hotbeds.

Eupatoriums.—Exhausted specimens may be cut back closely if larger plants are needed another season. When they have commenced growth partially reduce their roots and replot them. Start them in

frames until they are growing and rooting freely, when they can be hardened and planted outside or placed into larger pots and plunged in an open sunny position. Where plants are needed in 6 and 7-inch pots insert cuttings at once. They root quickly in hand-lights in ainery or similar structure. Directly they are rooted pot singly and place the plants in a cool frame, and finally outside.

Chrysanthemums.—Those that are being grown on the single-stem principle are becoming too tall for frames. Harden them and place them outside in a sheltered position. As they are placed out supply each plant with a stake, for strong winds and heavy rains may break them. If these plants have been in 6-inch pots for some time and are well rooted place them into their largest pots, but be careful not to overwater them. Those that were rooted later may still have the protection of frames, but give them abundance of air to prevent their drawing up weakly. The object to be aimed at is a firm sturdy growth. Gradually harden those that are still in small pots, so that they can be placed outside as they are potted. In potting be careful that the soil is in a suitable condition for moisture. If wet the plants seldom succeed satisfactorily afterwards. Water carefully and syringe freely. Remove the laterals from the axils of the leaves as they appear from those that are grown for the production of large blooms. Some of the earliest plants will show signs of branching near the top; help them out of this condition by pinching the shoots to a lateral that is showing prominently. Early flowering varieties may be allowed to branch in a natural manner, when the required number of shoots for leading upwards may be selected and the remainder removed, the necessary supply of stakes being collected together in readiness.

Ivy-leaved Pelargoniums.—Plants that are rooted for autumn and winter flowering may be potted singly in 8-inch pots. When they are rooting freely place them in cool frames to induce sturdy growth. Cuttings may still be rooted, and the plants will be useful for winter flowering. At this season these should be rooted singly in small pots, so that they can be repotted without checking them.

Zonal Varieties.—Cuttings may still be rooted in quantity for winter flowering on the same principle as advised for Ivy-leaved varieties. Those well rooted in 3-inch pots may be pinched and placed into 6-inch pots. Press the soil firmly into the pots, and use a compost of loam, one-seventh of manure and sand. Place the plants as they are potted into cold frames; keep them close for a time until they are rooting freely, when they may be hardened and stood in a sunny place outside.

French and Fancy Varieties.—Give those that are throwing up their flower trusses liquid manure in a weak state every time they need water. Soot water is very stimulating to these plants, and acts quickly. A suitable artificial manure applied to the surface of the soil is the safest and quickest method of feeding these plants. Keep later plants perfectly cool and give them abundance of air. The closer the glass these plants can be kept and the more air admitted the sturdier they grow and the finer are their flowers. Plants that were rooted late and are weak and puny in appearance will, if well cared for, make grand early flowering plants for another year. Those that some would throw away have a good start of cuttings inserted even now, and will, with care and proper treatment, make plants 2 feet through them by next spring. Stop the shoots until the plants are well established in 4 or 5-inch pots, then allow them to grow, without pinching, outside, keeping them somewhat dry until the middle of July, when they may be partially shortened back, and when they have broken into growth potted and kept growing on. These plants may be pinched once afterwards and placed in their largest pots early in January and allowed to lengthen out their shoots and flower. They should never be really dried up. Old stool plants may be cut up for cuttings; insert wood that has a moderate amount of firmness about it. Wood of this nature soon roots, and plants of a large size may be produced for early flowering next spring.

find them much weaker than they expected. This is not owing to any fault in management, but may be put down solely to the weather. In South Yorkshire there have not been more than three days during the past month in which the bees have been able to go any distance from their hives. This is tantalising to the bee-keeper, who has had to supply his bees artificially with what could have been obtained naturally if the weather had been favourable.

TWO QUEENS IN A HIVE.

This is not an impossibility, though uncommon. I do not refer to the double-queened hive, in which there is a division board to keep the bees separate in the brood nest, although the workers amalgamate in the supers, but when treated in this manner it is two stocks pure and simple. I allude to an ordinary single colony, at the entrance of which a queen was observed to be balled, on one of the few fine days experienced a fortnight ago. She was at once liberated, but was again balled by the bees. As this was an unusual occurrence so early in the season, she was placed in a box, and the colony examined. It was a strong stock with brood in various stages of development, and as I expected, a queen was found on one of the combs. Before examining them I was convinced such was the case, for had they not a queen, and no means of raising one, the bees would joyfully have accepted a queen from whatever source she came, and would not have balled her at the entrance.

But where did the strange queen come from? Was she turned out of the hive on the floor board of which she was found, or had she come with a starvation swarm which had been tempted to leave their home whilst the sun was shining brightly, and had joined the inmates of the hive in which she was found? Such, I believe, was the true history of the case. The rightful owners would accept the workers, but not the queen, who was seized and balled before she could gain admittance. This I consider is the correct theory, as I afterwards introduced her to a colony which had not a satisfactory queen, and which has since been fed with warm syrup daily. She has filled several frames with brood, and is an active prolific queen. The queen, too, in the stock in which she was found is equally prolific, being a young one hatched in June of last year.—AN ENGLISH BEE-KEEPER.

350 LBS. OF HONEY FROM ONE HIVE.

I FANCY I am able to throw the searchlight of the destructive criticism upon the extraordinary yield of honey commented on by your correspondents. The paragraph went the round of the Scotch papers uncontradicted, but it had arisen from the ignorance of a reporter. The amount of honey (350 lbs.) was not taken from a single hive, but was taken off in a week by the owner of an apiary of some twenty hives, who, being one of those bee-keepers who cannot resist the opportunity of making their fellows turn green with envy, suffered the statement to be spread abroad unchecked, although, doubtless, he chuckled over the reporter's stupidity in secret. I am able to say these things with certainty, as the incident occurred quite in my own neighbourhood, and also to certify that it was the occasion of much merriment among all those who knew the true circumstances of the case, and who know too well that such a phenomenal yield is beyond even the fondest dreams of an enthusiast.—A BORDER BEE-KEEPER.

CLEANSING COMBS.

I SHOULD be glad to know the best way to purify or disinfect combs in a bar-frame hive in readiness for the coming season, from which stocks have died.—R. T. W.

[If the bees died owing to shortness of stores or from queenlessness, and the combs are clean, they may again be used with advantage. They will probably have a small quantity of dry pollen in the cells, which the bees will remove with impunity. But if the dry pollen is extensive, which is often the case when the bees have died early the previous autumn, it will save the bees a great amount of labour if the combs are cut down to the midrib, and the whole of the pollen removed. The bees will then make new cells on the old foundation, which may again be used for breeding or extracting purposes.]

They are not difficult to manipulate; a knife with a fairly long blade is best for the purpose, and with a little practice the work may be done without injury to the combs, and does not necessitate melting them down. In my own apiary I annually examine all spare combs. Those that are old and discoloured are placed on one side for the melting pot, whilst others that are of good colour and otherwise suitable are treated as above. This plan has the advantage of keeping all combs in stock in good condition.

Is "R. T. W." quite sure that the stocks which died were healthy and free from disease? as that dread pest of bee-keepers, foul brood, is prevalent in some parts of the country, and as it is very infectious great care should be taken in a district where it is known to exist. It is much more common in the South than the North of England.

THE BEE-KEEPER.

SEASONABLE NOTES.

BEE-KEEPERS probably observe the changes in the weather more than the majority of people, as it has an important bearing on successful bee-keeping. Arrangements must be made beforehand, but if the weather is unfavourable the best laid plans will often go astray. How often one hears the remark, "If the weather had been warm and bright what a grand harvest of honey I should have had, instead of which I have to feed my bees to prevent them starving."

It is yet too soon to speak with any certainty as to what the present season will be, but up to the end of April, with four months of the year gone, the outlook is certainly not promising, from a bee-keeper's point of view. We shall have to go back several years to find a spring in which the bees have done so badly. The first few days of April were heralded in with snow, hail, and rain, accompanied by cold north or east wind, and this has continued throughout the month. Bees have made little headway, the brood nest has been contracted, and bee-keepers who expected to have their bees at the swarming point at this date will probably

If the bees died from any disease I would recommend the combs to be melted down, and the frames destroyed. They may, however, be used again if placed in boiling water for a short time, and afterwards cleansed with carbolic acid; but as they may now be obtained so cheaply they are really not worth the trouble and risk. The hives, too, should be well scrubbed with hot water, and afterwards painted inside and out with strong carbolic, which will destroy all the germs of disease. Hives and frames treated in this manner should afterwards be placed in the open air for a few days before being used, otherwise there may be a difficulty in getting the bees to remain in the hive owing to the unpleasant odour. If the bees died from an infectious disease the combs cannot be purified, and if there is the least doubt in the matter it is better to err on the safe side. But with hives and frames it is quite different, for if they are carefully disinfected they may again be used without danger, as shown above. If in doubt write again. — AN ENGLISH BEE-KEEPER.]

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, London, S.W. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects, through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Gold-laced Primrose (J. F. S.).—There is no doubt a tendency to lacing in the flowers, but the colours lack definition. It is not unlikely that when your plant gains strength it will develop into the Polyanthus form of flowering, but whether it does so or not the variety possesses no commercial value.

Origin of Vegetables (Lecturer).—We cannot tell you what you desire to know. The information could only be acquired by laborious research; but the following records may not be without interest, as bearing on the subject of your note:—"Old Vegetables."—Of vegetables known in very remote times, the Onion is the most conspicuous. As late back as 2000 B.C. it was a great favourite with the Egyptians, and we read, in Herodotus, that there was an inscription upon the great pyramid setting forth the fact that 1600 labourers had been supplied with Onions in one day. Another plant eaten in times almost as remote is the Pea, which has been found in the lake dwellings of Switzerland, inhabited during the ages of stone and bronze. It was well known to Romans, fried Peas being sold during the performances at their theatres. When the Pea was first introduced into England we do not know, but old chronicles make mention of the fact that Green Peas were eaten in the monasteries soon after the Norman Conquest. The Romans, by-the-by, always ate theirs dried. Peas were a great luxury during the reign of Queen Elizabeth, and were eaten with the 'cods' on, when young. At the time of Charles II. they were so dear as to cost £1 a pottle. The Cabbage is but a variant of the common yellow-flowered Cabbage of our seashores. We know this from the fact that the red pickling Cabbage reverts to that ancestral form after a few generations of neglect. This sea Cabbage is also the parent of the Cauliflower, the Broccoli, and the Kale, which parentage the Romans appear to have been aware of, as they always manured their Cabbage gardens with seaweed. The largest plants that they raised were of the kind called Sabellian, one specimen of which is mentioned by Pliny, as having been 3 feet across. Asparagus was sucked by wealthy gourmands more than 200 years before the Christian era. Even the stern Cato was extremely fond of it, and declared that he once cultivated three large heads, whose united weight amounted to the equivalent of an English pound. If one wishes to enjoy a surfeit of the delicacy, let him go to the salt steppes of Northern Russia. Here miles on miles are covered with the heads, upon which horses and cattle feed, eating them like grass. Artichokes, of the kind known as Jerusalem, are mentioned by Dioscorides as having

been eaten during the first century B.C. The Beetroot, the Parsnip, and the Carrot were all Latin vegetables, but of the first only the leaves were eaten before modern times. The first Parsnips we hear of were brought to Rome from Germany, and were served at the table of the Emperor Tiberias, who ate them with honey. They were known to the Anglo-Saxons, who called them 'mad napes,' because eating them when old was supposed to unsettle the reason. The Carrot is mentioned by Theophrastus in his 'History of Plants,' as having been first obtained from Sparta. It was brought to this country by the Flemings. Though our market gardeners have made many attempts to raise the Sweet Carrot from the wild stock, they have all been unsuccessful."

Cucumber Plant (and Soil (A. G. W.).—The sturdy short-jointed stem and thick leathery leaves of the plant are all that could be desired; but the fruit is stunted and curled. There, however, was no disease in the fruit, nor could we find any parasitic organism on any part of the plant above ground. But if the parts in sight were normal, there was something out of sight to the ordinary vision—serious, meaning loss of crop, capital, time, and labour; and we sincerely sympathise with you in your misfortune. This, however, goes but a very little way in anything connected with parasitism, and to find methods of relief the nature of the evil must be traced to its source. Quite healthy to the collar, or where the seed leaves had been, was your plant in the part above ground. On making a transverse section of the stem just below the seed leaves, and on the part that had been in the soil, and holding this up to the light, the woody tissue was found to be slightly brown. Making a longitudinal section, and placing this under the microscope, the hypha of a fungus was plainly visible in the intercellular spaces of the vascular cells, and on two sides the mycelial hyphae had broken through the cellular tissue, and appeared outside the stem. Every endeavour was made to find "fruits" of the fungus, but without success. The mycelial hyphae (web) was that of the smother fungus, *Sclerotinia sclerotiorum*, Mass., of which the conidial condition is frequently suppressed. Following the root stem downwards the discoloration increased in intensity, till culminating in the decayed portion, which, as you say, is at the bottom of the root stem, between the stem and tap root. There the root stem was completely decayed and relatively dry, for this is not a wet rot, and the decay proceeded both downward and upward, chiefly the latter, in the root stem. In this dead part were numerous sclerotia (small black elongated bodies), the resting stage of the fungus, and from which spring the ascophores, bearing the spores of the parasite. Other portions of the roots were decayed, but they only contained mycelium. In other respects the roots and root stem were singularly healthy, and without nodosities, as caused by eelworm; nor were any of these pests found in the living tissues of the roots, but a portion of the decaying stem in a solution of aniline yielded a specimen of the short blunt-ended eelworm (*Tylenchus obtusus*, Bastian). The eelworm was certainly not the cause of the disease. Hyphae of the fungus in the woody tissues, in which the sap ascends, had partially cut off the supply of nutriment, and the fruit, instead of elongating, curled as a natural consequence. The case is what is known to gardeners as root (not collar) canker. The fungoid attack begins on the radicle or tap root. Sometimes it kills the young plants, and they become mouldy. That mould is the conidial condition of the parasite, *Botrytis cinerea sclerotiphila*, Sacc.; yours is simply this, suppressed as before stated, and it also produces a sclerotium, once called *Sclerotium durum*. This we have detected in Cucumber and Tomato seed, and is discernible by the black colour of the seed integument, therefore the malady may go over with the seed. This shows the importance of careful seed saving from only healthy plants. But the parasite usually goes over from year to year in the soil, and has done so in your case, as the roots are infested here and there on the lateral ones at a considerable distance from the radicle, and besides the soil contains sclerotia. You ask for a remedy and prevention in the future. The soil is good turfy loam, full of fibre—a very excellent one for Cucumbers, but it contains both eelworms and the sclerotia of the smother fungus. You may not appreciate our recommendation, as cultivators have an abhorrence of whatever tends to reduce the stores of nitrogen, but we must say that the soil needs, and must have, lime—not magnesian, but best chalk or land lime—and it should be mixed with the soil some time in advance of using it for Cucumbers, so as to part with its causticity and act on the organic matter effectively. In bad cases 10 per cent. may be used, then let lie six months; if 5 per cent., three months; but in most cases 2½ per cent. suffices, and this allows of the soil being used shortly after mixing. On the plants as they are we should not hesitate to place soil around the collar and get roots from the stem, mixing a little air-slaked chalk lime with the old soil without disturbing the surface much, adding some to the fresh soil, or some mineral superphosphate, 37 to 39 per cent. soluble phosphate, three parts; muriate of potash, 85 per cent. purity, two parts; and sulphate of magnesia, one part, mixed, using about 2 ozs. per square yard every fortnight or three weeks, and washing in. To get at the fungus you may use Little's soluble phenyle, one in ninety-six parts water, or 1 gill (¼ pint) to 3 gallons of soft water, which will give value for outlay as a manure, besides possibly killing both the fungus and the eelworm, using it in about the same amount as in an ordinary watering, and repeating occasionally. Some consider this sufficient without using lime, as it acts on the organic matter in the soil, and the plants give quicker and heavier returns. Nitrate of soda has also been used effectively in the ordinary course of watering, but not stronger than ½ oz. to a gallon of water, prepared a short time before used so as to become aired.

Cucumbers Gunned (Juno).—The Cucumbers are not infested by any disease, but are suffering from what is known as extravasated sap, due to excessive vigour, for which we do not know of anything more likely to afford relief than allowing a freer growth of foliage and keeping the atmosphere more evenly moist, also the temperature rather warmer. Only sufficient water should be given at the roots to keep the plants from flagging, but this must penetrate to the drainage, then with the atmosphere not excessively surcharged with moisture, and sudden depressions or fluctuations of temperature avoided, the fruit will swell freely. You may use equal parts by weight of air-slaked chalk lime and soot by measure, applying about 3 ozs. per square yard at intervals of a fortnight or three weeks, covering or mixing with a little soil so as to prevent loss of ammonia. A brisk heat and genial atmosphere, however, are the chief factors in inducing the fruits to develop. Are you certain that the soil at the base of the bed is not dry? If it is while most near the surface the fruits will swell so far and no farther.

Holly Trees and their Requirements (W. W.).—The common Holly (*Ilex aquifolium*) is a native of this country, Europe, and West Asia, and grows in a great variety of soils and situations. We have seen very fine trees of it on sandy loam of the new red sandstone formation, on strong clayey loam of the drift, on gravelly loam of the oolite, and on peaty soil overlying lias. We found the grandest specimen in somewhat shaded places on the slopes of a valley, the soil being a rather strong gravelly loam incumbent on freestone rock. It appears to like a generous soil, but absolutely free from stagnant water, while in very dry soil it is apt to lose its leaves. This may to a certain extent be counteracted by supplying manure, so as to render the soil more moisture-holding, and afford nutrition. We have supplied unhealthy trees with liquid manure from a farmyard tank after cutting their heads into form at the end of April, a dish of soil being formed about 1 foot outside the radius of the cut-back head, and 4 gallons of the liquid applied per square yard. The liquid manure was given during May, June, and July, at intervals of about three weeks. In two or three years the trees were pictures of health and beauty. Thus it was lack of nutrition in that case from which the Hollies suffered. On a similar soil, about 4 feet deep overlying chalk, Hollies grew into timber-like trees, 30 to 40 feet in height, remarkably profuse in foliage of a deep green colour, and persistent in retaining it. Indeed, it was a Holly soil, yielding what this plant requires, as shown by its ash constituents:—

Potash (KO)	19.16
Soda (NaO)	5.08
Lime (CaO)	35.68
Magnesia (MgO)	20.58
Iron (Fe ₂ O ₃)	0.85
Phosphoric acid (PO ₅)	5.03
Sulphuric acid (SO ₃)	1.03
Silica (SiO ₂)	7.86
Chlorine (Cl)	0.24

The chief mineral elements required are, therefore, lime, magnesia, potash, and silica, and it is likely that your soil may be deficient in lime. Where Hollies did not grow well we added some old mortar rubbish, and a good dressing of manure, trenching the ground about 2 feet deep, mixing the whole well together, and the plants did well afterwards. But most good soils will grow Hollies, the common species being found on nearly all soils, and its innumerable varieties are well known and extensively cultivated. It submits to almost any amount of pruning, but this should be practised either in September or in April, both in the case of trained trees and the clipping of hedges. Transplanting is best done at the beginning of May or early in autumn, when there is sufficient time for new roots to be formed before winter. It does not transplant well when old, and trees of large size had from nurseries require frequent removal to enable their safe transplantation. For fences, young plants are best, or even seedlings, but these take eight or ten years to make a fence 4 feet high. It pays to have the ground trenched to the depth of 2 feet, and about 3 feet in width, incorporating a quantity of manure with it at the same time. This is best done some time previously, say in autumn, as it gives time for the loosened and up-turned soil to get mellowed and sweetened, as also for the manure to become decomposed; but it should be considerably decayed when used. The soil will then be in good order for planting in May. As for Hollies growing well on an old battle field of Cromwell's there may be something in the bones of ancient warriors supplying phosphate of lime, but on his great field—Marston Moor—there is nothing very remarkable in the way of Hollies or other trees, yet the Nidd valley is remarkably good land.

Names of Fruits.—Notice.—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the

first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (G. G.).—1, Bramley's Seedling; 2, Northern Greening, 3, unknown; 4, Catillac. (D. S.).—1, Beurre Rance; 2, Moss's Incomparable; 3, Northern Greening. (R. D. J.).—1, Easter Beurre; 2, Catillac. (N. N.).—The Apple is Scarlet Leadington, an old and valued Scottish Apple possessing much of the character of the ancient Catshead.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, at being often difficult to separate them when the paper is damp. (S. P. T.).—*Cerasus* (Prunus) Padus. (A. L. K.).—*Prunus nana*. (S. H.).—*Iberis correaefolia*. (C. A.).—1, *Doronicum plantagineum excelsum*; 2, *Begonia metallica*; 3, *Lycium europæum*. (Inquirer).—*Dendrobium chrysotoxum*. (C. C. S.).—1, *Phlox setacea*; 2, *Spiræa hypericifolia*; 3, *Spergularia marina*; 4, *Genista racemosus*.

“TILL THE DOCTOR COMES.”

THIS was the title of a most excellent little book we once met with years ago. It was what one might call “a first aid.” There is with even the best informed so much ignorance about the symptoms of common diseases, and in accidents it is so easy to lose one's wits altogether, that a book of this kind is most useful,

Mind, when the doctor has been and given his orders the book should be put away; two authorities, however good, should not be consulted at once, and the living man is better than the printed words. Circumstances have led us the last week or two to consider (practically) the complaints animals of the farm are most liable to.

We live many weary miles from a good "Vet.," and horses especially are often quickly ill, and unless promptly treated soon succumb. As a rule the foreman has some rude knowledge of horse physic, and may often be trusted to doctor an old cow; but the best of them work much by rule of thumb, and pin all their faith (and the measure of that faith is great) on some well-advertised nostrum, which, if not actively harmful, is likely to do little or no good, costs money, and is the cause of waste of valuable time. It is so common to hear a man say he will try such and such a remedy, because he has "heard tell on it doing a sight o' good to Tom Smith's auld meer, or that it browt roond Bessie Lane's, coo that was a sight warse nor this un." In all probability the cases were not a bit similar. The man tries his hand, finds the patient does not improve, and then grudgingly sends for the farrier.

One of our greatest veterinary surgeons, till quite lately the head of his profession in England, we mean Professor Brown, has been alive to all this, and in a carefully written paper gives many practical hints, most valuable as coming from a man of his standing.

The first subject of which he treats is a wound. How dearly people love ointments, plasters, and "messments" of various sorts is seen every day. They are so anxious to assist Nature, and generally so irritate and aggravate the sore that it takes twice the proper time to heal. Banish all such rubbish from your drug cupboards. See that the wound is clean, free from dirt or other foreign matter, close it up carefully, cover with a little carbolised cotton wool. Nature will do the rest if you keep off germs from without. A horse is lame; do not bother to locate the trouble in the shoulder; look for it in the foot. Remember how much the foot is "put upon," so to say; think of the constant shoeing, sometimes by unskilful men; think of the wear and tear on the 'ard 'igh road.

If there is lameness in a fore leg (especially) remove the shoe and pare the hoof carefully, press with the pincers, and in all probability you will find an abscess, caused sometimes by a carelessly driven nail, at others from contact with a hard, sharp stone.

The matter must be got away by making a small opening, and after soaking the foot in hot water a dressing of tar and tow should be placed on the wound. The shoe should be lightly nailed on again.

The skin of the legs in badly regulated stables is subject to various disorders. Prevention being better than cure, we will mention the ailments, and then say how they may be avoided. Cracked heels and mud fever come first. Horses are brought in after their work oftener with wet legs than dry, plastered up with mud and clay and bits of grit. Wash is the axiom of the stable boy, the drying process he leaves to Nature. The washing is well enough, but takes too much natural heat out of the system if the horse has his own legs to dry. It is the standing quietly in the stable that does the harm. Wash, if you will, in a pond, and the cold water does not do the harm that the hot would, and the walk home after the bath assists the drying process. Hunters' legs are bandaged till the mud is dry enough of itself to brush out. We do not keep flannel bandages for cart horses, but hay bands are a cheap and handy substitute.

If there are cracked heels or mud fever exists, a remedy is found in a mixture of eight parts vaseline with one part of white lead or oxide of zinc.

A bruise freshly made, and before any swelling has come on, will be benefited by a cold lotion, but the application must be continuous. Where there is heat and inflammation hot fomentations are absolutely necessary. A bruised wound cannot heal

without first making some discharge. Carbolic acid and water make the safest and easiest of remedies; one part carbolic acid to a hundred parts of water.

Sprains are a very common source of lameness. Muscles, ligaments, and tendons are overstretched by violent movements, inflammation and swelling follow. A ligament or muscle once sprained is very liable again to give way, and one can hardly ever feel perfectly sure of absolute soundness in the limb affected. Cold water and rest will do wonders, but the cold water applications must be regular and frequent, and the rest long.

In some cases blistering becomes necessary. Then ointment of the biniodide of mercury is most useful, and here a farmer's doctoring must cease, as anything of firing or setoning is only to be left in the hands of a skilful operator; indeed, we hear much less nowadays of firing than we used to do say twenty years ago. There is material, and more than material for a paper on diseases of the digestive organs, which must be kept over for a future day.

WORK ON THE HOME FARM.

The Mangolds have not been drilled yet, as our field to be devoted to them lies somewhat low and near water, and is liable to suffer from May frosts. We once drilled Mangold in it in April; the plants came up quickly, but were killed by frost, except a few under the shade of some trees. We are steeping the seed to soften the husk, and shall now get it in at once.

The weather has been fine overhead, but very cold; nothing has grown much except Wheat, and that has had its exception, the best piece in the parish having begun to turn yellow. The fields which have not been too thick or forward are now beginning to look really well and decidedly promising.

Pastures are worse than ever, sheep are lower, the fairs have been disastrous, nothing but cattle nearly fit for the butcher meeting with anything like a ready sale. Potatoes are a little dearer, about 10s. per ton. We have, however, to be thankful for even that small mercy.

As regards farm work, we have brighter prospects to record. Much progress has been made with the working out and getting off of twitch. Fallows were less foul than we have seen them in most seasons, and although little or nothing but ploughing could be done to them in the autumn the task of cleaning has not been very formidable.

Twitch fires have been visible in all directions the last few days, and most fields are about ready for ploughing. If the weather should become very dry this will be most advantageous, for the absence of any necessity for further cleaning will enable us to keep the land quiet, and so retain its moist condition until Turnip sowing.

If the land be light and friable we would not move it at all after ploughing, but if it be rough and cloddy we would plough again in a fortnight and roll after the plough. In fact, for rough land the motto is, "Plough and roll," and if once is not enough "plough and roll again." The spring tooth cultivator is splendid for pulverising the soil, and on light and medium soils is a most valuable implement, but we cannot do without the plough yet.

We hear of serious loss of the Wheat plant where chilled ploughs were used for ploughing lea. This is the one operation they are quite unsuited for, and we have warned our readers against using them for the purpose.

REMARKS.

25th.—Generally sunny, but cloudy intervals.

26th.—Bright and mild throughout.

27th.—Sun visible through haze or slight fog almost all day, but no bright sunshine; thunder from 5.45 P.M. to 7 P.M., with spots of rain.

28th.—Foggy all morning, thick early, and yellow, with darkness, from 11 A.M. to noon. Rain from 7 A.M. to 9.30 A.M., and heavy rain at 8.30 P.M., other slight showers at times; generally sunny in afternoon.

29th.—Overcast till 9.30 A.M.; generally sunny after.

30th.—Sunny early, overcast from 10 A.M., steady rain from 1 P.M. to 5 P.M., and spots of rain in evening.

1st.—Brilliant early, and generally sunny all day.

Another average and unnoteworthy week, the storm on April 27th being of little moment, except in the South of London.—G. J. SYMONS.

Journal of Horticulture.

THURSDAY, MAY 13, 1897.

GRAPE THINNING. TEN COMMANDMENTS.

I RECENTLY received a copy of "Instructions for Thinning," printed for the guidance of those who use the scissors during the long Grape thinning time in one of the greatest commercial Grape-growing establishments in Britain. The trite remark of the sender, that they seemed to embody the "Ten Commandments in Grape Thinning," induced me to choose that sentence as a sub-heading for these notes. So good are the instructions referred to that I think they should be reproduced in the *Journal of Horticulture* for the benefit of the many readers who require definite information about this important operation connected with Grape growing. Below are the instructions, which all young gardeners should carefully read, and comprehend their significance.

INSTRUCTIONS FOR THINNING.

- 1, Take hold of the bottom of bunch with the left hand. Don't touch it anywhere else.
- 2, Begin thinning at the bottom and work upwards.
- 3, Take out all inside berries, cross berries, and small berries first.
- 4, The berries you leave should be the big ones that point straight out, and the berries that stand out most are best.
- 5, The berries should be left about three-quarters of an inch apart.
- 6, Don't rub the bunches with your head or anything else, because it injures the bloom on the berry and makes the Grapes look shiny when they are ripe.
- 7, Cut the stalks in close.
- 8, Keep your scissors clean; they will cut better.
- 9, Don't put your scissors through the bunch to thin the other side; you should move round the bunch.
- 10, Always thin the bunches with the biggest berries first.

It would, I think, be difficult to draw up a better code of rules for the guidance of those who work in market-growing establishments than the foregoing, but in private gardens, especially where exhibiting is practised, the aims of the cultivator are somewhat different. The market grower requires medium-sized compact bunches, the private grower a good supply of a similar type, but also a considerable number of large well-developed bunches to show what can be done by special culture. I propose, therefore, to enlarge upon the subject, as well as pen a few comments upon the market growers' instructions.

Rule 1 I do not quite agree with. When thinning a bunch which has not set well at the bottom it is a good plan to hold it by the point, as of course it must be removed when the bunch has been thinned. The same remark applies in cases where the terminal berry is so long that it requires removal to obtain a compact point, as few things look worse than to see the bottom berry hanging loosely when the Grapes are ripe. Those who wish to become expert Grape thinners should hold small and medium-sized bunches by the footstalk, just above the shoulder. With a little practice they will soon find it is not necessary to touch it with the hand in any other part. I have thinned thousands of bunches while holding them in that way, and although I do not wish to pose as an egotist I flatter myself I can thin Grapes as neatly and quickly as most experts. There are few gardening operations I like better, and many times I have spent fifteen hours a day at the actual thinning.

In dealing with large bunches it is necessary to use a stick about 8 inches in length, one end of it forked, as this is sometimes useful to hold up shoulders or steady the bunch, at others the straight end will be found the more convenient.

Rule 2 is definite and good—no one, I think, would take exception to it; 3 and 4 give important information, conveyed in such plain English that it would be difficult for anyone to mistake their meaning or err on the points treated of if the teaching is followed.

Rule 5 is, of course, only intended as a general instruction suitable for the majority of varieties. Such sorts as Gros Colman and Gros Maroc, when well grown, should be left $1\frac{1}{2}$ inch apart halfway up the bunch, a little closer at the points; and in the case of the last named variety about an inch apart on the shoulders, as the footstalks lengthen considerably there. It is seldom that Buckland Sweet-water requires any other thinning than that of removing the small berries, as the footstalks lengthen so greatly that it is often difficult to get a well filled bunch. Foster's Seedling, on the other hand, produces berries on short footstalks so freely that much careful thinning is needed; but they should seldom be thinned to more than three-quarters of an inch apart, as the berries are oval in shape and not of the largest size. Madresfield Court often produces very large berries, and though the footstalks are short they ought not to be left more than an inch apart on account of their shape; all berries in the centre of the bunch ought, however, to be removed. Black Hamburgs differ greatly in form of bunch. In some the footstalks are long, and the whole bunch is inclined to be loose; but little thinning is then required upon the shoulders, for although the berries drop when they begin to swell, as they increase in size they force each other upward, and in time quite fill out the shoulders. Other forms of Hamburgs are more compact in bunch, and therefore need thinning more freely, especially at the lower part.

Muscats ought not to be thinned till the berries commence swelling freely, those that fail to enlarge can then be removed, and where gaps occur the berries around ought to be left closer together, leaving them at an average distance of three-quarters of an inch apart. A few weeks later, if looked over again, the berries not required can be removed. Rules 6, 7, 8, 9, and 10 contain instructions which every Grape thinner should learn by heart and act upon.

In market-growing establishments the shoulders are invariably removed in order to secure compact examples, which travel well. No instructions on this point were therefore included in the printed form already dealt with, nor upon the management of large bunches for exhibition purposes. These are matters I will now deal with, as they require special treatment. Gros Guillaume I should say produces on an average larger bunches than any other Grape. These are often very handsome in shape, though frequently the largest clusters are somewhat loose and by no means shapely, but it is surprising how they may be gradually moulded into form by dexterous manipulation.

Before attempting to thin bunches of this description I always tie them out thoroughly, commencing at the top of the bunch.

The main shoulders have each in turn a piece of raffia fastened around the stem, taking care that the tie is loose enough to allow for the swelling of the stem; the shoulder is then drawn up to an horizontal position, and the other end of the grass fastened to the trellis on which the Vines are trained; a bow tie should be made, as throughout the growing season it is sometimes necessary to raise or lower the shoulders slightly. When the main shoulders have been treated in this way some of the larger branchlets which spring from them require ties too, so that the whole of the berries are evenly placed over the top of the bunch, right up to main stem. If the shoulders have long footstalks, and are consequently without berries for a couple of inches from their bases, they may be by exercising care and judgment crossed or coiled around the stem of the bunch, so that when the berries are of full size they will form a compact mass; in this way loose bunches may be converted into solid ones. I should have previously stated that large shoulders often need three supports, one near the point and the others equidistant from it, when the top of the bunch is completed. The smaller clusters beneath should be tied up to fill blanks and secure the desired shape. This done, little thinning is needed beyond taking out a berry here and there, also the very small ones.

Trebbiano requires the same treatment, with the exception that more thinning is usually needed than in the case of Gros Guillaume. Muscats and Foster's Seedling do not often require tying-out, but in some instances a distinct advantage is gained by doing so. When Black Hamburg and Muscat Hamburg produce large bunches it is generally necessary to resort to tying; on the other hand Black Alicante, Gros Colman, Lady Downe's, and other varieties with similarly stiff stems do not require artificial supports.

It should always be borne in mind that tying-out is done with the object of producing large bunches; if these are not required, severe thinning must be practised to put them into shape. Medium-sized bunches often have one good side shoulder. In most cases I remove these, but in some they are left, as they give the bunches the little extra weight needed to bring them up to exhibition size, and when well staged such bunches look well on the show boards.

Grape-thinning may to some seem tedious work, but I know full well there are thousands who find it a fascinating art; the latter will have fixed in their mind's eye the shape they wish each bunch to eventually assume, and by working on the lines above indicated will, I think, generally be able to closely approach, if not attain their ideal.—POMONA.

WILDERNESS GARDENING.

WOODS, copses, glades, and hedgerow banks have charms at all times to the lover of Nature. In the spring months the beauty of the "palms" (male catkins of the Goat Willow, *Salix caprea*), common Primrose, Sweet or even Dog Violet, Wood Anemone, Sweet Woodruff, strong smelling Bluebell or Wood Hyacinth with, in places, Daffodil, Forget-me-not, and Lily of the Valley, excite admiration when seen in Nature's profusion. Thus the wildlings of the hedgebank, copse, and wood may often be found in urban and suburban gardens, for it is not enough to cull flowers by the hand and armful, but roots must needs be borne off by basket and bagful as souvenirs of rural wanderings at holiday times. This, deplorable as it is in many cases, has led to spring flower gardening, for when the massing system came into force the common flowers of our gardens were almost wholly neglected, and but for their being cherished in old-fashioned and cottage gardens would have been lost.

The herbaceous border is but an outcome of collecting from various sources and many lands. The massing of flowers is the method of Nature, which affords a succession of beauty in different form and place throughout the season. Honeysuckles, wild Roses, and Clematis are no less charming than the earlier and more lowly spring flowers, and what more delightful than banks and mountains of "May?" while the Spiky Mullein and Foxglove, with purple and white masses of Willow Herb (*Epilobium*) yield to few pampered exotics in stateliness and charm during the summer.

In the autumn what excels in relish the self-picked Blackberry and the Hazel Nut? Where, in winter, have we such greenery as

in the Ivy and the brilliant hue in berries of the Holly? Nature is a continual feast—things of beauty are borne in her lap at all seasons, not in one place but in many, for does not the wet ground glow with the golden cups of the Marsh Marigold, the yellow-eyed blue Forget-me-not, and charming Orchis? Even the water bears its yellow and white Lilies, Arrow-heads, Bullrushes, and Reeds, with Violets and Soldiers, while high and dry hillsides are aglow with purple Heather, and on shady banks are graceful Ferns.

Pictures of Nature's profusion in towns are not uncommon. Many cottage gardens glow with Winter Aconite and Snowdrop, Primrose and Daffodil, Woodruff and Forget-me-not in spring time. Honeysuckle for sunny and Ivy for shaded places are the choicest of climbers, and in nooks and corners the Male and Lady Fern dwell in sweet harmony. Town gardens have their spring beds and borders, many of their occupants improved forms of native plants. Summer bedding gives place to winter, and in most gardens there is a bit of Nature—the pond of aquatics, the fernery, and the rockery for alpine. Then there is the shrubbery and lawn, a sort of modified wood, copse or glade, so that there is not much difference after all between an English woodland and a British garden in the natural. Indeed, it is but a miniature with the gems placed in the best setting, so as to accord with the refinements of the home.

But in the wilderness there is a sort of entire abandonment of culture and of trimness, which is really the measure of difference between the well-kept pleasure ground or flower garden. The wood, copse, and glade are improved by the introduction of hardy bulbs and plants, with climbers and trailers, as well as flowering shrubs or trees. The practice is very old—the true old English style, which has been at times overlooked, and to some extent over-run by the stiff and formal Dutch, but still the most satisfying, and returned to after a time, for it has the property of wearing well, and may be described as the supplanting of rubbish by "things of beauty" in their respective seasons. Such is the wilderness I have in view, not the blind following and imitation of Nature, but the introduction of plants that will increase in size, and form bolder groups as each year comes round, improving the scene and increasing the sources of pleasure.

First of all comes the glade, the ideal place for bulbs. Winter Aconites, Snowdrops, Crocuses, Daffodils, Snake's Head Lilies (*Fritillaria*), Dog's Tooth Violets, Grape Hyacinths, Squills, Solomon's Seal, Meadow Saffron, and no end of other things that never look half so well on bare ground as springing from grass. Bold irregular groups, broad in places, narrow in others; isolated knots, groups of these as if self-sown or Nature-planted, regard being had to height and harmony of colour, never losing sight of reserving plenty of setting or grass to alike show off the whole to advantage, and allow of walking amongst them.

Meadow Orchis, dotted here and there with English Iris, yellow Allium, blue Wood Anemone, and the scarlet Windflower come out grandly in the glade. What more beautiful on grassy slopes than Primroses—not all yellow, but some of the coloured, even the truss forms in nearly all hues, and obtained by simply sowing the seed, while Cowslips and Oxlips are nowhere more at home. The hardier Lilliums need not be lost in the wilderness. Red-hot Pokers (*Tritomas*) shine amid its greenery, and once the autumn Anemones (*A. japonica* and var. *alba*) get established there are few flowers to excel them.

All the foregoing can be grown in grass that is mown two or three times a year, as the shave over such plants as Primroses is never so close by the scythe as to seriously damage them. The first mowing, however, must not take place until the Daffodils have died down, and on no account must the grass be cut over any plant whilst it has green leaves that would also be removed. In mowing, therefore, regard must be had to this, which is not at all difficult when the plants are in groups and stand out boldly. Any grass growing amongst herbaceous plants should be removed frequently with the hand for a time, then the naturalised plants will eventually overpower the grass instead of this overrunning them.

In the copse, a sort of thin wood, there are places for such plants as Pampas and other stately Grasses. The Willow Herb is more ornamental than Nettles, and the perennial Sunflowers will display the "survival of the fittest" by smothering coarse-growing weeds. Polygonums are equally assertive, possessing stately growth, handsome foliage, and large panicles of white flowers. *Pyrethrum uliginosum* takes care of itself, as also do the Michaelmas Daisies. What for colour can match the herbaceous Peonies and the Oriental Poppy? For bold characters in leafage *Rheum officinale* has few superiors. Variegated Comfrey tells well amid greenery, and Globe Flowers (*Trollius* species) out- rival Buttercups in grass. *Veratrum* grow tall, and have pyramidal spikes of white, black, and green flowers. The Golden Rods grow anywhere. *Hypericums* do well in partial shade, *H. calycinum* or

Rose of Sharon forming excellent cover, and having bright yellow flowers in summer and autumn.

Places may be found for Honeysuckles, rambling Roses, and the commoner Clematis, near unhealthy bushes or trees, and becoming mounds or cones of beauty. The Dog Rose loses none of its charms when Sweet Briar is near, and even shows with greater effect where *Rosa rugosa* is present, by contrast both in flower and leaf. As much cannot be said for the double-flowering Cherry associated with the wild Gean, but *Pyrus spectabilis* goes well with the blossom of the Crab, while the fruits of ornamental Crabs are charming. The Almond blends well with Blackthorn blossom, and the dark foliage of *Prunus Pissardi* makes a pleasing distinction between the green of the Sloe. Pink and scarlet Thorn blossom enhance that of the pearly white May. Hazel bushes show all the better for being in contrast with the purple-leaved variety. *Berberis dulcis*, *B. Darwini*, and *B. stenophylla* provide charming tints of contrasting yellow with the common Barberry. The White Beam tree adds to the beauty of the Bird Cherry. Weigelas associate well with Dogwood and Laburnums. Lilacs always impart beauty to the copse, and Mock Orange throws a delicious fragrance over all. White Broom enhances the effect of the yellow, and the Snowball renders Mountain Ash more lovely. The yellow, white, and red Ribes are more charming than the wild Gooseberry. *Leycesteria formosa* produces dark berries in the autumn, which hang in long bunches like Grapes, and is distinctly ornamental. For draping with a warm glow of colour shrubs of the copse order few plants equal *Tropæolum speciosum*, and to follow this the bright foliage and festoons of the Virginian Creepers on trunks of effete trees have a most pleasing effect.

Then there is the wood. It, too, may be improved by having in the open places great breadths of Winter Aconites, Snowdrops, Daffodils, and others of the flowers mentioned under the glade, with common Bracken introduced where there is none, also other Ferns in the shady parts, something different being added to the ubiquitous Bramble. Periwinkles will grow in the densest shade, so that there is no reason for not having cover. Even Ivy is much better than nothing, including groups here and there of the variegated forms for contrast and change. In most woods there are some not very thriving trees, and Ivy generally claims them. If these are in open places the Traveller's Joy will clamber over them, and give a pleasing change. I have in view a Spruce Fir, 50 feet height, overtopped by this climber, which in summer is a tower of beauty. Great woods of Firs, not one native except Scots, are extremely monotonous when they pervade valley, slope, and hill. British trees outlive and outshine in beauty and usefulness those introduced from other climes, yet we need them all, and have place for each, not to wholly displace, but to associate with and enhance the beauty of our native trees.—G. ABBEY.

SEAKALE CULTURE.

THE culture of Seakale, or rather the production of Seakale roots in quantity annually for forcing and for a late supply, is by no means a difficult task, and for the information of an inquiring correspondent I am pleased to give a short account of the simple method employed here. As far as I am aware there is nothing new in the cultural methods adopted, or that it differs from that employed in the majority of other gardens where Seakale is largely grown. For many years I have entirely discarded the use of pots and manure as a means of forcing, as this necessitated growing the roots on the same piece of ground for several years, and the unsightliness of heaps of manure could scarcely be permitted in the kitchen garden proper, and must of necessity be relegated to some out-of-the-way place. By planting annually a large stock is easily raised, from which a good supply of Kale may be maintained for at least six months—namely, from early in November to the May following.

The correspondent mentioned wishes to know (1) when the cuttings are taken, (2) when planted, (3) where blanched, if not in the open ground, (4) whether pots are used, or leaves only? I will, therefore, begin the season with the first lifting of fully developed crowns early in October, and finish with planting and other cultural details. As early forced Seakale is usually appreciated roots are lifted in the autumn as soon as the leaves will part from the crowns, which they usually do after a few degrees of frost; and as roots of all kinds start into growth the quicker after a perfect rest, they are forked out as cleanly as possible with all the rootlets attached, and allowed to lie on the surface for a few days, and should a frosty night or two occur so much the better. These roots are introduced to a dark, warm, enclosed end of the Mushroom house, and planted closely together in light soil. The early lifted crowns take the longest time to produce Kale fit for use, but the first or second week in November is about the usual time for

starting the supply, after which a regular succession must be maintained.

All the rootlets are cut away about half an inch from the base, and as the crowns are lifted all these are saved, placed in a heap, and covered with some half-decayed leaves, to preserve them in a fresh and plump condition. As the winter draws on, and danger of severe frosts become likely to impede lifting, a good portion of the crowns are taken up, the rootlets trimmed off and put away, the crowns laid in leaf mould, out of the reach of frost, or where they can be easily got up, and introduced to the Mushroom house at intervals of about five days.

PREPARATION OF THE SETS OR CUTTINGS.—During bad weather in December and January the rootlets that are to form the stock for planting the following season are selected and prepared. As the largest eventually make the strongest and best crowns, these are first chosen. Many are as large as a man's forefinger, a few larger, and none is used less in size than double the thickness of an ordinary cedar pencil. They are cut into sets or cuttings about 5 inches in length; the thicker end, where the crown will form, being cut straight across, the other or planting end with a sloping cut downwards. After preparing thus some are stood closely together in boxes of sandy soil, just level with the crown end, and others in similar soil or leaf mould in any out-of-the-way corner, and both left outside, but sheltered from frost until planting time arrives.

Before describing planting we will return to the crowns, about a quarter or rather less in my case, that remain to be dug. These are the crowns that produce the latest supply of Kale, and they are not lifted until just starting into growth, or about the middle of March usually. Some are simply planted closely together in a heap of leaf mould in some sheltered corner and covered with similar material to blanch, while the remainder, about two-thirds, are laid in in rows closely together in a cool north-east border, just covering the crowns with soil, over which, for blanching, is placed a bed of half-decayed leaves about a foot in thickness. This is the latest supply, and produced in this way Kale may be cut some weeks later than when blanched in the ground where it has been growing; but to keep it as late as possible I find it must not be lifted earlier than the time mentioned above. Some crowns treated in this way are still supplying very useful Kale, and will continue to do so for another week.

PLANTING THE SETS.—Assuming that a piece of ground in a well-exposed quarter of the garden has already been prepared by trenching and manuring, we will now return to the sets prepared for planting. Those in the boxes of sandy soil I generally plant a week or two earlier than the others, or about the end of March, if the soil is in a suitable condition. These by this time will have callused over and have produced numerous small crown growths, which if long enough should be reduced to one before planting. After the piece of ground has been trodden to break down lumps, and raked over to remove stones and rubbish, shallow drills are drawn out 15 inches apart.

When this is done a surface sprinkling of wood ashes and soot is given in the proportion of about six of the former to one of the latter, and the sets planted in these rows with a dibbler at 15 inches apart in the row. The crown of the set when planted should be just under the surface. When growth has started the ground is hoed, and the principal after culture required is to keep the quarter free from weeds, to look over the crowns, and remove surplus ones where more than one has started from each cutting. Another dressing of wood ashes and soot, with a little salt added, may be given before the foliage covers the ground much between the rows to assist a quick and strong growth, and if the summer be dry an occasional soaking of water applied will be of much assistance.—C. HERRIN, *Dropmore*.

[Our correspondent has sent us a sample of Seakale, than which no better could be desired. It is excellent.]

STRAWBERRY ROYAL SOVEREIGN.—It is only a short time ago since this Strawberry was first placed before the public. Even then competent judges were agreed that considering its splendid cropping properties, its handsome fruit, and its excellent flavour it would most assuredly come into great favour. This has proved to be the case, for it is now being grown in almost all gardens where Strawberries are largely cultivated, and it has more than fulfilled its early promise. By many growers it has been placed in the first rank, and amongst these may be mentioned Mr. Wythes of Syon House, by whom it is utilised as a second early variety for pot culture. This cultivator has a stock of 1000 plants this season, and their extraordinary productiveness has led to the decision that the number will be doubled for next year's supply. There are houses and shelves of Strawberries at Syon, the plants being in perfect health, and amongst the whole collection Royal Sovereign stands out conspicuously as a variety worthy of its name and fame.—D. R.

AVERY HILL.

TRAVELLERS on the North Kent line of the South-Eastern Railway will doubtless have often noticed on their left hand, between New Eltham and Sidcup stations, a handsome red brick mansion with a magnificent domed conservatory, and will have wondered, perhaps, to whom it belonged. It is the home of Mrs. North, and was built by the late Colonel North, being completed only just prior to his sudden death. Thousands of pounds were spent in the erection of the mansion, the palatial stables, and the perfect electric lighting plant; but with these we have nothing to do here, as our visit was to see the gardens, both out of doors and under glass. Like the residence, almost all is new, kitchen, flower, and fruit gardens, lawns having been formed, and new houses erected. But the whole of these are completely dwarfed by the winter garden, upon which the enormous sum of £60,000 is said to have been expended ere the erection was completed.

Before making specific reference to this, however, we may perhaps spend a pleasant half hour in the gardens outside. The name of the head gardener who acts as guide, will be familiar to every reader of the *Journal of Horticulture*. It is G. Abbey. It is not, however, the Mr. G. Abbey who writes in these pages, but that excellent gardener's son, who as a gardener is well worthy of his talented father. For upwards of eight years Mr. Abbey, jun., has been at Avery Hill, and during that time he has practically made the place. Immense forest trees have been felled, lawns and kitchen gardens have been formed, fruit trees planted, and the winter garden stocked. Not that it has taken eight years to do the work—not by any means, as that would have been far too slow for the late energetic Colonel, who wanted things done at once, done well, and done quickly. The natural outcome of this desire was that almost unlimited labour had to be employed, and the strain of planning and supervising that fell upon the gardener must have been very great indeed. However, he is prone to take things calmly, and so came forth from the ordeal with flying colours.

Of what may be termed formal flower gardening there is really none, for the beds are distributed at unequal intervals and are planted in various styles. At the time this visit was paid the Dutch Tulips were making a really gorgeous display both in beds and in borders in various parts of the grounds. The bulbs had not been planted in distinct colours according to variety, but in mixture, though only good sorts had been utilised. In a sheltered corner Auriculas were flowering with the greatest freedom. Amongst them are some of great promise that have been raised by the gardener.

A glimpse is caught in passing of a superb bed of Primroses in a secluded nook, where they had been planted to afford an abundant supply of flowers for Primrose Day. Tulips and Narcissi are also seen, and a new Pansy that has been raised at Avery Hill, and which is named Colonel North. It is entirely distinct from all varieties in commerce, and is at the same time of very great beauty. The prevailing colour is rich velvety brown, the lower portion of the flower being a glossy black-brown. The whole is edged with gold in a very narrow line. It is a distinct light edged Picotee, and is useful for borders or beds, in which it flowers over a very extended period, as well as for pot culture. It is a telling acquisition, of which more ought to be heard in the future. Then there are large numbers of herbaceous plants here and there, besides a small pond surrounded by a little rock garden, that has been formed for aquatics, of which a fine selection has been planted. Suitable plants have been disposed round the pond, and the whole will, under favourable conditions, develop into one of the most interesting features of the estate when the plants have become thoroughly established and at home.

Wall fruit is by no means a great feature, for the simple reason that there is an exceptional dearth of wall space, though where there is some it is occupied by the healthiest of Peaches and Nectarines that one could reasonably wish to see. Pears and Apples in bush form in the garden are magnificent examples of the best management, though on the former fruit will be none too abundant this season, because the frost has destroyed the essential organs in thousands of beautiful blossoms. The trees are not as a rule large, it is not desired that they should be, but they are models of pruning, while there is no vestige of insect pests. Root as well as branch pruning is constantly resorted to, and the results achieved fully justify the grower in the system he adopts. Small fruits of all kinds receive equally as good attention, and give the same handsome return for the labour bestowed upon them.

The dimensions of the vegetable garden are very limited, and for the maintenance of a proper supply the greatest care and attention have to be bestowed so as to insure the utmost being secured from the ground that is at disposal. To effect this, not only are kinds and varieties selected with the utmost discretion, but the working of the ground is most efficiently carried out, and of course no weeds are tolerated, as all the food in the soil is required for the profitable and legitimate crops. Fortunately plenty of manure can be had from the stables, and this being of good quality materially assists in securing the necessarily heavy crops. The actual area of this department is 2 acres, but a fair portion of the margins to the walks of this is occupied by a considerable number of the fruits mentioned in the preceding paragraph.

The under glass plant department is neither very extensive nor very convenient, but here again the utmost advantage is taken of every foot of available space. To give a list of all the plants grown would be a wearying task to reader and writer alike, for the collections are mainly the same in all well furnished establishments. The difference lies in the condition of the stock. In some places it is good, in others indifferent, and occasionally bad, according to the amount of time and the intelligence that are accorded to them. At Avery Hill the two predominating characteristics are health and cleanliness, simply because the requirements of the plants are studied and steps are promptly taken in case of insect invasions. Foliage plants for indoor decoration are extensively grown, as is proved by the many handsome little *Dracænas*, *Crotons*, and Palms that are to be seen. In one large span-roofed structure there were several *Azaleas* that made a brightly pleasing show.

The way the frames are pressed into service in these gardens shows to what useful purposes they may be put, and how valuable they are to the gardener who has large supplies of plants and other things to maintain. Here, again, it is not proposed to enumerate the many plants therein, but specific reference to the *Chrysanthemums* may be made with every justification. There are many hundreds of plants both grown for exhibition and for cut flowers, and all alike are in splendid condition. It would be hazardous to venture to predict as to what form they will eventually attain, but it is certain that unless something unforeseen and uncontrollable occur they will produce flowers well worth a journey to see, especially as the collection comprises many of the best varieties in cultivation.

We will now pass within doors again, this time to see Vines, Figs, and Peaches. Of the former there are several houses, containing all the standard varieties, which are alike in one respect only, and that is their general excellence. Early as it is for the Vines at Avery Hill, one can readily see how easily the grower is master of the cultural details that are entailed with them. There is nothing but clean straight rods, healthy foliage, beautiful laterals, and the promise of bunches in abundance. The houses smell sweet and fresh, as vineries should do, and the borders have been properly made. One looks in vain for insect or fungus, for Mr. Abbey is, like his father, "down" on anything that may prove detrimental to any of the plant life under his charge. As there is no orthodox trellised Peach house there are no trained trees under glass. There are trees all the same that are almost monsters growing in one of the loftiest houses, and the gardener is so pleased with the manner in which these bear, the excellence of the flavour of the developed fruit, and the handsome appearance they take on when ripe, that he is perfectly in love with them, and absolutely resigned to the absence of trained specimens.

Let us turn into the winter garden, which is a structure of singular magnificence, either when regarded from the interior or the exterior. No matter at which door one may enter, there rise before huge Palms, stately Bananas, whose leaves hang over the whole as a canopy of green. Look at the photographic reproduction that is given in fig. 82, and from it get some slight idea as to the plants that are there growing. The centrepiece that may be seen before you, and round which the paths diverge on each side, is of rockwork, built to represent the base of a giant tree that has been hollowed out. It is planted with *Musa ensata* and *M. Martensi*, rising to a height of about 25 feet, and crowned, as it were, by a central specimen of *Cocos flexuosa*, which, towering up in all the majesty of its 50 feet, droops gracefully over.

The groundwork of this pseudo monarch of the wood is *Selaginella* dotted with *Begonias*, and having hanging over the sides *Tradescantia zebrina* and *Cissus discolor*, with Ferns peeping from the crannies in the bark. On each side of the path are *Musa paradisiaca*, and the bulk of the Palm leaves that are visible in the picture are those of *Phoenix canariensis*. Up every pillar travel either *Passiflora princeps* or *Cissus discolor*, and at each corner of the beds is an immense *Clivia*, with its handsome leaves and orange-coloured flowers. Everything in here is spotlessly clean.

No less beautiful is the rock fernery, and the internal arrangement is even more artistic than is the case in the winter garden. Here Mr. Abbey showed his genius in designing, for he conducted the whole of the work, which entailed the use of upwards of 700 tons of rock and cement, which was put in place, and the plants inserted, in the short space of six months. Quick work, indeed, and admirably executed. The structure, of which the photo (fig. 84, page 413) shows about one-third,

FIG. 82.—BANANAS IN THE WINTER GARDEN.

is 80 feet long, 40 feet wide, and 50 feet high, and the planning of the rockwork has been done so that no walls are touched, one may consequently walk all round and examine almost every individual plant. The centre is a small lake, boasting a miniature island, and in the water there are *Nymphæas Laydekeri rosea*, *odorata*, and others, with *Nelumbium speciosum*. At the head of the lake, looking from the ball-room steps, are four small cascades, which make a charming picture, but do not appear in the illustration. Tree Ferns are represented, while about sixty choice species of other Ferns are luxuriating here and there, other plants being added for diversity and effect. Health, grace, and strength are conspicuous features here.

We have not mentioned all the plants and things worthy of mention on this estate, for there are the Conifers and the orchards; but we must draw to a close. We would, however, acknowledge our indebtedness to Mr. Abbey for providing the photographs, and also for his guidance and kindness on the occasion of the visit to Avery Hill.—H. J. WRIGHT.

IN SEARCH OF SUNSHINE.

THE CITY OF THE FLOWERY PLAIN.

A DULL sky, a sea of slush—London. A golden stream of sunny light, a broad expanse of brilliant blossoms—Haarlem. A few hours, made comfortable almost to luxuriousness by the enterprising Great Eastern, brought about the wonderful transformation. One evening I gazed upon a melancholy vista of dripping roofs, draggly trees, and sloppy streets, the next morning my eyes were gladdened by visions of beauty almost too great for words. I struck sunshine at the first attempt, and not sunshine alone, but its best accompaniments, hosts of gay and fragrant flowers, spreading for miles in every direction, lining the roadsides, filling the fields, showing themselves in every window, decorating the children on their way to school, heaped up in deep baskets and high mounds, dominating, in fact, the whole face of animate and inanimate nature. The cost of seeing it all is about the price of a day at Sandown or Epsom, when every winner has mysteriously turned out to be a loser, just in the sweet old way. Happy gardener! whose "tip" is to pin his faith on the cycle of floral pleasure, which always catches the judge's eye.

Since first I rambled by the dykes and dunes of Holland there have come about certain changes in the route, all making for speed, comfort, and economy. Time was when the traveller had to feast his eyes on banks of unspeakable mud two or three hours after the sea journey proper was over, then work his way across a busy town to the station. He can do that still if it so please him, but the necessity for it has been removed by the provision of a spacious landing quay, custom house, and station at the mouth of the river. By an inspiration of terse and expressive nomenclature this has been called the Hook of Holland. It really provides links for a chain engirdling all Europe. It connects directly with Hamburg, Berlin, Cologne, and Bale. The trains are swift; the steamers are magnificent combinations of seaworthiness and comfort. Convenient through tickets are issued at special rates. As an Englishman I have three wishes—to go somewhere, to get there quickly, and to escape extortions on the way. It is my own fault, and not that of the railway company, if I am not satisfied with the confidence reposed in the Great Eastern.

The untravelled Briton has a certain suspicion of foreigners. Well, the stranger who takes you to his bosom with the greatest fervour is usually the likeliest to have his hand in your pocket. But, speaking broadly, I think a man who can cope successfully with a London cabman will prove equal to any continental emergency. Occasionally there is a preliminary stumble at the Custom House. For instance, it is one of the eccentricities of the otherwise admirable Dutch Government that it regards tobacco as a necessity and admits it untaxed, while it holds sugar to be a luxury, and pops on a stiff duty. A friend was pulled up sharply for possession of a sweet cake. The Customs official blandly smiled and asked for 4s. The staggered owner hesitated and tried bluster; no use. Then he resorted to strategy. He magnanimously presented the cake to the officer and passed on. But the latter, more bland than ever, sailed in again. He took the duty and the cake as well! If when travelling you want to have your future career tenderly blessed give porters and tram conductors abroad 3d. If you want your ancestors and your descendants for several generations to share in the blessings heaped upon you give a ½d. instead of 3d., but first of all allow yourself to be cheated out of a 1d. Such are the teachings of experience.

The way to reach the heart of the bulb district is to take the train to Leyden *via* The Hague (change here and wait twenty minutes or half an hour, same platform). A steam tram runs about every hour from Leyden to Haarlem, and passes through all the bulb villages, such as Sassenheim, Lisse, Hillegom, and Bennebroek. I do not speak Dutch, and the worthies who drive and conduct the trams did not speak English. We were, however, on terms of the warmest mutual regard and respect, and I went up and down, around and about, with the greatest confidence and without the slightest confusion or mistake. The secret is a judicious distribution of largesse. A tram conductor who received 5 cents (one penny) every time he put me down at exactly the right spot never fell into forgetfulness. His eye was upon me all the way. Frequently he smiled encouragingly, and when the right moment came he was there at the door, cheerfully beckoning and bowing. If I had not got out then he would have carried me and expected no more.

My route, for personal reasons, was not the one indicated; but had it been, probably my first stop would have been Hillegom. Within two minutes of the tram terminus there is the nursery of

Messrs. Van Meerbeek & Co., who do a large retail trade in England. The place is well worth a call, and the managing partner, Mr. Adrian van Waveren, is a courteous and willing guide. The business has enormously increased since I visited the nursery, seven years ago. There are larger stores, more land, and new houses. Descriptive catalogues are published in four languages—English, French, German, and Dutch; but the principal part of the trade is with England. It is obviously done on complete and careful lines, for the stocks are very large and clean. I was very nearly too late for Hyacinths and Narcissi, and a little too early for Tulips; but I fared best with the latter. It would be tedious to run into lists of names, but I might mention a few special things. Although the day of the Dutch florists' Tulip is in the past, there is a constant and increasing demand for new varieties of the early section—so beautiful for beds, and indeed also for pots. On a large farm these novelties are seen in quantity. For instance, there is the true Scarlet Pottebakker, a variety which we highly esteem, but do not always receive. It is known in Holland as Grace Darling, whereas the spurious Scarlet Pottebakker is grown under the name of Verboom. The latter may be a good Dutch name, but Grace Darling is a glorious English one, and I can vouch for it that the variety is far superior to the other. So rich is it, so brilliant, so glowing, that the sight of it is almost as cheering as the sight of the devoted English fisher girl must have been to the forlorn mariners in whose salvation she immortalised herself.

Rose Hawk, a beautiful form of the well known White Hawk, is equally as good as that fine variety. Amongst later bloomers Koh-i-Noor, Marquis de Westrade, and Pink Beauty must be mentioned. The first is a very dark red, the second a yellow with red stripe, and the third a very delicate pink, distinct in shape. All are worth growing by Tulip lovers. There are several notable doubles. Queen Emma is a bright red with lighter shadings, La Coquette is a deep yellow with orange shading, Mrs. Cleveland is a fine rose, Prince of Wales is a rich dark red, Vuurbaak a fine glowing scarlet. About the best new yellow is Golden King. The variegated-leaved Tulips are not very extensively grown in Britain, but they would be if they could be bedded as they are in Holland, for they are exceedingly beautiful. Many are forms of well known green-leaved sorts; for instance, there are variegated Duc Van Thol, Cottage Maid, Yellow Pottebakker, Royal Standard, La Candeur (d), Rex Rubrorum (d), and many other well known Tulips.

Messrs. Van Meerbeek have added greatly to their glass. They grow enormous quantities of Gesneraceous plants. Achimenes and Tydas are a special feature. One of the finest plants in flower at the time of my visit was *Ismene calathina*. Most people would consider it hardly so graceful as *Pancratium fragrans*, but it bears a general likeness to that favourite plant, and when its early flowering character and adaptability to forcing are borne in mind its usefulness becomes apparent.

From Hillegom, with its handsome villas and generally prosperous air, to the next place, the village of Bennebroek, there is nothing but bulbs. Only a trade buyer would wish to spend day after day in closely scrutinising the individual stocks of every grower; but the most casual amateur would find food for admiration in the magnificent spectacle of hundreds of acres of Hyacinths and Tulips. I do not wish to rhapsodise, for if I did I might be led on to the same lengths as the writer who peopled the waterways with Naiads. Fancy Naiads in a Dutch canal! Barges laden with cow manure if you like, for there are long strings of them, but Naiads! I pass on. However, the general view is so magnificent that plain words seem inexpressive after all. The flat fields are alive with colour. Some people call Tulips gaudy, but when scores of varieties blend their hues with each other there is no garishness. There is really hardly any limit to the diversity of shades, and each variety has its character. The most effective soon proclaim themselves. Vermilion Brilliant, the true Scarlet Pottebakker (Grace Darling), and Rembrandt are three of the finest reds. Chrysolora, Ophir d'Or, and Yellow Pottebakker have a tussle amongst the yellows, and Joost Van Vondel (white) and White Pottebakker are very prominent amongst the whites. But some of the most beautiful sorts do not fall into any of the above classes. Proserpine stands in one of its own, so do Le Matelas (a beautiful rose), Joost Van Vondel (crimson and white), the old familiar Keizer's Kroon; Cottage Maid, most beautiful of rosy pink sorts; Queen of the Netherlands, soft flesh colour; Thomas Moore, almost orange coloured; Van der Neer, purplish lilac; Wouwerman, claret.

It is the same with Hyacinths. The growers evolve many new sorts yearly, but they have not yet improved on King of the

Blues. It is unique in habit and beautiful in colour. One of the disappointments of a bulb tour is the reflection that only if one were wealthy could he hope to emulate these superb beds. Even then it would want culture of the best. Thousands of spikes are seen in the open fields such as we rarely produce even in pots. The same with regard to other varieties—Queen of the Blues for instance, which is a lovely pale blue, Grand Maître, Czar Peter, and Lord Derby. Then amongst the reds there are Von Schiller, the comparatively cheap Gertrude, Robert Steiger, Roi des Belges, Vuurbaak, Norma, Cardinal Wiseman (a grand sort), and Gigantea. First always amongst the Whites is La Grandesse, but Paix de l'Europe, Belle Blanchisseuse, Blanchard, and Madame Van der Hoop also show up extremely well. Every one of these sorts is represented by some magnificent beds, and it is at once a source of envy and delight to observe the splendid trusses which spring from a bed of sand dressed with cow manure in the open air.

There is, as might be expected, a strong family likeness between the bulb farms. The owners, of course, see differences enough, just as Mormon mothers are able to single out the babies in a family of thirty or forty. But to a foreign visitor it is impossible to distinguish. The confusion is helped by the singular fashion in which the farms are mixed up. One field belongs to A, the next to B, the third to A again, and so on. I tried to grasp the limits of the possessions of the Van Waveren family, some of the members of which gave me very kind help and guidance, but I am not quite sure whether I succeeded. This is somewhat the order of events—I admired a bed of Keizer's Kroon Tulips. "Ah! Messrs. F and H, what a beautiful bed, and what a charming lot of Cottage Maid you have on the other side of the ditch." Messrs. F and H exhibit mixed feelings. "The Keizer's Kroon," say they, "are ours, but the Cottage Maid belong to Messrs. J and A." I look again, and proceed with diminished confidence. "Well, you have a good bed of La Grandesse there, and the Blanchards next to them are splendid." Messrs. F and H smile dubiously once more. "Ye-es! but the Blanchards belong to Messrs. H. H. Van Waveren." I made a further attempt, but after finding that there were still four more firms, varying slightly only in the initials, I gave it up. I am assured, however, that despite the extent to which the plots are mixed the growers never make the mistake of manuring each other's land, or of praising each other's stocks.—W. PEA.

APPLE EASTER ORANGE.

It is so seldom that a dessert Apple is honoured with an award of merit by the Royal Horticultural Society so late as the 27th of April that we give a figure of the above variety, which was sent by Mr. Hillier on the date mentioned, and met with the Committee's approval. The fruit is briefly described in our issue of April 29th, page 361, and it need only be said now that the Apples exhibited bore a general resemblance to large fruits of Cox's Orange Pippin, but were darker and more boldly streaked, also quite different in quality. The variety is totally distinct from Cox's famous Apple, and we do not know whether Mr. Hillier was the raiser of the much later Easter Orange or not.

TOMATOES IN POTS.

THE present is a suitable time to carry out the final potting of Tomatoes intended to furnish the main crop. The plants are easily managed in pots and produce good crops, provided certain essentials are secured for them. These essentials are in the case of pots 11 or 12-inch size, so that there is abundant room for the roots which should eventually occupy them entirely. The drainage ought to be effective, but not too abundant. Water is required so frequently when the plants are in active growth that it is imperative for the surplus water to pass freely away; yet when the drainage is too free the escape is more rapid than desirable.

The soil is the next item of importance. The main thing to guard against is not to employ a light or freely manured compost. A soil rich in organic matter will induce growth which does not tend to be fruitful. This must be guarded against, in order that an early fruiting condition is secured; the plants can then appropriate rich food to advantage, given to them as they demand it. The best soil is undoubtedly substantial turfy loam. Should the material be rather poor in character add a sixth of decomposed manure. Leaf soil must not be used freely, if at all. To insure porosity broken charcoal and a small quantity of pounded brick may be intermixed.

The crocks forming the drainage should be carefully covered with a thin layer of turf or the rougher parts of compost. On this place the plants, one in the centre of each pot. Healthy,

sturdy plants that have just filled their pots with roots are the best. Those occupying 4½ or 5-inch pots are better than larger or smaller plants. If turned out of larger pots there is necessarily a greater bulk of roots and soil, which when properly covered in the fruiting pots require a large bulk of compost. This occupies considerable space, because it is highly desirable that a portion of stem should be buried from which new roots will be emitted. The compost must be placed in firmly, using a blunt stick so as to compress it sufficiently firm. A short-jointed growth is promoted thereby, as the roots are induced to become fibrous.

After potting place the plants close to the glass on a light sunny shelf. Withhold water for a day or two according to the weather and the temperature, then give sufficient to moisten the whole mass. Successive waterings must be carefully given, so that the compost is not unduly saturated before the roots have had time to enter it. If water is given only when the soil over and around the old ball dries, the requirements of the plants will be met, and their steady, healthy progress insured. The attention given to Tomatoes at this stage should be regular, as it ought to be at other periods; but from the time of the final potting or planting until fruit sets is important. Too free applications of water will cause sappy growth and prevent the formation of flower trusses, and

FIG. 83 —APPLE EASTER ORANGE.

therefore fruit. Abundance of light, and a proper temperature, with a regular circulation of air, must not be omitted.

When the first bunch of fruit has set the critical period is passed. The pots may then be placed in a permanent position, the plants staked or arranged for training on wires, but light and plenty of sunshine must have free access. Tomatoes cannot and will not endure shade.

As soon as the soil in the pots becomes freely occupied with roots, and a number begin to appear on the surface, a top-dressing of compost can be given. This may be of a richer character than that used in potting. Continue these applications each time fresh roots appear. They stimulate root action, and the setting of the fruit is practically certain when this is encouraged to be actively continuous.

A dry and airy atmosphere, with a little warmth at night, is undoubtedly of great assistance to Tomatoes during the early summer. When fire heat has been employed and is suddenly discontinued fungoid diseases may be induced, but in a comparatively dry warm temperature they cannot obtain a footing. In a suitable structure, and with careful, regular, intelligent management, it is possible, in my opinion, to avert attacks from fungoid diseases.

The method of training the plants ought to be referred to. For pot culture the single stem system is best. Let the plants extend without topping the leader at any point, but rub out as soon as formed the small side shoots which appear in the axils of the principal leaves. This is all the pruning or training required, except tying the stems to stakes or wires as they advance. Shortening the main leaves to the extent that some cultivators do is wrong practice, and is only justifiable when the fruit is approaching the ripening period.—E. D. S.

WEATHER IN LONDON.—The winds during the past few days have been very keen and gusty, sometimes accompanied by cold rains, but more often dry. On Thursday last it was cold and very showery; but on Friday it was much brighter, though there were two or three slight showers in the afternoon and evening. On both Saturday and Sunday gleams of warm sunshine shone out between periods of dullness. The wind on each day was a little boisterous and cold. Towards the evening of Monday heavy showers fell, but Tuesday was clear and lovely until night, when rain again fell. Wednesday was clear and cold.

WEATHER IN THE NORTH.—The ungenial weather of the preceding fortnight has continued throughout the past week. Almost every night the thermometer has been at or under the freezing point, and piercing northerly winds have prevailed. The evening of Friday, when gentle rain fell for some hours, and Saturday morning were somewhat milder, but the afternoon of the latter day, Sunday, and Monday, were bitterly cold, and there was no improvement on Tuesday morning.—B. D., *S. Perthshire*.

DEATH OF MR. R. OWEN.—It is with deep regret that we have to announce the sudden death of Mr. R. Owen, Maidenhead, which took place last Saturday afternoon. Few men were better known in the Chrysanthemum world than Mr. Owen, who was formerly gardener to G. Schwabe, Esq., and went into business on his own account about thirteen years ago. Mr. Owen's death was brought about by heart disease at the age of fifty-seven, and we tender our sympathy to his relatives and friends.

PLOUGHING IN A GREENHOUSE.—At Redlees, Isleworth, a curious and novel sight has been witnessed, a local paper says, this spring. The owner has erected ten huge glass houses, 600 feet long by 40 feet wide, and, after calculating the cost of digging, decided to dispense with manual labour in favour of the plough. Two ploughs have been at work under the glass, ploughing from end to end, the ground being afterwards harrowed in the ordinary way. Although the men and horses are under cover, they have to wait for favourable weather, such work being impossible in bright sunshine owing to the excessive heat. The houses are intended for the culture of Tomatoes.

NATIONAL CO-OPERATIVE SHOW.—The new schedule of this annual Show has just been issued. The prizes are increased to £350 in cash, besides gold, silver, and bronze medals, framed certificates, and other awards. The Agricultural and Horticultural Association contributes £200 to the prize list, and the Crystal Palace Company £150. The Show is fixed to be held on Friday the 20th and Saturday the 21st of August at the Crystal Palace, concurrently with the Great National Co-operative Festival. Mr. George Waugh again acts as Hon. Director of the Show, and Mr. Edward Owen Greening as Hon. Secretary. The schedule may be obtained on application to the Hon. Sec., at 3, Agar Street, Charing Cross, W.C.

WOLVERHAMPTON GARDENERS' HORTICULTURAL CLUB.—At the monthly spring meeting of this Society there was a goodly attendance of members to hear an essay on "British Ferns and their Allies," by Mr. W. Gardiner, Harborne, Birmingham. The essayist's object in reading a paper on this subject was based on a twofold purpose—viz., from a desire to incite an increased love for, and an extension in the cultivation of this highly interesting and most useful class of our native flora, and with this object in view he sought to inculcate it by references more in relation to the various and beautiful attributes possessed by Ferns; also of their unique and wonderful reproductive organisation, including likewise, as the various genera were passed in review, references to the nomenclature and etymology of the same as far as practicable, than to cultural details. The essay was illustrated with a small collection of dried fronds. Altogether the subject proved of an interesting character, and was followed by an instructive discussion, in which Messrs. Simpson (the Chairman), Lowe, Bishop, Bradley, and Banner took part, elucidating also the fact that Mr. Bradley has charge of a very good collection of hardy Ferns, and in which such as the Parsley Fern (*Allosorus crispus*), and the comparatively rare Scaly Spleenwort (*Ceterach officinarum*), which latter is somewhat difficult to cultivate, flourish satisfactorily.

GARDENING APPOINTMENTS.—Mr. John H. Cumming, for the past ten years gardener and steward to Viscount Gough, St. Helens, Booterstown, Dublin, has been appointed gardener and steward to the Lady Stewart, Glandtully Castle, Ballinluig, Perthshire, taking up the duties there on May 28th. Mr. David Sime, gardener to Colonel Clements, Killadoon, Celbridge, Co. Kildare, has been appointed gardener and steward to Viscount Gough, St. Helens, Booterstown, Dublin. Mr. David Kirk, foreman in the gardens at Willow Park, Booterstown, has been appointed gardener to Colonel Clements, Killadoon, Celbridge, Co. Kildare.

EARLY TOMATOES IN THE ISLE OF WIGHT.—In reply to G. R. Peerless (page 363) *re* particulars of above, I may say that the plants mentioned were raised from seeds sown in December, the exact state of sowing not being recorded. The plants were grown freely in a minimum temperature of 55° to 60°, and in their early stages received the syringe, as well as a free circulation of air. They were potted into 10-inch pots, in which they are fruiting, early in February, the soil containing no manure, and now the plants are 8 feet high, single stem, with healthy foliage hanging over the pot tops. Some of the leaves measure 20 inches long and 16 inches wide. There is an average truss of fruit (with from six to eight fruits) for every foot of growth. Mr. Barkham attributes his success to a judicious amount of heat, air, and moisture in suitable proportions. The faddy idea that Tomatoes should never be syringed he considers moonshine, and one's common sense should be a great guide in the cultivation of all plants. The variety above mentioned is a cross between Early Ruby and Frogmore Selected.—S. H.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Lord Rothschild, who is to preside at the annual dinner of this admirable Association, which will be held at the Hotel Metropole on Wednesday, the 26th May, makes the following appeal. "I have consented to preside at the fifth-eighth festival dinner in aid of the funds of the Gardeners' Royal Benevolent Institution, and I venture to ask for the kind assistance and support of all lovers of flowers and gardening. The charity—the only one of its kind in the United Kingdom—whose cause I have undertaken to plead, has been established fifty-nine years. It has distributed £71,000 to worn-out gardeners, horticulturists, and their widows in distressed circumstances, and has now upon its funds 161 persons—men and women—who are receiving permanent relief at an annual cost of nearly £3000. To meet this expenditure the only assured income is £900, leaving the remainder to be made up by subscriptions and donations. Towards this object I earnestly solicit generous aid. I may mention that the Queen has been the patroness of the charity for forty-five years, and that in order to commemorate the sixtieth year of Her Majesty's glorious reign, a special fund, to be called the 'Victorian Era Fund,' is being raised for the benefit of applicants who are awaiting aid, and who cannot at once be assisted for lack of means."

MAKING MORE GARDENERS.—The following regulations for junior scholarships in practical gardening are issued by the Technical Education Board of the London County Council:—"The Board has decided to institute junior scholarships in practical gardening tenable at the gardens of the Royal Botanic Society in Regent's Park. These scholarships are intended to offer to boys who wish to become gardeners an opportunity of going through a thorough course of training. The following are the regulations relating to the award of the scholarships:—1, The Technical Education Board will proceed in July to award three junior scholarships in practical gardening tenable at the gardens of the Royal Botanic Society in Regent's Park. 2, The scholarships will be awarded, not upon the results of a set examination, but upon a consideration of the record and qualifications of the candidates. Each candidate must furnish the Board with a statement as to his past career and his future intentions, and his application must be supported by specific recommendations from his head master and other teachers. 3, The scholarships are open to boys who are not less than fourteen, and not more than sixteen years of age on May 1st, 1897. 4, Candidates must be resident within the Administrative County of London at the time of the award of the scholarships, and must continue to reside within the county during the tenure of their scholarships. 5, The scholarships will provide free instruction in horticulture at the gardens of the Royal Botanic Society in Regent's Park. They will also provide a maintenance grant of £20 per annum to scholars under fifteen, and £25 per annum to scholars over fifteen years of age. The scholarships will be awarded in the first instance for one year, but will be renewable for a second, or even for a third year, if the progress of the scholar is satisfactory to the Board. 6, No candidate will be eligible for these scholarships whose parents are in receipt of more than £250 per annum."

— APRIL WEATHER AT HODSOCK PRIORY, WORKSOP.—Mean temperature, 44.5°. Maximum in the screen, 67.6° on the 29th; minimum in the screen, 25.3° on the 5th. Minimum on the grass, 14.6° on the 5th. Number of frosts, in the shade nine; on the grass nineteen. Sunshine 136 hours, or 33 per cent. of the possible duration. Rainfall, 1.31 inch. Rain fell on seventeen days. Rather showery, with some sharp frosts at the commencement. Mean temperature the same as in March, and the nights colder. Vegetation late.—J. MALLENDER.

— THE WEATHER LAST MONTH.—April was changeable, but severe frosts only occurred on two mornings. The prevailing direction of the wind was N. on fifteen days. Total rainfall, 1.52 inch, which fell on sixteen days, this being 0.28 inch below the average for the month. The greatest daily fall was 0.32 inch on the 6th. Barometer (corrected and reduced), highest reading 30.285 inches at 9 P.M. on the 10th, lowest 29.122 inches at 9 A.M. on the 1st. Thermometers, highest in the shade, 66° on the 29th; lowest, 25° on the 11th. Mean daily maxima, 51.46°. Mean daily minima, 37.06°. Mean temperature of the month, 44.26°. Lowest on the grass, 16° on the 11th; highest in the sun, 127° on the 15th. Mean of the earth at 3 feet, 44.10°. Total sunshine, 146 hours 40 minutes. We had four sunless days.—W. H. DIVERS, *Belvoir, Castle Gardens, Grantham.*

— ROYAL METEOROLOGICAL SOCIETY.—The Council has occasionally been urged to hold the meetings of the Society in the afternoon instead of in the evening, and is desirous of consulting the convenience of the Fellows in this matter. It has therefore thought that as the next two meetings cannot be held at the Institution of Civil Engineers afternoon meetings might be tried on these occasions. The meeting on May 19th will be held in the rooms of the Royal Astronomical Society, in the quadrangle of Burlington House, Piccadilly, W., at 4.30 P.M., when the following papers will be read:—"The Rainfall of Dominica, West Indies," by C. V. Bellamy, F.R.Met.Soc., Associate M.Inst.C.E.; "On the Mean Monthly Temperatures of the British Isles, 1871-95," by R. H. Scott, F.R.S., and F. Gaster, F.R.Met.Soc.

— RICHMOND HORTICULTURAL SOCIETY.—Ninety-eight classes are enumerated in the schedule of this Society, whose show will be held in the Old Deer Park on Wednesday, June 23rd. As usual there are open and restricted classes, together with Society's and special prizes. For a group of plants £14 is offered in four prizes, while to competitors who show in this class and do not gain a prize a premium of £1 will be given. Six stove and greenhouse plants take £5, £4, and £3 as the respective prizes. For Roses, twenty-four trebles, £6 is scheduled; other prizes for plants, cut flowers, fruits, and vegetables being equally good. Schedules may be obtained from the Hon. Secretary, Mr. A. A. Chancellor, Old Palace Place, Richmond.

— ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION.—It is very pleasing to record a steadily increasing interest in the work of the above Association; new members are being continually enrolled, and there are very few of the principal gardeners in the island now who have not joined the ranks, and it cannot fail to do good work in the advancement of horticulture generally in this favoured spot. It is fortunate in having a very popular President in Dr. J. Groves, B.A., F.G.S., who throws a deal of energy into the work, and a capital Hon. Secretary in Mr. S. Heaton, F.R.H.S., who seems to have the knack of drawing gardeners together, not always an easy task. On Saturday last, May 8th, the President, the Hon. Secretary, and about fifty other members responded to the invitation of the Rev. H. Ewbank, F.R.H.S., to visit his garden at St. John's, Ryde. The weather was delightfully fine, and the members found therein much to interest them, the garden being noted for the very choice collection of rare alpine and other plants of quaint or botanical curiosities. Many of the Irises were over, but *I. iberica* was at its best, and other varieties coming on. A fine clump of *Paeonia tenuifolia*, with crimson flowers and finely cut foliage, was conspicuous among other choice and interesting plants. Tea was provided on the lawn and heartily enjoyed, Mrs. Ewbank and others being assiduous in assisting and attending to the wants of the members. After the tea the President proposed a hearty vote of thanks to the Rev. and Mrs. Ewbank for their kind invite and hospitality, which was seconded by Mr. C. Orchard, and heartily responded to. The members afterwards availed themselves of the opportunity to look over the adjacent grounds of Appley Towers by the kind permission of George Hutt, Esq., when they had the opportunity of seeing some fine specimens of flowering shrubs in full beauty, one plant of *Choisya ternata*, measuring at least 12 feet through, being a perfect picture. In the evening the President read a paper at the Town Hall, Ryde, on "The

Influence of Microbic Life in the Nutrition of Plants," which was well attended and listened to with much interest. A good collection of Orchids was exhibited, and Mr. J. Barkham, Longford, was awarded a first-class certificate for a dozen fine fruits of Cucumber Longford Hall. The Orchids exhibited were awarded a cultural certificate.—C. ORCHARD.

— ROBINSON v. WARD, LOCK, & CO. (LTD.).—The plaintiff in the above action, on the 2nd day of April, obtained from His Lordship, Mr. Justice Kekewich, in the Chief Division of the High Court of Justice, an order perpetually restraining the defendants from printing, publishing, selling, or disposing of, and from advertising, offering, or exposing for sale any newspaper, periodical, or publication by the name of "Gardening Illustrated," or by any other name so similar to "Gardening Illustrated" as to induce the public to believe that such newspaper, periodical, or publication is the paper published by the plaintiff.

— THE CRICKET SEASON.—In a few days the cricket season will be in full swing, and matches will be played from one end of the country to the other. The employes of Messrs. Sutton & Sons, Reading, are, like their employers, up to date, for they have sent us the match card of Suttons' Cricket Club, with the fixtures on it for the current season. There are three teams—namely, A, B, and junior—and amongst them they will play, circumstances permitting, forty matches at home and away. The opening game will be on May 19th, and the closing one on August 28th. We wish the willow wielders and the leather trundlers every success.

— FINE MUSHROOMS.—I herewith send you a small box of Mushrooms for your breakfast, if you will kindly accept them. They are grown from instructions in "Mushrooms for the Million." If you think they are worth it, you can acknowledge them in your next issue of the Journal. I have splendid crops, plenty of specimens weighing over $\frac{1}{2}$ lb., some over 1 lb. each, quite as fresh as those sent.—W. F. SMITH, *The Church Close Nursery, Clent, Stourbridge.* [The specimens are accepted with thanks. They are certainly worthy of public acknowledgment, as finer and fresher examples we have not seen, and scarcely expect to see this year. Mr. Smith is to be congratulated on his successful cultivation of the delicious esculent.]

— "AMATEUR WORLD OF HORTICULTURE."—Such is the title of a book of twenty-six pages that is published by the National Amateur Gardeners' Association for gratuitous distribution amongst its members, also those of the National Cactus and National Viola Societies. Besides a few editorial notes papers are given on Cactuses by Mr. Lewis Castle, and on Violas by Mr. W. Baxter, both of which contain sound information of a useful character. Much other matter is given, including reports of the shows held by the Association during January, February, and March, particulars relative to affiliated societies, and the excursion arrangements for the season. Mr. Leonard Brown, Brentwood, Essex, is the Secretary of the Association, and to him all communications must be addressed.

— LIVERPOOL AMATEUR GARDENERS' ASSOCIATION.—That the Liverpool amateurs are determined to keep up their reputation was evidenced by the largely increased number present at the Common Hall, Hackins Hey, Liverpool, on Thursday last. Prior to a paper on "Azaleas," by Mr. R. Pinnington of Roby, letters of regret were read by Mr. Cooper from the President, Mr. Isaac C. Glover, and Mr. J. M. Smyth, Secretary, both of whom were on the sick list. Mr. Pinnington said Azaleas were much liked and very useful, but many amateurs did not succeed with them. Good fibrous peat and sand, also careful drainage, were needed when repotting, the best time being just as the plants commence to grow. Large shifts were not beneficial, the soil being apt to get soured. Careful attention to watering, frequent syringings, and a moist growing temperature from 45° to 55° would get them into condition for setting their buds, the plants being benefited by a shady position outdoors during the later summer months. Syringing occasionally with soft soap and warm water would tend to keep thrips at bay. House at the end of September, seeing that the pots are free from worms, and do not overwater. A list of twenty-four amongst the best varieties was written and presented to the members, *Deutsche Perle* being recommended as an early white, and *Souvenir du François Vervaeue*, one of the most handsome whites in cultivation, for late work. The members had some interesting exhibits, Mr. Baddeley winning with Azaleas, Mr. Langley with *Dentzia gracilis* and one Fern, Mr. Redfern greenhouse flowers, Mr. Ardran handsome Roses. Mr. Drake had a pretty *Cattleya citrina*, and was awarded certificate for Cactus, the special prizes going to Messrs. Langley and Hoskyn. Several new members were proposed. Votes of thanks closed the meeting.

HOEING.

SURFACE cultivation of the soil includes hoeing, as amongst the most important operations. So needful, or rather essential, is this that it is worth the closest attention of all engaged in gardening, whether they are commencing or more advanced in their career. It well repays careful study, as few common tasks have so many interesting bearings upon soil condition and plant economy. Unthinking workmen too frequently regard hoeing as merely a ground-cleaning operation, placing it upon the same basis as sweeping a walk or cleaning a greenhouse; and certainly if it is done thoroughly even from this standpoint the whole purpose is fulfilled. A young gardener, however, who wishes to follow his calling in a manner creditable to himself and his employers, should not be content until he understands the objects and effects of every task he is called upon to perform.

In the destruction of weeds by hoeing the objects are not only to prevent soil exhaustion and the consequent injurious competition with legitimate crops, a matter of vast importance, but also to decrease the evaporation of moisture from the soil, which is greatly increased when it is occupied with vegetation either as cultivated plants or weeds. Any plant that exposes a large leaf area to the action of the sun and air absorbs an enormous quantity of water from the soil every day when in full growth, and under a hot sun a large proportion of this is immediately evaporated. Some years ago Dr. Stephen Hales conducted a series of interesting experiments in the evaporation of moisture from growing plants, and his results have furnished many subsequent observers and writers with valuable hints. The leaf surface of the plants employed was measured, and by a careful system of weighing the plants at different times the amount of moisture evaporated was determined. The following examples, all well known plants, will serve to indicate the results of these experiments, and the subject now under discussion:—

PLANT.	LEAF SURFACE. SQUARE INCHES.	WATER EVAPORATED IN TWELVE HOURS.
Sunflower	5616	20 ozs.
Cabbage	2736	19 ozs.
Vine	1820	5½ ozs.
Apple	1589	9 ozs.

Many weeds can almost rival the Cabbage in their leaf surface and evaporating powers. I have observed numbers of vigorous examples of common weeds with abundant foliage, that I have estimated to present a leaf-surface of 500 to 1000 square inches. When it is considered how closely weeds occupy the ground compared with cultivated plants, it will be seen that their moisture-evaporating powers are greatly increased.

Probably as regards all the smaller growing and surface-rooting, or annual weeds, the chief evil arises from their depriving other plants of the moisture they need; but deep-rooting weeds like docks and thistles also exhaust the soil of many important substances besides water. Those with creeping roots, like couch grass (twitch), and bell-bine also impoverish the ground; all such should be burnt and returned as a surface-dressing, for the double purpose of insuring their complete destruction, and the restoration of the mineral constituents of their ash to the soil. In the case of all weeds not bearing seed or increasing by their roots there is no doubt that the best means of turning them to advantage is by digging them into the ground, thus converting them into manure. But this is seldom practicable when the ground is occupied by crops, and in consequence we have to depend upon our friend the hoe for aid in their extermination.

But beyond the destruction of weeds hoeing affords material help to the gardener in cultivation, for surface stirring benefits crops greatly, as the majority know, though all may not understand the reason. When soil becomes "caked" and dried on the surface the minute passages between the atoms, termed capillary tubes, are innumerable, and through these moisture contained in the soil is absorbed from a considerable depth by the power of the sun, and it escapes just as it does from the pores in the leaves of plants. Many experimental scientists have directed their attention to this subject, and have shown what a large proportion of moisture is lost by evaporation compared with that which passes through the soil. The average of many observations on the Continent and elsewhere shows the following per-centage—i.e., 31·3 percolation to 63·2 evaporation. At Rothamsted the results of several years' observations give a nearly identical proportion, namely 36·8 percolation to 63·2 evaporation. In a series of experiments at Rothamsted extending over ten years the following records were obtained:—

MONTHS.	RAINFALL. INCHES.	DRAINAGE. INCHES.	EVAPORATION. INCHES.
April to September	16·364	4·393	11·971
October to March	14·673	9·096	5·577
	31·037	13·489	17·548

Any means that can be adopted to reduce this enormous evaporation must obviously be of great advantage, and experiments have proved that the practice of hoeing, even only as a surface stirring expedient, is correct and beneficial in every way. At the Storrs Experimental Station some comparisons were made a few years ago with regard to the effects of stirring on heavy and light soils and to different depths, the results being very marked in all cases. The method adopted was to fill cans 30 inches deep and 10 inches in diameter, evenly, and of the same degree of solidity as ordinary soil, and these were then placed in the ground so that the tops were level with the surface, thus being exposed to the same evaporating power as the surrounding soil. Four cans were devoted to each experiment, the heavy soil consisting of 20 inches depth of yellow clay at the bottom, the upper 10 inches being a heavy loam. The light soil had 10 inches of sand at the bottom, the upper 20 inches being light loam. The experiments were conducted during a period of a fortnight—namely, from August 15th to August 31st, when the weather presented an average-alternation of sun and cloud. The loss of moisture in the time named was as follows:—

	HEAVY SOIL. lbs. ozs.	LIGHT SOIL. lbs. ozs.
Not stirred	4 13	3 5
Not stirred	4 9	4 2
Stirred 2 inches	3 10	1 12
Stirred 4 inches	3 8	2 3

It will be seen that as regards the heavy soil the average gain was 1 lb. 2 ozs. of moisture by stirring, and with the light soil the gain was about 1 lb. 15 ozs. One advantage of facts like these is that they serve to impress upon young minds the importance which attaches to quite ordinary work, for in hoeing the continuity of the capillary tubes is broken and the loosened surface soil becomes a kind of non-conducting layer, which may be said to serve in a measure the same purpose as mulching. I remember once visiting a celebrated Strawberry garden, which, to my surprise, was little better than a sand bank, and it perplexed me how such a moisture-loving plant could be not only kept in healthy condition, but made to yield abundant crops of fine early fruits in such a soil. It is possible that it contained naturally some substances beneficial to the Strawberry, but beyond this the owner attributed a large measure of his success to the frequent use of the hoe between the rows, especially in dry weather.

In my own experience I have seen results from hoeing as surface stirring only that were equally surprising, and in some cases it has produced even more effect than an application of manure. Heavy soil that is liable to crack in prolonged dry weather is much benefited by the use of the hoe, for with cracks in the soil an inch or more in width and a couple of feet deep it can be imagined what moisture must escape by evaporation. Timely hoeing not only prevents a large portion of this waste, but it prepares the soil to receive the rain when it comes, and enables plants to secure the maximum of advantage such supplies should yield.—PRACTITIONER.

LATE TULIPS AT LONG DITTON.

My second visit to Messrs. Barr & Sons' bulb grounds near Surbiton was under very favourable weather conditions, for not only was the air warm, but the sun shone out gloriously, and created in the masses of Tulips seen on every hand a harmonious response.

What marvellously rich as well as beautiful colours Tulips give, but especially the lustrous selfs, for these, without doubt, create the finest effects outdoors, whether in clumps or masses; the most brilliant ones, which however florid when near, viewed from a distance giving colouration as beautiful to look upon as is the fiery setting sun on a wintry afternoon.

Of all bulbs the Tulip is undoubtedly the richest in colour, as well as varied in shade or hue. Striking as are the early Dutch varieties, the late ones, and especially the singularly beautiful Darwin forms, excel in variety as well as in delicacy of tint or colour. If, as a rule, the flowers are less in size, they are borne on rather taller stems, and in that respect are so beautiful. When cut early for vase decoration they keep in a cool room for a fortnight. Their greater height also gives them a more commanding aspect, and if blooming best in May, they do so under more acceptable conditions, for the weather in the later month enables flowers to be more completely enjoyed.

Very many persons have to make acquaintance with these Tulips only at exhibitions, and then usually in dull light, and in mere handfuls; but the few who can get to Long Ditton see them, especially on a bright sunny day, in their glory. If Solomon in all his magnificence were yet not arrayed like to the Lily of the fields, how would he have compared with a late self Tulip of any hue or marking? Really they seem to be flowers of the gods, the

goblets from out of which they in metaphor quaffed the nectar of Olympus.

How strange is it that with such beautiful models as these flowers present, yet our artificers in rich metals seem never to have fashioned goblet, cup, or tankard to resemble a glorious Tulip. Judged by purely garden ideas, the flaked bizarre and bybloemen flowers so much loved by the florist, and of which there is at Long Ditton so fine a collection, are not in a mass so effective. They need individual examination, and those who have the true florist's mind see in them markings of wondrous beauty and excellence. Of these I took no note; they are best dealt with by those who know them. In the beautiful section known as Darwin's there is such a wealth of colouration, self-shaded and parti-coloured, that it is hardly needful to look farther; but there is none the less outside of these infinite variety.

One of the first I noticed, and it was found in great quantity,

purposes, being once planted, the best Tulips for late blooming that exist. Those I specially noted, though all were good, were:—

CARMINEA.—Rich carmine rose, approaching magenta, shaded carmine.

ERGUSTE.—Bluish heliotrope, the nearest shade of blue seen in the collection. A very lovely Tulip.

CORDELIA.—Purple shaded blue, with a rose tint; is equally charming.

DOROTHY.—A bluish mauve tint, shaded white, or in some flowers giving a shade of creamy rose.

EARLY DAWN, rosy lake, shaded blue. These descriptions suffice to show what rare tints are to be found in these Tulips.

GLOW, one of the rich fiery brilliant vermilions that can be seen so far off.

FIREBRAND, a real fiery furnace of colours, is even more intense than the preceding.

FIG. 84.—THE FERNERY AT AVERY HILL. (See page 407).

was Picotee or Maiden's Blush. The flowers in the early stage are creamy white, becoming white as they enlarge, then showing a narrow edging of rose, which, as the flowers age, becomes much broader, and presenting in each phase singular and refined beauty. Near by was a large bed of Golden Beauty, rich deep orange yellow, of rounded, handsome form, and strikingly effective in bulk. A grandly coloured Tulip, too, is macrospila, rich crimson scarlet with black base, very fine for massing. Even more fiery in colour is Didieri, a rich vermilion crimson, that glows in the sunlight with marvellous effect. Didieri lutescens is a pretty primrose yellow, and Didieri alba a soft creamy white slightly edged with rose. The Gesnerianas are, of course, prominent, especially *G. spatulata*, of intense crimson scarlet hue, the flowers large and massive; and *G. rosea*, deep rosy carmine, very lovely.

In a huge cluster of beds are the Darwinian section, but there is about them nothing of the monkey or the grotesque. Generally the flowers of this singularly beautiful class, of which there are over two dozen varieties, are well borne above the foliage, and excellent in form, though not large. They seem to be for garden

LOVELINESS, a variety that is aptly named; colour soft satiny rose, of exquisite beauty and rather taller.

MAY QUEEN, of a soft rosy lake, a charming form.

ZEPHYR, another of the heliotrope hues, having a bluish shade; flowers bold and erect.

PHYLLIS has flowers of a delicate white, shaded rosy lilac.

SULTAN is the darkest of all. The outer petals are purplish maroon, the inner ones almost black. It is a very distinctive and marked variety.

SCARLET BEAUTY.—This makes a dozen, and is scarlet shaded orange, a very beautifully formed flower, and of striking appearance.

Of others in quantity very noticeable were Blushing Bride, white striped, and feathered scarlet; and Royal White, very pure and fine. Many of these Tulips are now comparatively cheap, and among those that are more expensive it must not be forgotten that they, if well cultivated, increase from year to year, and three bulbs soon expand to a dozen.

To leave them in the ground [all the] year [round] untouched

is hardly fair treatment, although in many gardens they are so treated, and they bloom well; but if the roots be lifted during the summer, properly dried, then stored in a cool dry place, and replanted in fresh good soil in the autumn they will repay the treatment, whilst the offsets grown separately the sooner become flowering bulbs.—A. D.

[We have seen the Talips referred to by our correspondent, and confirm his choice. Apart from the effective "Darwine," the trio, macrospila, Picotee, and Golden Beauty, would be difficult to excel for flowering in masses in May.]

THE FLOWER GARDENS OF VICTORIA (AUSTRALIA).

MOST people I have met in England seem to have an idea that Australia is a scorching sun-baked land, ever thirsty and parched, and seem filled with incredulity when told that it can grow the lovely flowers and plants that it does. Now this state of things is much to be deprecated and wondered at, for with so many hundreds of persons passing between England and Australia every week, it is time the folk here had a brighter, pleasanter, and at the same time more correct idea of the place they may be merely going to visit, or perhaps think of making their future home, so that when they bid farewell to this fair land they may not leave with a sense of saying "good-bye" to all that goes to make up an English home, and especially an English garden.

However, I shall endeavour to give you a layman's ideas or remembrances of average gardens in and around the suburbs of Melbourne, and in certain country districts where it has been my good fortune to have been, when I had a good opportunity to judge how imported flowering plants behave in their adopted country. I propose first of all to give some slight idea of our climate in the colony of Victoria, as a preface, so that you can understand some of the external conditions under which our plants and flowers grow.

Briefly then, we have two very warm months—viz., January and February. These form our midsummer. Beginning to get warm in November, December gradually becomes warmer as the days slip by. Flowers and shrubs commence to wear a jaded look. January comes along, and we find this condition increasing until in February the thermometer generally reaches its highest point, which varies according as the season be a mild or severe one, as in any other part of the world. Now the gardens and country generally look distressed, the earth is baked hard, and Nature, save in some instances, appears worn out with struggling against long odds, and is only saved from downright death by a timely change and a good shower, which puts enough vigour into plant life to sustain it. Of course, by the plentiful application of hoses and sprinklers, for the use of which there is a small tax, hundreds of gardens are kept in proper state, and the dews at night, along with this and the humid atmosphere make things grow in a semi-tropical manner.

Then again the heat is not continuous, and sudden cool changes occur after a few days' heat; rain falling, the earth is cooled, and it seems as if these changes were sent to keep things going. But alas! in many places inland the long-looked-for change may not come for weeks or months, and then comes a drought, which seem to recur periodically. I am, however, speaking of places which are within 100 or 200 miles from the coast, and not too hot for the aborigines. So, to sum up the summer—it is a very warm or hot season, the temperature going up at times to 105° and 106° at rare intervals near the coast, with an average of about 90° F., varied by several cool days together and a recuperation. For instance, we read of the present summer of birds dropping down dead off the branches from the great heat, and then a few days later so cold that all are wearing winter clothes and are burning fires in their houses. One thing I have forgotten to mention, and that is the burning north winds, which, blowing from the sun-baked interior, swoop down over Melbourne and suburbs, parching up everything for the time being. Strange to say these are becoming of less intensity, and do not last as long as in the earlier times, a phenomenon evidently due to civilisation and alteration of the surface of the country.

At length in March a change begins to be appreciable. Hot days grow less frequent, and autumn creeps on apace. Lovely days with gorgeous sunsets become the order of the season, and April sees the first of the wintry rains, but not till May is well upon us do we get the cold weather. Rains are frequent and wet days plentiful, and the earth seems to have taken a new lease of life. In June we have the true winter weather. Cold, clear, sharp nights, rain, hail, and frosts, and last year snow fell heavily. Growth is, of course, slow, or arrested almost, and not till July is gone and August is with us does the earth seem to re-awaken and respond to the voice of spring.

Many of these winter days are lovely in the extreme. Perhaps fogs (but not of the smoky London sort) and frost at night, cold, sharp mornings, but lovely sunshiny middays and afternoons. Days in which one loves to bask in the warm sunshine and enjoy the clear atmosphere with a sky as blue as that of Venice. These are the days one feels glad to be alive, for they are charmingly exhilarating.

The end of August and beginning of September sees the plant-life awakening everywhere. Plants can almost be seen to grow in the humid air and soil; all the fruit trees leaf and blossom; the grass and Cape weed, introduced by the late B. Von Mueller, with its lovely composite bright yellow flowers, are a treat to behold; and now, where once hard-baked clay was to be seen, with not a trace of verdure, there spring up, as if by magic, all sorts of flowering grasses and weeds, which seem to fairly revel in their new existence. Gardens are in their gayest attire, and need lots of weeding and cleaning. This continues until the end of October, when the first faint hot breaths begin to be felt, just sufficient to remind the flowers that their time of trial is coming. So we come round to the warm summer days again in November.

I shall now speak of the gardens and their occupants in these respective seasons, trying to put a mental picture before your eyes, a picture as seen and described by one who is pleased, as an amateur, with the scene, and tries, however imperfectly, to describe it to you, who may in comparison be looked upon as true artists.

Beginning at the commencement of summer—viz., in November—one finds the gardens looking very gay and full of freshness. Geraniums of all sorts grow and bloom in great profusion. Columbines, Foxgloves, and some late Freesias, Cowslips, Primroses, Polyanthus, and other late spring bloomers are growing almost if not quite as well as in any English garden. Auriculas are less common, but are cultivated in the higher altitudes to great perfection. Pelargoniums make a splendid array, and grow in almost any locality to the verge of wildness and in the greatest variety, the fine pink one known to us as the "Azalea." Pelargonium being especially fine and a free grower, blooming well in the hottest weather. Carnations are in almost every garden, and are remarkably fine, a large delicate pink one being a general favourite. The White Prince and the Clove-scented dark crimson share this honour also. I have seen nearly an acre of these lovely scented plants in one nursery, the perfume from the flowers being exquisite. Petunias thrive amazingly, and with a minimum of attention. Whites, purples, pinks, single and double Phloxes are easily grown, and afford an immense variety of colour.

Pansies and Larkspurs can be kept blooming nearly all the hot weather with very little care, while Ericas, Epacris, and Heaths are plentiful and of all varieties, the Australian climate seeming particularly suited to them. Many varieties are indigenous, and may be found in the wild state in many places in New South Wales. Irises do well, and make a splendid show in the earlier summer months, the Japanese Flag Irises being particularly fine, with their handsome foliage and large Clematis-like flowers, both single and double, and from 5 inches to 7 inches in diameter, varying in colour from the darkest blue to rose, salmon, red, purple, crimson, pure white, orange-yellow, striped and blotched. Our climate is also specially suited for the Amaryllis family, and they require little care, and the flowers of white, rose, vermillion, maroon, and purple are a treat to see, so well do they blossom. Tecomas, Sweet and Everlasting Peas, require plenty of water and looking after. Balsams, Gladioli, Dahlias, Cockscombs, Asters, Marigolds fairly blaze in the bright sunlight. In fact for the latter flower the heat seems to be essential for the proper development of the blooms, and a border of these on the lawn at our big racecourse at Flemington on the day of the running of the Melbourne Cup race has gained a world-wide fame for its lovely sight. Fuchsias, Pentstemons, Foxgloves, Hollyhocks, Zinnias, Coreopsis, Cinerarias, Stocks of all hues, single and double, bloom well, but require plenty of hose and attention.

When summer is at a white heat, so to speak, and many gardens are looking a little seedy, those who have planted Mesembryanthemum and Portulacas are well repaid. It is a fact that the hotter the day the better do these bloom. The former grow wild on all the seacoast cliffs, and when in a garden and cared for are simply dazzling in brilliancy. Golden yellows, pale crimsons, and snow whites, all look at their best, and their icy-like thick leaves have a cool appearance. Nasturtiums also seem to revel in the heat, the leaves growing as large as good-sized dinner plates, and on any fence or wall this beautiful plant grows ranker than a weed, and the strange admixture of colours, due to the bees, I believe, presents an ever varying sight, while the green leaves are a delightful rest to the eyesight in days almost too bright.

Again I must sing the praises of a favourite flower of mine. I refer to the double Pink or Ivy-leaved Geranium. This plant makes the poorest garden look gay in the hottest months, and will grow in almost any place where a piece is thrown simply on the surface in the spring. I have seen several fences converted into what were seemingly hedges, and in one back yard in spite of fowls and pigeons laying and making their nests in it, I have seen it all through the summer just one blaze of lovely delicate pink. Its long stalks grow through the green foliage, and blossom in huge clusters. If the pale blue Plumbago is here and there planted with it, the effect is most artistic, for this also grows splendidly. Indeed, in one of our public gardens round the Melbourne Treasury offices I have seen it in a long neatly clipped hedge some 5 feet high and full of blooms.—(Read by DR. ERNEST D'OMBRAIN of Melbourne at a recent meeting of the Horticultural Club).

(To be concluded.)

CHEMISTRY IN THE GARDEN.

(Continued from page 312.)

THE fertility of soils depends to a considerable extent upon their physical properties. The presence of sand, clay, humus, and carbonate of lime has a great deal of influence in determining the physical condition of soils, for each of these proximate constituents possess different properties, and consequently the character of a soil will depend to a considerable extent upon which of them predominates.

THE PHYSICAL PROPERTIES OF SOILS.

THE WEIGHT OF SOILS.—On page 312 we gave the analysis of three soils in parts per 100, or what is termed the percentage composition—i.e., every 100 lbs. of soil contains so many pounds, or parts of pound's weight of certain substances. We find on weighing equal volumes of different kinds of soil that the weight of each varies considerably. Thus the approximate weight of—

1 cubic foot of dried sand	is from	110 to 120 lbs.
1 " " loam	"	90 to 110 lbs.
1 " " clay	"	70 to 80 lbs.
1 " " leafmould	"	55 to 60 lbs.
1 " " peat	"	40 to 55 lbs.

It is very important to remember in considering the amount of plant food, as shown by the analysis of a soil, that although a sandy soil may look to contain less nitrogen, potash, phosphoric acid, and lime than a clay, it may, nevertheless, be the richer soil owing to its greater weight. To illustrate this fact let us take, for an example, two soils, each showing by analysis the same amount of phosphoric acid—viz., 0.20 per cent. The top 9 inches of an acre of a sandy soil would weigh about 3,500,000 lbs., and at 0.20 per cent. would contain 7000 lbs. of phosphoric acid; while the top 9 inches of an acre of a clayey soil would only weigh 2,500,000 lbs., and contain, at 0.20 per cent., 5000 lbs. of phosphoric acid.

The term *heavy* is often applied to a clayey soil, and *light* to one that is of a sandy nature. This is not literally correct, as may be proved by referring to the above table. The term heavy as applied to clayey soils is used to denote that they are stiff, tenacious, and heavy or hard to dig; while sandy soils are called light because they are open, porous, and light or easy to dig.

TEXTURE.—The texture of a soil will depend upon whether its particles are large or small. A soil which is made up principally of coarse particles of sand, chalk, or stones, possesses little cohesion, its particles are large and loose, and such soils will be of an open, dry, and porous nature. If the particles of soils are very minute the land will be of a close tenacious character, plastic and sticky when wet, hard and lumpy when dry. Soils are very deceptive when their particles are in a finely divided state; thus many sandy soils may be mistaken for clays, a good example of this being the brick earths near London. Chalk is of an open, porous nature when its particles are moderately large, but when finely divided it possesses a sticky and retentive character.

HEAT OF SOILS.—Nearly the whole of the heat of soils is derived from the heat rays which are given forth from the sun. When the sun is shining upon soils they absorb some of the heat rays, while others are radiated into the air. Some soils absorb more heat rays than others. In a series of experiments conducted by Durocher he found that when the temperature of the air was 90° F. a thermometer placed 1 inch below the surface of different soils exposed to the sun gave the following results:—Quartz sand, 126° F.; garden soil, 115° F.; yellow sandy clay, 100° F.; chalk soil, 87° F. This shows us that a sandy soil is able to absorb a very large amount of the sun's heat, while a chalk soil is scarcely influenced at all by it. Quartz sand has the greatest power of conducting heat of all constituents found in the soil, the worst conductor of heat being air. Sandy soils, by being open and porous, will contain much air, and although they may get very hot at the surface the heat will not penetrate to any depth into them. Consolidation and the presence of stones improves the conductive power of soils. A dark coloured soil when the sun is shining upon it becomes hotter than a light coloured one. This is shown by the fact that when the temperature of a garden soil was 115° F. a chalk soil exposed to the same amount of sun heat was only 87° F. The dark colour of soils is generally due to the presence of humus, and the light colour to the presence of carbonate of lime or chalk. It is very interesting and instructive to watch the rapid growth of crops growing on dark coloured soils, while crops growing under exactly the same conditions on light coloured soils seem scarcely to make any progress.

The presence or absence of water chiefly determines the cold or warm nature of a soil. The heat required to raise 1 lb. of water would raise 5 lbs. of quartz sand to the same temperature, consequently it requires more sunshine to warm a wet soil than a dry one. Wet soils are also cold because the heat, instead of warming

the soil, is used up in evaporating the water from it; for if 1 pint of water is evaporated from 100 lbs. of soil the soil will be left 10° F. colder than if the water passed away by filtration. Drainage is, therefore, the only cure for a cold wet soil.

Slope or inclination has considerable influence on the temperature of soils. Suppose we have three soils—one sloping towards the sun, one horizontal, and one sloping away from it. The first of these would absorb more heat than either of the others. The

Fig. 85.—S, Sun; R, Heat Rays; SL, Slope of Land, (1) towards the Sun, (2) horizontally, (3) from the Sun.

reason of this is that the same amount of heat rays which fall on a certain area of land sloping towards the sun, will cover a wider area of land lying horizontally, and more so on land which slopes away from the sun. This is shown more clearly in the illustration (fig. 85). It might be thought that the rays would diverge, but owing to the great size of the sun, and long distance from the earth, the heat rays which reach us are always parallel.

THE HYGROSCOPIC POWER OF SOILS.—By this term is meant the power soils possess of absorbing moisture from the air. It is a well known fact that if dry salt be exposed to the air it becomes damp. The salt has attracted moisture from the air, and is, therefore, said to be a hygroscopic substance. Soils are to a certain extent hygroscopic substances, but the amount of moisture absorbed is almost insignificant. Schübler found by exposing different kinds of soil for twenty-four hours to damp air, they absorbed the following quantities of moisture:—

1000 lbs. of ploughed land	absorbed	23	parts of moisture.
1000 lbs. of clay soil	"	28	" "
1000 lbs. of loam	"	35	" "
1000 lbs. of heavy clay	"	41	" "
1000 lbs. of garden soil	"	52	" "

It is doubtful if the hygroscopic power of soils is due to the state of division of the particles, it being more probably owing to the presence of certain chemical substances in the soil, such as silicates and hydrated silicates of alumina, and also to certain salts.—W. DYKE.

(To be continued.)

OUR GARDEN.

TIMES were when revelling in the unqualified pride of possession our whims and fancies were studied by old Job, plus the orthodox routine in which his soul delighted. Old fashioned to a fault was the worthy man. Peace to his ashes, while we enjoy pleasant memories of the past. The fact that another gardener was wanted brought keenly home to us that we were old fashioned, too, by solicitations shown by lady friends that the new man should be different from the old. "Really, Squire, you know no gardener of to-day would tolerate such a muddle as old Job delighted in; you are quite behind the times." It was surprising how many gardeners wanted gardens just at that time, and yet what a task it was in choosing the right man for the right place.

"So glad, Squire, you are suited; just the man, I should think; now you will see a change." Prophetically true were those words. We have seen the old landmarks disappear, some abruptly, others stealthily, till a visitor desiring to be complimentary remarked—"The garden is so changed one would hardly know it." "One at least knows it, and regrets it," was it is feared a grumpy comment. Still the fair enthusiast persevered, "Oh! but you know, Squire, you like hardy flowers, and see how vastly X has improved the long border." It is so, alas! for most of our old favourites are improved out of existence, and in their place are the new "old-fashioned" flowers, none of which we dare gather, and many of which we cannot smell. What a soul there used to be in that long border in the early summer mornings; now it is scentless—soulless. "A wonderful collection." Yes, it is admitted; some capped with glasses because they are "miffy," others collared with zinc because they

are beloved of slugs and other beasties, and placarded with such names as should deter all evildoers of the vermin tribe.

For years there were but few beds in the greensward under the windows in which old Job set out his scarlet Geraniums, but eventually, and with infinite pains and labour, it seemed as if the drawing-room carpet had been run out over the whole space for a summer airing, then taken up, unravelled, and "boxed" for storage in our limited glass houses. "Not nearly enough glass." No; old favourites collected from far and near are relegated to obscure and crowded corners. Now and again old associations tempt us to bring home a few slips of common things, and we had a little weakness for potting or planting them ourselves, until the hint that a gentleman's place was not in the potting shed brought that pleasure to an end. Old Job used to take rather a pride in pandering to these tastes of ours, and his life was not made the less happy by so doing.

There is no reason to doubt that our new gardener was a very clever man. Mr. X's bedding out, his fruit, his flowers, his house were freely expatiated upon by enthusiasts. Ah! "his;" it used to be "the Squire's." Yet, though his ways were not ours, we would fain have kept the partnership intact, in the hope that by mutual yieldings we could as master and man have shaken hands across the narrow border of our difference; but this was not to be, and the end of it was that X. decided to go where, as he said, "his ability would be appreciated;" and he went—into a nursery. There he let chance after chance pass as "not good enough," till he gradually subsided into the jobbing staff, and now spends much of his time in "doing up" suburban gardens.

Changes, somehow, do not suit old-fashioned folk, least of all old-fashioned gardens. We have, I fear, been spoiled by old J, whose strength laid in our weakness, whose aim in fruit and vegetable growing was to provide the best of what we, not he, thought good, and whose eyes beamed with delight when, unasked, we sampled *our* fruit on the spot. Those were the days when our garden was to us a paradise of delight. We are trying to get it back to the past, but fear it will never be quite its sweet old self again.—THE SQUIRE.

ROSE SHOW FIXTURES FOR 1897.

- June 7th (Monday).—Cambridge.
- " 9th (Wednesday).—Chelmsford.
- " 15th (Tuesday).—Ryde.
- " 16th (Wednesday).—York.†
- " 18th (Friday).—Portsmouth (N.R.S.).
- " 23rd (Wednesday).—Richmond, Surrey.
- " 24th (Thursday).—Colchester.
- " 25th (Friday).—Maidstone.
- " 26th (Saturday).—Windsor and Dorking.
- " 29th (Tuesday).—Canterbury, Hereford, Sutton, and Westminster (R.H.S.).
- " 30th (Wednesday).—Croydon, Ealing, Farnham, and Reading.
- July 2nd (Friday).—Crystal Palace (N.R.S.).
- " 7th (Wednesday).—Glasgow, Hanley,* Hitchin, Reigate, Leeds,† and Tunbridge Wells.
- " 8th (Thursday).—Bath, Gloucester, Harrow, Newcastle-on-Tyne,† and Woodbridge.
- " 13th (Tuesday).—Wolverhampton.†
- " 15th (Thursday).—Norwich (N.R.S.) and Helensburgh.
- " 17th (Saturday).—New Brighton.
- " 22nd (Thursday).—Halifax and Trentham.
- " 27th (Tuesday).—Tibshelf.
- " 28th (Wednesday).—Chester.*
- " 31st (Saturday).—Liverpool.*

* A show lasting two days. † Shows lasting three days.

The above are the only dates that have as yet reached me. I shall be glad to insert in the next list any further fixtures that may be sent me, whether of Rose shows or of horticultural exhibitions where Roses form a leading feature.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

THE MALEVOLENT WEEVIL.

It must be more than twenty years ago that I wrote to the Journal, enclosing a beetle that had done much harm to my Roses and a good deal to my peace of mind, and learnt that its name was *Otiorhynchus*. It is not a very easy name to remember or to spell, but I remembered it, for I thought it suitable. It sounded like a "bad name," which the creature fully deserved. I have never, I am glad to say, come across a human being who merited such abuse; if I did, the words "Oh, you *Otiorhynchus*, you!" would mean a good deal in my mind—the malevolent weevil, which loves doing evil.

This creature, a little brown long-nosed beetle, whether *O. picipes* or *O. sulcatus* I don't know or care—they are "birds of a feather"—makes it his work and delight to come out by night and gnaw away and completely destroy the inserted Rose buds in standard stocks towards the

end of April, just when they are delighting the heart of the badder by showing signs of growth.

Those who do not know the enemy are often much puzzled, as no sign of him is to be seen in the day, and even at night with a good light he is not very easy to find if you do not know his "tricks and his manners." Now why I attribute to this creature a pure love of evil is because I have never found it or seen its work on a cut-back, where it could only spoil a bud, but solely on budded standards, where it has a chance of destroying the whole plant. I have fancied that it has a preference for a stock which has only one bud, but have not been able to establish this.

Having had a severe visitation of these weevils this spring, after several years' immunity, I think I have discovered the sort of place where they hide by day. It is generally said that this is in the ground, but I do not think so; I have never had any plant attacked that stood well out in the open, or at all events but rarely—the worst attacks have always been at that end of a row or bed nearest to an old rubbishy or ivy-covered wall. Five plants were utterly destroyed before I was aware of the attack, and I visit my plants pretty often, and we have caught in four nights about four dozen of the enemy.

The stocks were planted and budded where I have never had Roses before, reaching almost up to just such an old wall, and the plants nearest the wall were almost invariably those attacked. I have actually found the creatures in the daytime on the wall out of the light, and on the wall in a little outhouse near, and under rubbish on the floor. I should think it likely that in a good open piece of ground they would be almost unknown.

Many a rising amateur, however, has to plant his stocks in just such sorts of unused corners. Let him be forewarned, and in April watch his buds daily, and at the first sign of attack go at night with a lamp. He will find most on a warm night, but some, if the attack has begun and the enemy are numerous, even on a frosty night. Let him look over the whole plant carefully, stem, bamboo stake and all. No difficulty in catching them with a sure finger and thumb, and taking care not to jog the plant; if they once fall it is very hard to find them.

Surely there is no insect Rose pest like this, which will absolutely destroy a whole plant just at its most hopeful stage in a single night; and I think I may well class along with the scoundrel sparrow (which has just got the whole of the little Apple blossom that formed on my trees) the malevolent weevil.—W. R. RAILLEM.

PROGRESS WITH MARÉCHAL NIEL.

I HAVE much pleasure in sending you some cut blooms of *Maréchal Niel* Rose. I do not know whether they deserve commendation or not, but from the surprising growth of the plant I thought perhaps your readers would be interested in a few remarks which I would like to add. I purchased a very insignificant plant some seven or eight years ago, and having no glass at the time, it was placed out of doors, but it only appeared to make progress in a retrograde direction, which was exceedingly disappointing. The foliage was very scanty, and about the size of finger nails, and the stems were about the thickness of 16 or 18-gauge wire. After I had a house erected I placed the plant in a 14-inch pot, which I buried in the corner of the bed, where it had the morning sun. To my surprise the degenerate Rose made rapid progress in the desired direction, and in a very short time I was able to discern whether it were a Rose or not. I kept it in the pot until last autumn, when I thought that perhaps there was too much accumulation of roots, and that they had insufficient room to nourish the now extensive growth. When I cracked the pot and removed it I found that the roots had worked round and round the interior, and were like so many hoops. These were cut away, and a good foundation made to receive the plant again. Last season I counted upwards of 250 blooms on it, but this year it has not done so well, owing to its being disturbed in the autumn I suppose. It now entirely occupies the roof of a house, 12 feet by 8 feet, and the main stem at the base is about the diameter of an ordinary 60-size pot.—H. M. MILLS, *Pontardulais*.

[Considering the bold treatment of the roots (which but for others taking a downward direction would have ended disastrously) Mr. Mills has good reason to be proud of his *Maréchal Niel*. Its first progress in a "retrograde direction" reminds of one of the armies in Thessaly taking up a "more favourable position in the rear"—a delightfully euphonious way of describing a retreat. The army, we think, did not make "rapid progress in the desired direction;" but the Rose, judging by the "finger-nail" test (which is a new one), has evidently made a great advance. The foliage sent with the blooms is not "scanty," but plentiful, and the leaflets would represent finger-nails $2\frac{1}{2}$ inches in diameter. We have seen larger (not nails, but leaves, and these are large enough), also we have seen larger blooms, but never heavier for the size. Those before us are unusually full and symmetrical, rich in colour, and altogether excellent. They seem to have brought into the suburban sanctum a sniff of the sweet air of South Wales. This it is hoped does not represent "retrograde progress" in alliteration, and Mr. Mills is thanked for the beautiful blooms.]

PLANTS FOR A SHADED WALL.—Will some of your correspondents kindly advise as to what can be done to cover the back wall of an *Auricula* house, facing N.N.W.? It is 13 feet long and 6 feet high, and the sun never reaches it. Ferns no doubt would grow, but would the airy dry atmosphere, suitable for *Auriculas*, be injurious to the Ferns?—T. L. C., *Birkenhead*.

CYPRIPEDIUM LAWRENCEANUM.

AMONGST the many plants, both flowering and foliage, that are so admirably grown at Syon House, none looks better at the present time than this handsome Orchid, with its bold flowers and ornate leaves. There are some dozens of plants occupying a front stage in one of the houses, and the spectacle is magnificent. Each individual specimen is in perfect health, and is producing astonishing numbers of flowers. Syon and Mr. Wythes are justly celebrated for their vegetables and fruits, but it is none the less a fact that such *Cypripediums* as the one named, with others, besides *Cattleyas*, *Odontoglossums*, *Dendrobiums*, *Vandas*, grand *Cymbidiums* and *Lælias*, the collection of Orchids is in such condition as would be no disgrace to a specialist in their culture who grows nothing else. No structures have been specially erected for them, and big sums have not been expended in their purchase. They are housed with other plants, and must give a good return for the space they occupy and the time spent in attention to them, or they would have to go to the wall, and this, so far as can be seen at the present time, is not likely to be yet awhile.—WANDERER.

NOTES ON AERIDES.

JUDGING by descriptions given by collectors and the appearance of newly imported plants of this genus, there are not many Orchids that can be so improved as these by carefully considered culture. We are told that the plants in most instances are straggling-looking, bare of foliage along yards of length of stem, and though flowering freely, not by any means so ornamental as a well-cultivated specimen. This, of course, is in a measure true of all species, but all species have not the same noble appearance when out of flower as the various plants comprised in this and the somewhat similar genera *Saccolabiums* and *Vandas*.

Unfortunately they have been for a long time much neglected by orchidists, but given plenty of room for their full development there is no other section in the order more truly ornamental. Take a large, well grown and flowered plant of *A. Fieldingi*, its immense racemes pushing out in all directions, backed by the striking and beautiful dark green foliage, and no one will fall out with you for calling it a thing of beauty. Even the old *A. odoratum*, the species upon which the genus was founded over a hundred years ago, and one of the cheapest and most easily grown of all Orchids, is still one of the most charming.

One drawback to the culture of large specimens is the space needed for them, and this has doubtless led many to discontinue it. But in several places there are vineries almost empty during the summer months that would make capital homes for them with no detriment to the Vines, while small plants of most of the kinds look well and flower freely suspended from the roof of the ordinary Orchid house. In the usual plant stove, too, they may be accommodated, and in any of these positions will not fail to give a good account of themselves at their proper flowering season. But the best of all places is a large spacious structure kept up to a moist tropical temperature and not unduly shaded.

Here growth will be free, but the foliage will be to some extent consolidated as it is formed, and by a gradual reduction of the temperature as winter approaches, and a corresponding rise in spring, the plants will keep to their annual cycle of growth and rest. This is far superior to the old-fashioned plan of drying off—copied no doubt from Nature, but still very unsatisfactory in practice. There are many ways of growing *Aerides*, the plants taking as a rule with a good will to whatever is provided as an artificial rooting medium.

Being true epiphytes, it was formerly the custom to give a bare root run over large blocks or some description of pottery ware, but this treatment is too poor to obtain the best results. Sphagnum moss is the best material to use, as it holds ample moisture for the needs of the plant, while if kept in proper mechanical condition by the addition of plenty of large rough lumps of charcoal and potsherds it cannot settle down to a close inert mass. The receptacles will vary in size with the different species. For instance, no one acquainted with Orchids would think of potting *A. odoratum* and *A. roseum* under similar conditions.

The former being a much larger habited kind would need more room and a very rough compost, the latter a small pot or basket, and the rooting medium in ratio with its size. A slight

difference in temperature should also be allowed, those species coming from the higher mountainous part being kept cooler and more airy than the inhabitants of lower altitudes. Root moisture is a point needing consideration, for although the Orchids named are nearly aquatic in their needs during the time growth is most active, a considerable lessening of the supply is necessary when both root and top growth are quiet.

The odoratum section comprises some very beautiful plants, one of the best being the splendid *A. Lawrencei*, a plant worthy of the greatest care. It has longer racemes and more brightly coloured blossoms than *A. odoratum*, and was introduced from the Philippine Islands by Messrs. Sander & Co. in 1883. The typical

FIG. 86.—AERIDES VANDARUM.

odoratum is too well known to need description, and *A. suavisimum* differs from it in having smaller flowers of a pale lilac tinge produced about a couple of months later in the year. *A. virens* has been described as a poor form of *A. odoratum*, but this is hardly true of some of the best forms. It is, however, a very similar plant, and was introduced from Java in 1843.

The beautiful *A. Fieldingi* flowers in May and June, and is known as the "Fox Brush" *Aerides*, owing to the gracefully curved racemes of flowers. It is one of Messrs. Veitch's introductions, their collector, Mr. T. Lobb, having sent it home in 1850. *A. crispum* is a fine species, not so large in habit as some of the preceding, but producing elegant racemes of large fragrant blossoms; and *A. crassifolium* is another favourite kind that should be grown by all. *A. Vandarum* (fig. 86) is totally different in habit and flower, bearing cylindrical leaves, and short few-flowered racemes, after the style of *Vanda teres*. It does with less heat than some other species, being found growing naturally high up on the Himalayas.—H. R. R.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL, MAY 11TH.

THE meeting at the Drill Hall was a very interesting one, though not so large as several have been of late. Each Committee had work to do, but as usual the bulk fell to the Floral.

FRUIT AND VEGETABLE COMMITTEE.—Present: Philip Crowley, Esq. (in the chair); with the Rev. W. Wilks and Messrs. T. F. Rivers, J. Cheal, G. Bunyard, J. H. Veitch, A. F. Barron, A. H. Pearson, W. J. Empson, A. Dean, J. A. Laing, W. Bates, W. Farr, G. H. Sage, G. Wythes, Jas. Smith, H. Balderson, G. T. Miles, F. Q. Lane, G. W. Cummins, G. Reynolds, J. Willard, R. Fife, and G. Norman.

Mr. W. J. Empson, gardener to Mrs. Wingfield, Ampthill House, sent a splendid collection of vegetables, comprised of Peas in pots Carter's Lightning, Leek Holborn Model, Tomato Earliest of All, Cucumbers Rochford's Market and Blendworth Perfection, with Asparagus, Broccoli, Potatoes, French Beans, and so forth. Considering the time of the year the exhibit was one of exceptional merit (silver Knightian medal).

Mr. G. Wythes, gardener to Earl Percy, Syon House, sent a collection of Figs St. John and Brown Turkey, and also a box of very fine well-coloured fruits of Hale's Early Peach. Mr. Jas. Barkham, Longford Gardens, Isle of Wight, sent fruits of a Cucumber the result of a cross between Rochford's Market and Improved Telegraph. Mr. M. Russell, Mytchett, Farnborough, sent fruits of Strawberry Russell's Early Giant, a fruit of a very wrinkled surface. Mr. A. Bishop, Westly Hall Gardens, Bury St. Edmunds, sent a specimen of a seedling Melon which, considering the earliness of the season, was of good flavour and large in size.

In the Apple competition Mr. J. C. Tallack was awarded first prize with Court Pendu Plat. Mr. A. J. Reid, gardener to F. C. Carr Gomm, Esq., Farnham Chase, was second with Golden Reinette.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. J. Fraser, C. T. Druery, H. B. May, H. Herbst, R. Dean, J. Hudson, J. Jennings, J. F. McLeod, H. S. Leonard, G. Nicholson, J. Fraser, R. M. Hogg, W. Bain, J. D. Pawle, E. Mawley, J. W. Barr, J. Walker, H. J. Jones, D. B. Crane, E. Beckett, G. H. Engleheart, and G. Paul.

Mr. J. R. Box, Croydon, arranged a very effective exhibit of Gloxinias and Maidenhair Ferns. Some of the varieties were of fine quality. The same exhibitor also sent a few flowers of double Begonias (silver-gilt Banksian medal). Five boxes of superb Maréchal Niel Roses were staged by Mr. J. Walker, Tbame. The blooms were solid, of good colour, and very fragrant (silver Flora medal). Mr. G. Mount, Canterbury, made himself conspicuous by staging a magnificent collection of Roses, including La France, Mrs. J. Laing, Captain Hayward, Ulrich Brunner, and many others (silver-gilt Flora medal).

Mr. Capp, gardener to Sir W. Peerson, Paddockhurst, Crawley, sent an exhibit comprised of Gloxinias and Zonal Pelargoniums. Messrs. W. Cutbush & Sons, Highbate, were represented by a group of bardy flowers, in which Doronicums, Primulas, and Alyssums were conspicuous (bronze Banksian medal). A large extent of tabling was occupied by Messrs. Barr & Son, Covent Garden, who showed a fine collection of their famous Tulips. English, Darwin, Cottage Garden, and Parrot sections were represented, and it was easy to realise from the method of arrangement how beautiful these flowers are from a decorative point of view. Flowers of all colours were shown, comprising all forms known in the Tulip world (silver Flora medal). On one side of the Drill Hall entrance was a fine bank of Roses, exhibited by Messrs. W. Paul & Son, Waltham Cross. Amongst others were noticed Gustave Piganeau, Charles Lefebvre, Duke of Edinburgh, Jeannie Dickson, La France, and Fisher Holmes, together with a box of cut blooms of Maréchal Niel that it would be difficult to beat. The firm also exhibited blooming plants of the new Tea Rose Enchantress (silver-gilt Flora medal).

Messrs. J. Cheal & Sons, Crawley, showed a small collection of hardy flowers and Violas. Among the former were Genistas, Pyruses, and Azaleas in variety (bronze Banksian medal). Messrs. Kemp & Wilson, Mortimer Street, W., showed floral designs in the shape of wreaths, bouquets, and baskets of flowers (bronze Banksian medal). Mr. J. Hudson, gardener to Messrs. De Rothschild, Gunnersbury House, sent flowers of Hymenocallis macrostephana tastefully arranged in an earthenware vase. Mr. B. Ladbams, Southampton, sent flowering plants of a new Pink, Diamond, with Tulipa flava and a Calla of large size. Pæonies were largely exhibited by Messrs. Kelway, Langport, being the first of the season. Amongst others Cardinal Vaughan, Diamond Jubilee, and Longest Reign were very striking (silver Banksian medal).

Messrs. Paul & Son, Cheshunt, were represented by hybrid Rhododendrons, Iris cristata, Trillium grandiflorum, Pyruses in variety, with Gemms, Roses, and other flowers, the whole making up an effective and interesting exhibit (silver Flora medal). Tulips in charming variety were exhibited by Messrs. Jas. Veitch & Sons, Chelsea. All sections were represented, and in addition to these flowers the firm showed Tritonias, Ixias, Deutzia hybrida Lemoinei, and Rubus idelicus (silver Banksian medal). Messrs. Thos. Cripps & Son, Tanbridge Wells, showed plants of Deutzia Lemoinei and a few Cypripediums. An interesting exhibit came from the Royal Gardens, Kew, comprising Rhododendrons Kewense, Luscombei, and cinnabarinum, with flowering branches of Cytisus purgans, Ribes speciosum, Pyruses Pingo and Schiedeckeri, and Amelanchier alnifolia.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, De B. Crawshaw, H. M. Pollett, J. T. Gabriel, W. H. Young, F. J. Thorne, H. J. Chapman, E. Hill, J. W. Bond, C. Pilcher, W. Cobb, J. Douglas, and H. Williams.

Mr. G. W. Cummins, gardener to A. H. Smees, Esq., The Grange, Wallington, staged a handsome collection of Orchids, comprised mostly of Cattleyas, Lælias, and Lælio-Cattleyas in splendid condition (silver Flora medal). Mr. Cragg, gardener to W. C. Walker, Esq., Percy Lodge, Winchmore Hill, sent a showy group of Orchids. There were Lælias, Cymbidiums, Odontoglossums, Cypripediums, and others (silver Flora medal). Messrs. F. Sander & Co., St. Albans, exhibited a small collection of Orchids. Amongst others Cattleya Mossiae, C. Skinneri virginale, C. Schrodæra alba, C. Wm. Murray, Odontoglossum vexillarium, and Masdevallias were conspicuous.

Very attractive were the Orchids sent by Messrs. J. Veitch & Sons, Ltd., from Chelsea. The arrangement of the several handsome plants at disposal was very effective, small Adiantums being used as a groundwork. Oncidiums and Odontoglossums were gracefully beautiful, Dendrobiums of splendid quality, Masdevallias showy, with Cymbidiums, Lælias, Cattleyas, and Cypripediums, aided in the general excellent effect (silver-gilt medal). Besides these prominent exhibits of Orchids, several smaller ones came from numerous exhibitors. Mr. Methven, gardener to Marquis Camden, Bayham Abbey, sent a fine Cattleya Mendeli with a spike carrying seven flowers.

CERTIFICATES AND AWARDS OF MERIT.

Anemia rotundifolia (W. Bull).—A graceful Fern with long fronds composed of round pinnae (first-class certificate).

Cypripedium Bellatulo-vexillarium (Mrs. Briggs-Bury).—A handsome hybrid. The colour of the dorsal sepal is white at the lower part, shading to deep claret at the margin. This, too, is the colour of the pouch. The petals are white, spotted and flushed claret (award of merit).

Cypripedium Chapmani magnificum (H. J. Chapman).—Deep claret is the colour of the lip of this beautiful Orchid. The broad petals are almost entirely covered with deep claret crimson spots. The round dorsal sepal is white at the margins, becoming maroon towards the base (award of merit).

Lælio-Cattleya Hippolyta, Dulcote variety (W. Cobb).—A superb form of the type (award of merit).

Lilac Senator Holland (W. Bain).—A handsome double variety. The truss is large, and the colour dark (award of merit).

Odontoglossum Andersonianum Bogaerdianum (D. B. Crawshaw).—The spots and blotches on this are very fine, being bright chocolate (award of merit).

Rhododendron Pink Pearl (J. Waterer).—This is a very beautiful variety, with large pink flowers (award of merit).

Streptocarpus achimenesiflora (J. Veitch & Sons, Ltd.).—This is a hybrid, resulting from a cross between a white-flowered hybrid and a *S. polyanthus*, evidences of which may readily be seen. The colour of the flower is pale blue (award of merit).

Trollius napellifolius (Barr & Sons).—The flowers of this are of medium size, and very rich in colour (award of merit).

RED SPIDER AND SICKLY GOOSEBERRY FOLIAGE.

ON page 338 Mr. G. R. Allis mentions the pale and sickly appearance of the foliage of Gooseberries and Currants, and attributes it to frost. Now, I have not seen the particular case to which he refers, and am not disputing it; but it is such a very common error to ascribe to frost what is really an attack of red spider, that I venture to call attention to it at the present time.

I was examining a large fruit plantation last week, and came across some bushes of Gooseberries as described, pale almost to whiteness, and their sickly appearance was apparent at a distance. I could see at a glance it was the old enemy, and by carefully plucking a few sprays in order not to dislodge them, I carried them to the "Rose and Crown" to show people and educate them in detecting early attacks.

The owner of the plantation came in, and asked me had I noticed how the frost had turned the foliage of the Gooseberries yellow. "No," I replied; "but you have the old enemy in force, and that is the cause." I asked the landlord for a sheet of white paper, and tapping the shoots sharply on it, hundreds of spiders were racing in every direction. Now, Mr. Editor, may I ask all fruit growers who are interested in this question to give this simple plan a test, and for the sake of information oblige with brief replies? I found out some years ago, when giving lectures on insect pests (illustrated under the microscope, as I have every season since), that these spiders (or mites) hatch out in the coldest and wettest weather in the beginning of February, and there remain, as those referred to have, through one of the wettest, coldest, and most unlikely seasons known. The red spider eggs on Apples and Plums are only just hatching out, and from the red eggs, young spiders appear identical to the Gooseberry spiders.—J. HIAM.

[Without for a moment suggesting that Mr. Allis was mistaken, we have no doubt Mr. Hiam is correct in his assumption that the mite known as red spider does much more harm to Gooseberry bushes early in the year than many persons suppose. What those persons want to know who have to deal with the enemy is the safest and surest method to pursue for its extirpation.]

THE YOUNG GARDENERS' DOMAIN.

FORCING FRENCH BEANS.

I THINK if "Stone Warrilow" were to give what he calls the "potting-on system" a trial he would find out it possessed some advantages. If the Beans are sown in 60's, and the plants transferred to larger pots of fresh sweet soil, it must be better than sowing in the fruiting pots, in which the soil is liable to get stagnant; and he would also find that he could pick Beans a week or two earlier than by the method he advocates. As to the crops, I am able to say that we pick twice the number of pods from our eight plants in a 16-size pot that he does from his sixteen plants in one of his 11-inch pots. Moreover, it would not do for us to wait till our Chrysanthemums are over before sowing, as we have picked two or three crops before then. My chief has taken the first prize with a collection of vegetables at a November show with French Beans as a weighty dish grown by our potting-on system.

"Stone Warrilow" says he cannot see any beneficial results arising from the use of liquid manure. Can he tell us why French Beans should not be benefited by liquid manure the same as are other plants? We find it is a great help both to the plants and the swelling of the pods. There is a gardener about a mile from us who used to sow his Beans in the fruiting pots, but seeing our system he has followed it ever since with much better results than before.—W. W.

VIOLETS.

THIS flower is held in the highest estimation for its exquisite and delicate perfume. There are many varieties, but it will be sufficient to describe the culture of a few of the best, as from the narration the treatment of the rest may be readily gathered. My favourite trio consists of Marie Louise, pale lavender; Neapolitan, mauve with white eyes; and Comte de Brazza or Swanley White.

These should be propagated in April. When the plants have flowered for the season remove them from the soil in which they have been grown, and divide them into single crowns, cutting off all runners, selecting the strongest only, and plant them 4 to 6 inches apart with a trowel in a cool frame, pressing the soil firmly round their roots; close the frame for a few days, and shade from bright sunshine until they show signs of growth.

When rooted, so that they can be removed with a ball, they should be transplanted to their summer quarters. A rich and well-prepared piece of ground with a north-west aspect suits them admirably; plant 9 inches asunder, and syringe them with pure water in the evenings of dry hot days, pinching off all runners as they appear, and keeping the bed free from weeds. Nothing more is required during the summer months.

For pot culture the best compost is formed of half turfy loam, half decayed manure and leaf mould, well mixed and turned over two or three times during summer. This should be ready for use by the end of September. At that time the plants must be removed from the bed with as much soil to their roots as possible. They should then be divested of all side shoots or runners and placed in 7-inch pots. The pots may be well drained with dried broken bones instead of potsherds, as the roots cling to the bones, which gives vigour to the plants, and makes them bloom more profusely. Weeds and decayed leaves must be removed, and water given when necessary, care being taken to wet the leaves as little as possible. In March and April, if the plants have been properly managed, they will produce abundance of flowers, and consequently require much more moisture than during winter.

To have an abundance of fine flowers of Russian Violets in the autumn and early spring, these should be planted in beds near a wall having a warm aspect. The soil should be light but very highly manured, with a large quantity of sand underneath the top soil. Plant in rows about 4 inches apart, and keep well watered. Every year in April, immediately after the plants have ceased flowering, the beds should be broken up, the soil renewed, and fresh plants put in for another year.—C. W. M.

THE MELON.

(Continued from page 397.)

To insure a good set, if the weather is at all favourable, air should have been admitted early, in order that the atmosphere of the house may be dry. If, on the other hand, it is dull or wet, additional pipe heat must be resorted to, but this ought not to be too fierce, as it would encourage red spider to make its appearance. As there are generally pollen-bearing and fruit-producing flowers open at the same time on each plant, pollen from the former should be transferred to the latter. If necessity compels fertilising with different varieties the fruits should be marked, and unless the seed be required for experimental purposes it must not be saved, as a mixture of varieties would occur, and at least some of them inferior.

When the fruits are set and swelling more atmospheric moisture will be required, but be careful with the syringe for some time, contriving to maintain a genial temperature by damping the walls and paths of the house rather than by syringing the plants. Should, however, red spider make its appearance the syringe must be resorted to, being careful not to wet the young fruits too much, or they may become marked and have an unsightly appearance. All through the growing period be very careful with ventilation, admitting a little air with a gradual increase is best, always striving to avoid draughts. When it is observed which fruits are swelling freely three will be sufficient on a plant if they are expected to be very fine. As swelling takes place more water will be required at

the roots, an occasional application of weak liquid manure or a light dressing with some proved fertiliser being very beneficial.

Supports must be placed under the fruits. Some growers use boards suspended by string, others nets made especially for the purpose, and both are good. As the fruits continue swelling copious supplies of water will be found necessary, never allowing the roots to become dry, or the Melons will crack and be useless. Continue occasional applications of liquid manure to help the fruit to attain to a good size. When fruits change colour less water will be required at the roots, and less moisture in the atmosphere, at the same time admitting more air, and then when the fruit is ripe it will be found of good flavour. To keep up successions sow at intervals of one month sufficient stock to replenish the whole space, or grow in pots, as the case may be.

It is advisable to renew the border after the fruits are ripe, also to thoroughly cleanse the house so that all insect pests may be eradicated, and a clean start made with the young stock. Melons are subjected to canker. On this being observed a little fine quicklime dusted on the affected part will be found an efficient remedy.—SEMPER.

BOUVARDIAS FROM ROOT CUTTINGS.

THE usual treatment of the Bouvardia is to dry the plants off after they have done flowering, and then to place them in heat to produce cuttings. The cuttings are taken with a heel when the young growths are 2 inches or 3 inches long, inserted in prepared pots, and placed in the propagating frame. I should like to bring to the notice of other young gardeners what I have found in practice to be a better system—namely, to propagate by root cuttings. To obtain these dry the plants off in the usual way, but instead of placing them in heat to make young growths shake them out of the pots, remove the soil from the roots, and cut them back to about an inch from the old stem. These roots are cut into lengths about 1½ inch long, and spread on the surface of prepared pans. Any light soil is suitable. Cover the roots about a quarter of an inch in depth with finely sifted soil, and place in the propagating frame or on a hotbed. The growths from these small pieces of roots will be found to almost equal in growth those from the plants introduced into heat, but with this difference—the growths from the roots are already plants, while those from the plants have still to be rooted. And it is here the great saving in time comes in; while the cuttings are making roots the rooted cuttings are making plants, and so gaining a great advantage. After a thorough trial of both systems I should be sorry to return to cuttings for producing strong plants for decorative purposes.—J. C., Lancashire.

THE APPLE.

THE Apple, *Pyrus Malus*, natural order Rosaceæ, is a native of the British Isles and most parts of Europe. It is the most useful of all cultivated fruits, and probably the most extensively grown. The Crab was known in the earliest times, and our cultivated Apple was most likely introduced by the Romans. Pliny, the Roman historian and naturalist, knew over twenty varieties. The Apple, as Mr. Wright says in the "Fruit Growers' Guide," is the rich man's fruit and the poor man's fruit, and should be planted in every garden.

SOIL.—The Apple does best in loam containing a little sand. In such a medium Apples colour well and grow to a large size; the trees continue in health and bearing, and are seldom attacked with disease. A deep soil is not required to grow Apples in, 2 feet being ample. In wet localities the ground will require to be well drained before planting Apple trees, as they generally do better in dry than wet soils if not thoroughly drained.

SITUATION.—An open position, facing south, east, or west, sheltered from the east, as wind from that quarter is so prevalent when Apple trees are in flower.

STOCKS.—Mr. Rivers has raised several varieties of Paradise stock from seed, and they are remarkable for promoting early fruitfulness in Apple trees worked on them. The French Paradise is supposed to be the best dwarfing stock for dessert Apples, and all worked on it come into bearing quickly, give heavy crops, and in wet districts are free from canker when those on Crab or free stocks are not. The Crab is the best stock for standard and half-standard Apple trees, and is noted for its hardiness.

PRUNING.—That the knife is too much used on Apple trees in most gardens is my opinion, and instead of cutting back every year I would, if possible, not prune at all after the heads are formed, except to take out any branches that are too close or badly placed. After a couple of years all buds will be fruit buds where, under close pruning, there would be nothing but growth. If Apples on Paradise stocks grow too strongly and do not fruit freely lift and replant the trees, using some fresh loam if procurable. If on the Crab or free stock root-pruning is best, cutting a trench round the trees and filling with fresh loam. Mulch round the trees after either operation—in fact, all fruit trees are the better for a mulching every year; it arrests evaporation and prevents some soils from cracking in dry weather.
